Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AG-DRY-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

AG-WET-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

HG-WET-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (WET)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Sample Parameter Qualifier Key:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAF-SK	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

ALS Test Code	Matrix	Test Description	Method Reference**
MET-200.2-CCMS-SK	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend & Qualifier Definitions:

EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended.
EHTR: Exceeded ALS recommended hold time prior to sample receipt.
EHTL: Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.
EHT: Exceeded ALS recommended hold time prior to analysis.
Rec. HT: ALS recommended hold time (see units).

Notes*:
Where actual sampling date is not provided to ALS, the date (& time) of receipt is used for calculation purposes.
Where actual sampling time is not provided to ALS, the earlier of 12 noon on the sampling date or the time (& date) of receipt is used for calculation purposes. Samples for L1842861 were received on 13-OCT-16 13:00.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Sample Parameter Qualifier Key:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAF-SK	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

ALS Test Code	Matrix	Test Description	Method Reference**
MET-200.2-CCMS-SK	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

	33	23-SEP-16	27-OCT-16 14:00	28	34	days	EHT

Legend & Qualifier Definitions:

EHTR-FM:	Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended.
EHTR:	Exceeded ALS recommended hold time prior to sample receipt.
EHTL:	Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.
EHT:	Exceeded ALS recommended hold time prior to analysis.
Rec. HT:	ALS recommended hold time (see units).

Notes*:
Where actual sampling date is not provided to ALS, the date (& time) of receipt is used for calculation purposes.
Where actual sampling time is not provided to ALS, the earlier of 12 noon on the sampling date or the time (& date) of receipt is used for calculation purposes. Samples for L1844932 were received on 18-OCT-16 14:10.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AG-DRY-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

AG-WET-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

HG-WET-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (WET)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

APPENDIX C

DEVELOPMENT OF BACKGROUND CONCENTRATIONS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX C: DEVELOPMENT OF BACKGROUND CONCENTRATIONS

C.1 Introduction

This overview provides the development of background concentrations in soil, surface water, and sediment for use in the Human Health Risk Assessment (HHRA) and Ecological Risk Assessment (ERA).

C.1.1 Background

Many jurisdictions use an upper confidence level (95^{th} or 98^{th} percentile) to represent background as these percentiles encompass a large portion of variation in background whilst excluding extremes. These upper confidence levels represent the highest concentration that is likely to represent background. Regulatory agencies such as the British Columbia Ministry of Environment (BC MOE) and Ontario Ministry of the Environment and Climate Change (MOECC) use this definition of background for setting cleanup standards/criteria.

The Canadian Council of Ministers of the Environment (CCME) in developing more recent soil guidelines for nickel (2015), beryllium (2015), and barium (2013) have used an arithmetic average for defining background.

The Federal Contaminated Sites Action Plan (FCSAP) background document (FCSAP 2015) refers to guidance from the United States Environmental Protection Agency (U.S. EPA 2002) for developing an appropriate background concentration. This guidance uses an average concentration for background when comparing to exposure areas to determine the difference between background and exposure areas. In the Exposure Section of the FCSAP document (2015), they indicate that if there is a suitable sample size (N>10) then conditions within the background area should be based on the 95% upper confidence level of the mean (95% UCLM).

The Giant Mine risk assessment follows the FCSAP (2015) guidance and use an average statistic to describe background in the screening for selection of COPC (see Appendix D) and the 95% UCLM to describe background within the risk assessment calculations.

C.1.2 Review of Selected COPC

During the COPC selection process (Appendix D), measured concentrations were compared to average background concentrations to determine which constituents are elevated above natural levels. The constituents that were above criteria and identified as constituents of potential concern (COPC) in the stage of the HHRA (discussed in Appendix F) and ERA (discussed in Appendix K) are as follows:

Table C.1 Soil, surface water, and sediment COPCs identified in the ERA

COPC	Soil	Surface Water	Sediment
Antimony	✓	✓[ab]	✓[d]
Arsenic	✓	✓[ab]	✓[ab]
Chloride		✓[c]	
Chromium			✓[ab]
Copper	✓	X	✓[ab]
Lead			✓[b]
Manganese	✓	X	
Mercury			✓[b]
Sulphate		✓[c]	
Zinc	✓	x	✓[b]

Note: x – although constituent not identified as a COPC in this media, background concentrations were calculated to determine total intakes based on the receptor diet/ habitat.
a – This is a COPC identified in Yellowknife Bay.
b – This is a COPC identified in Baker Creek.
c – This is a COPC identified in Baker Creek and Yellowknife Bay in the future.
d – Carried through as identified as a COPC in surface water.

Table C.2 Soil and surface water COPCs identified in the HHRA

COPC	Soil	Surface Water
Antimony	✓	x
Arsenic	✓	✓[a]
Cadmium	✓	NA
Lead	✓	NA
Manganese	✓	x
Vanadium	✓	NA

Note: No human health guidelines available for sediment, so the COPC identified in soil were selected as sediment COPCs.
a – arsenic was not identified as a COPC in surface water but was evaluated due to community concerns.
x – although constituent is not a COPC in this media, background concentrations were calculated to determine total intakes based on the receptor diet.
NA – background surface water concentrations not needed for these COPC as a qualitative assessment was carried. Please refer to Appendix F for details.

C.1.3 Previous Discussions of Background for Soils in Yellowknife Area

Risklogic (2002) used data available from the GSC, as well as other data around Yellowknife to develop an average natural background concentration of arsenic of 150 mg/kg with an upper limit of normal (90th percentile of the distribution) of 300 mg/kg. The average arsenic concentration was based on data from Kerr (2001) which included samples from the Giant Mine as well as in the City of Yellowknife.

Ollson (2000) in his Master's thesis used principal component analysis and determined that the background range of arsenic concentrations in Yellowknife soils ranged from 4 to 70 mg/kg with a median of 32 mg/kg. Ollson (2003) in his PhD thesis again used principal component analysis and determined that the natural background concentration for arsenic in Yellowknife ranged from 3 to 150 mg/kg although it could be as high as 300 mg/kg. He also indicated that 99.5 % of the samples had concentrations less than 150 mg/kg. The median concentration for background was 32 mg/kg with an average concentration of 58 mg/kg. Table 2-1 in the thesis indicated that four samples collected from the Grace Lake area had concentrations ranging from 54 to 110 mg/kg with an average arsenic concentration of 81 mg/kg and a standard deviation of 30 mg/kg.

Bromstad (2011) provides the following discussion "Kerr (2006) has determined regional background values for the Yellowknife area that are significantly lower than 150 ppm (3 - 79 ppm As depending on the underlying bedrock type)".

Kerr (2006) provides a table (Table 20-2) summarizing the regional background concentrations of antimony and arsenic in till samples. He indicated that regional till samples over volcanics had background antimony concentrations in the range of 0.1 to 0.5 mg/kg and arsenic concentrations in the range of 10 to 30 mg/kg. For till samples over metasediments and over granite, regional background concentrations range from 0.1 to 0.2 mg/kg and arsenic concentrations range from 5 to 10 mg/kg. However, it should be noted that *in situ* weathered volcanics and meta sediments can have antimony concentrations as high as 11 mg/kg and arsenic concentrations as high as 1500 mg/kg and Kerr indicates that these samples are "anomalies with concentrations significantly above estimated background values for till".

The data from Kerr (2006) as well as the information provided in the two theses by Ollson (2000, 2003) support the assertion that the average background arsenic concentration in soil for the Yellowknife area is less than 150 mg/kg.

C.2 Background Concentrations in Soil

The FCSAP guidance (2015) indicates that background is representative of the true range of concentrations associated with the geographic area of the site. Thus, the background soil samples selected for use in the risk assessment were for areas in the local area around the Giant Mine but outside of the area of influence.

The Geological Survey of Canada (GSC) has compiled till soil data (Kerr 1999, 2000, 2001) associated with the geographical area of the Giant Mine and this dataset was used to determine the background soil concentrations for use in the risk assessment. It should be noted that this dataset has also been used to develop the background concentrations in support of the GNWT clean-up criteria for arsenic and is considered to be appropriate for use to establish background for the risk assessment. There are samples collected from various programs in and around the Yellowknife area (City of Yellowknife, Ndilo, Dettah etc.) that fall within the range of the concentrations found in the GSC dataset. These data could be used to augment the GSC database; however, as these are areas that are considered to be exposure locations in the HHRA, a decision was made not to consider these data for the determination of background. Appendix O provides concentrations in all the samples that were considered as background.

The GSC dataset has samples present in the Yellowknife Greenstone Belt (YGB), which is considered to reflect a mineralogy that is similar to the Giant Mine, as well as locations around Yellowknife and the Giant Mine Site. Data obtained from the GSC database were analysed using instrumental neutron activation analysis (INAA) technique. However, this analytical technique was not used for several COPC (i.e., lead, manganese, and vanadium); consequently, inductively coupled plasma atomic emission spectrometry (ICP-AES) analyses from the GSC database were also considered to establish background conditions. The INAA analysis technique considers larger sieved fractions of 0.063 mm or less while the ICP-EAS soil samples were sieved into particle fractions of 0.002 mm or less.

A comparison of the concentrations of the COPC within the regional and YGB only datasets was conducted to determine whether the data between these two areas are statistically different. This comparison was completed for antimony and arsenic as only these two COPC have analytical data in both the regional and YGB area.

C.2.1 Development of Background Soil Concentrations

The development of the statistics for background was as follows:

1. Soil samples from the GSC collected at depth (10 cm to 60 cm) were included in the datasets for establishing background concentrations representative of current conditions. Samples collected as these depths would be unimpacted by any possible aerial deposition from the Giant Mine. This dataset was infilled with some more recent data from Stantec (2014a), Stevens (2015), and Golder (2016a). Although these samples were not explicitly collected at depth (i.e., from the top 20 cm), the samples are also not strictly surficial soil samples and could therefore include surficial soil mixed with undisturbed soil. Furthermore, the inclusion of these samples is conservative as the mean arsenic concentration decreased from 69 mg/kg to 66 mg/kg.

2. Samples associated with the Giant Mine site and the City of Yellowknife were excluded from the dataset as they were considered to be affected by mining activities.

3. For developing the background concentration (95% UCLM), the MDL was used in the dataset and input into ProUCL. ProUCL is a statistical program that provides 95% UCLM recommendations (based on data distribution, dataset size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate, in these cases, the highest appropriate 95% UCLM was selected. It is noted that the CCME (2016) suggest that the BCA bootstrap approach from ProUCL can be used for the majority of datasets, the selection of the highest 95% UCLM, that may be greater than the BCA bootstrap recommendation, is therefore a conservative approach.

C.2.1.1 Regional Background Soil Concentrations

The sample locations used to develop the regional background soil concentrations are shown in Figure C.1. The regional background is a combination of the Stevens (2015), Stantec (2014a) and Golder data (2016a) and the entire GSC database with the exception of samples from the Giant Mine and the City of Yellowknife (i.e., all locations shown in Figure C.1 with the exception of those shown in purple). Table C.3 provides a summary of the regional background statistics for the identified human health COPC.

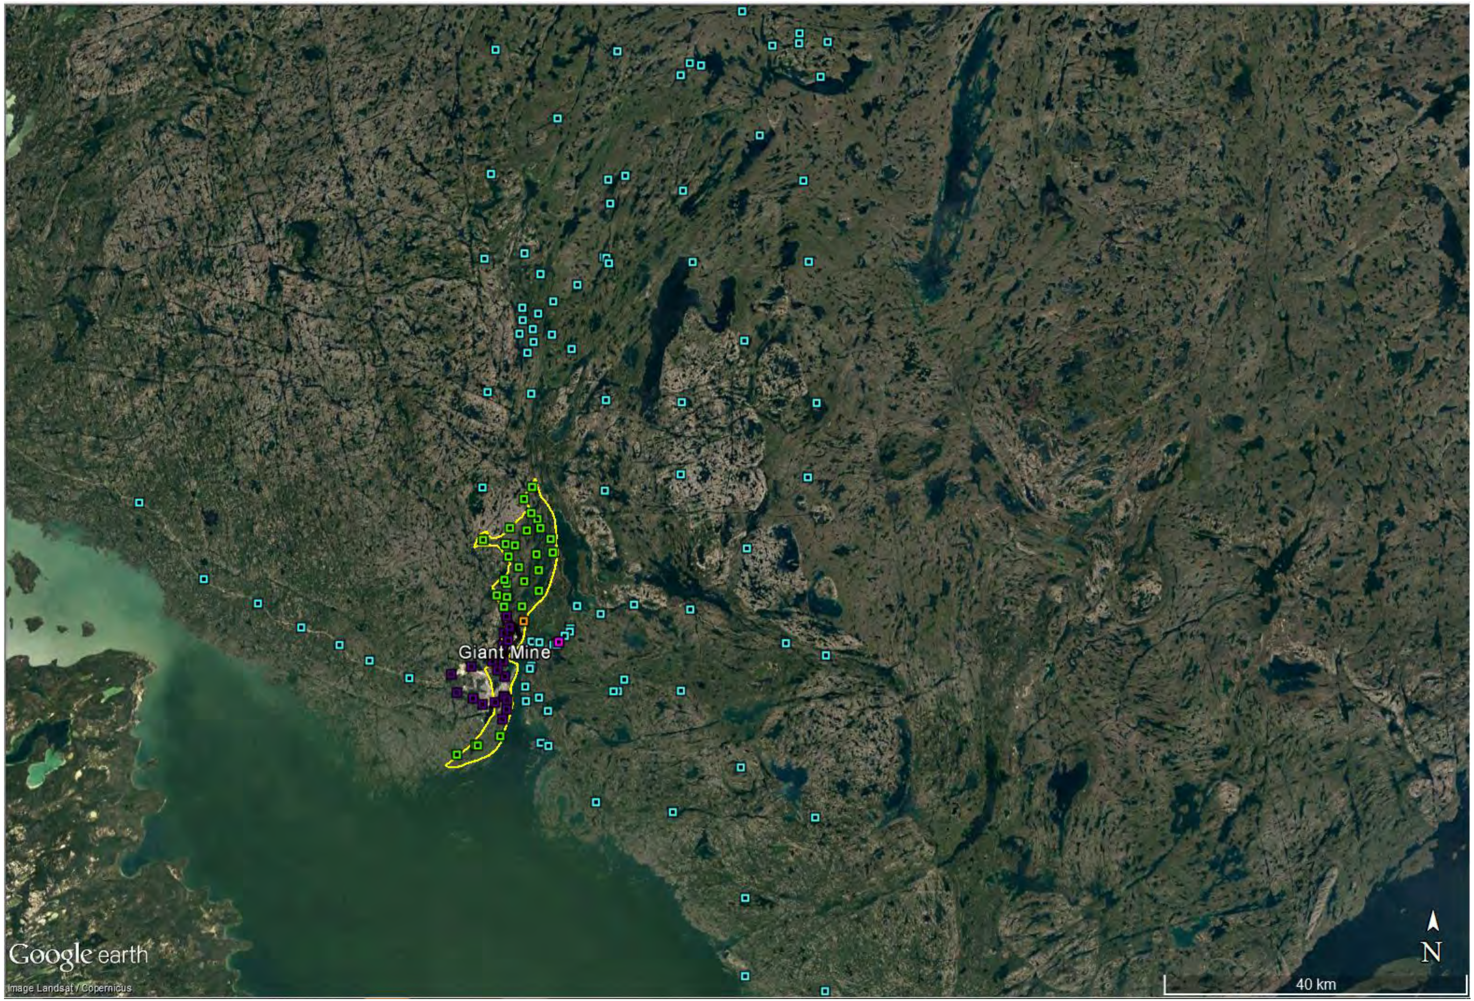
It should be noted that the GSC database analysed the soils using two different techniques:

- For antimony, arsenic, and zinc, data were available for soils analysed using the INNA technique which captures particles <0.063 mm.
- For cadmium, copper, lead, manganese, and vanadium, data were available for soils based on the ICP-EAS technique which captures smaller particles of soil <0.002 mm.

The other samples included in the database of regional background are as follows:

- Data from nine (9) samples from Stevens (2015) were included (arsenic only). It is stated that samples were analyzed by Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES) of an acid digested matrix.
- Data from one (1) sample from Golder (2016a) was included (arsenic only). It is stated that samples were analyzed by Inductively Coupled Plasma Mass Spectrometry (ICP-MS).
- Data from one (1) sample from Stantec (2014a) was included (arsenic only). It is stated that samples were analyzed by Inductively Coupled Plasma Mass Spectrometry (ICP-MS).

Figure C.1 Background soil sampling locations



- GSC data collected from outside of the Yellowknife Greenstone Belt
- GSC data collected from the city of Yellowknife and the Giant Mine site (not included in background data set)
- GSC data collected from the Yellowknife Greenstone Belt
- Golder (2016a) and Stantec (2014a) sampling location
- Approximate vicinity of Stevens (2015) sampling (exact locations not known)
- Yellowknife Greenstone Belt

Table C.3 Summary statistics for regional background soils

COPC	N	N < MDL	Soil Concentration (mg/kg) [c]						
			Min	Max	Mean	SD	Geo Mean	95th Percentile	95% UCLM
Antimony[a]	120	25	0.05	11	0.65	1.3	0.3	3.0	1.2
Arsenic[a]	131	0	2.4	1500	66	199	22	181	142
Cadmium[b]	54	54	2.5	2.5	NA	NA	NA	NA	NA
Copper[b]	54	0	5	128	27	20	22	59	31
Lead[b]	54	0	15	31	20	3.2	20	26	21
Manganese[b]	54	0	165	1505	316	221	285	452	369
Vanadium[b]	54	0	25	193	68	31	63	118	75
Zinc[a]	119	66	25	299	78	61	62	224	95

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean.

a – Soil samples were analysed primarily using the INAA technique (<0.063 mm fraction).

b – Soil samples were analysed using the ICP- EAS technique (<0.002 mm fraction).

c – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

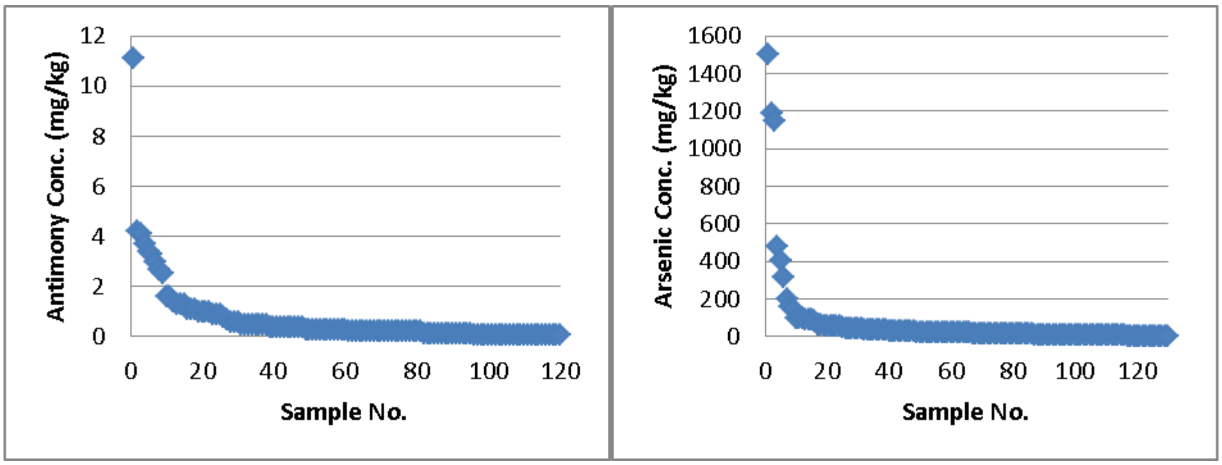
As seen from Table C.3, all samples of cadmium were reported at levels below the MDL, therefore a background concentration could not be confidently calculated for this COPC.

There are elevated concentrations of manganese in the ICP-EAS analysed soil data. The ICP-EAS soil samples were sieved into particle fractions of 0.002 mm or less. According to the World Health Organization (WHO 2004) an estimated 80% of the manganese in suspended particulate matter is associated with particles of 0.005 mm or less. Thus, the smaller particles of sieved soils in the ICP-EAS dataset could explain the elevated concentrations of manganese in background samples.

As seen from Table C.3, there is a significant difference in the (arithmetic) mean and geometric mean in the antimony and arsenic datasets suggesting that the data are skewed and there is a potential for outliers. The geometric mean or median can be taken as the best representation of the central tendency of a skewed distribution. Unlike an arithmetic mean, the geometric mean tends to lessen the effect of very high or low values, which might bias the arithmetic mean. Consideration was given to using an upper confidence limit of the geometric mean rather than the 95% UCLM as a measure of background but the use of this statistic has not been discussed in any guidance documents. Therefore further investigation was given to the underlying data as discussed below.

The antimony and arsenic datasets were plotted to visually inspect the sample distribution (Figure C.2). Additionally, a skew test was conducted on these datasets resulting in values of 5.3 mg/kg and 5.7 mg/kg for antimony and arsenic, respectively, indicating that the datasets are positively skewed and further investigations were warranted.

Figure C.2 Concentrations of antimony (left) and arsenic (right) in regional background soils



It is apparent from Figure C.2 that the samples at high concentrations seem to be a different population from the bulk of the dataset. To investigate whether these samples represented outliers in the dataset, the data was log transformed and z-scores were calculated. A z-score is a standard score that indicates how many standard deviations a sample is from the mean. Any observation with a z-score less than -2.5 or greater than +2.5 is considered an outlier (PennState 2016). For arsenic, the z-scores for the three maximums (i.e., 1500, 1190, and 1150 mg/kg) all were greater than 3. For antimony, the maximum (i.e., 11.1 mg/kg) also had a z-score greater than 3. It should be noted that the maximum antimony sample is the same as the sample where arsenic was measured at a concentration of 1190 mg/kg. An additional test, the interquartile range (IQR), confirmed that the maximums were outliers. Therefore, these outliers may not be representative of typical background conditions and were omitted from the datasets.

Table C.4 provides the updated summary statistics for background regional soils for antimony and arsenic with the outliers omitted. As seen from Table C.4, the range of background concentrations for antimony is 0.05 mg/kg to 4.2 mg/kg and the range of background concentrations for arsenic are 2.4 to 482 mg/kg. The mean concentrations of antimony and arsenic are 0.56 mg/kg and 37 mg/kg respectively and the 95% UCLM concentrations are 0.91 mg/kg and 41 mg/kg, respectively. This demonstrates that the three samples that are from a different population representing weathered rock had a strong influence on the mean and 95% UCLM. The mean background concentrations in Table C.4 are similar to the range of concentrations provided in Kerr (2006) as representative of regional till background.

Table C.4 Summary statistics for antimony and arsenic in background regional soils – outliers removed

COPC	N	N < MDL	Soil Concentration (mg/kg) [a]						
			Min	Max	Mean	SD	Geo Mean	95^{th} Percentile	95% UCLM
Antimony	119	25	0.05	4.2	0.56	0.9	0.26	2.7	0.91
Arsenic	128	0	2.4	482	37	64	20	100	41

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95^{th} upper confidence level of the mean.
a – Summary statistics for Min, Max, Mean, SD, Geomean, and 95^{th} percentile were calculated using one half the method detection limit.

C.2.1.2 Yellowknife Greenstone Belt (YGB) Soil Concentrations

There are 28 samples for antimony, 37 samples for arsenic, and 27 for zinc from the YGB. The dataset includes GSC data and that from Stevens (2015). No data exist for the other COPC. Figure C.3 shows the sampling locations while the summary statistics are provided in Table C.5.

Figure C.3 Background soil sampling locations within the Yellowknife Greenstone Belt

Table C.5 Summary statistics for antimony and arsenic in YGB soils (mg/kg)

COPC	N	N < MDL	Soil Concentration (mg/kg) [a]						
			Min	Max	Mean	SD	Geo Mean	95th Percentile	95% UCLM
Antimony	28	1	0.05	11	1.9	2.2	1.1	4.2	2.9
Arsenic	37	0	5	1500	134	310	42	624	185
Zinc	27	13	25	299	99	89	67	284	137

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean.

a – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

Similar to regional background soils, there is a significant difference in the (arithmetic) mean and geometric mean, particularly in the arsenic dataset, suggesting that the data are skewed and there is potential for outliers. A skew test was conducted on the datasets resulting in values of 3.0 and 3.7 for antimony and arsenic, respectively, indicating that the datasets are positively skewed and further investigations are warranted. Additionally, the datasets were plotted to visually inspect the distribution (Figure C.4).

To investigate whether there were outliers in the YGB datasets z-scores were calculated. For antimony, the maximum (i.e., 11.1 mg/kg) had a z-score greater than 3. For arsenic, the z-scores for the two maximums (i.e., 1500, and 1190 mg/kg) were greater than 3. An additional two statistical tests, the IQR and the three times the standard deviation plus the mean, confirmed that the maximums were outliers. Therefore, these outliers may not be representative of typical background conditions and were removed from the dataset.

Table C.6 provides the summary statistics in background YGB soils for antimony and arsenic with the outliers omitted. As seen from this table, the antimony and arsenic background concentrations are higher in the YGB.

Figure C.4 Concentrations of antimony (left) and arsenic (right) in background Yellowknife Greenstone Belt soil

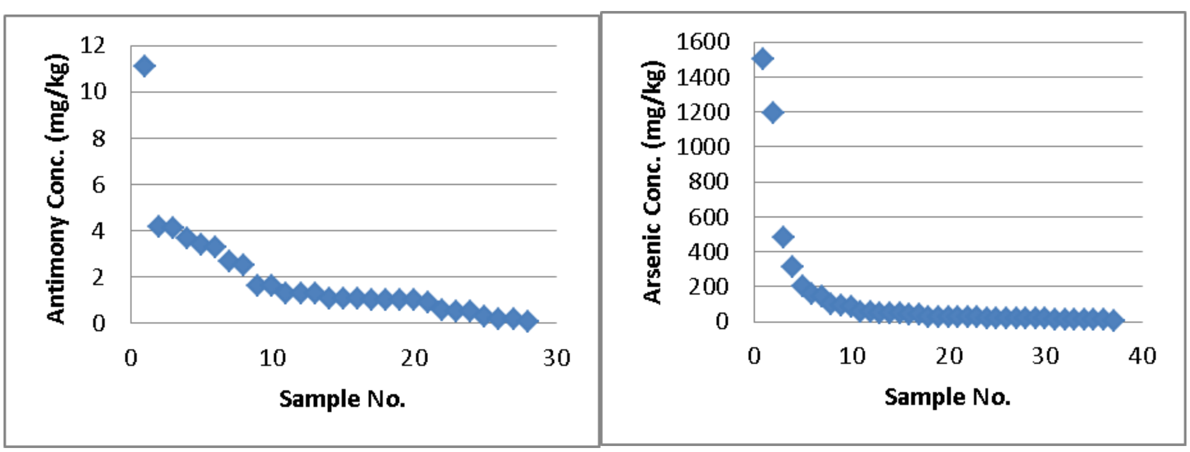


Table C.6 Summary statistics for Yellowknife Greenstone Belt background soils – outliers removed (mg/kg)

COPC	N	N < MDL	Soil Concentration (mg/kg) [a]						
			Min	Max	Mean	SD	Geo Mean	95th Percentile	95% UCLM
Antimony	27	1	0.05	4.2	1.5	1.2	1.0	4.0	2.2
Arsenic	35	0	5	482	65	97	35	236	94

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean.

a – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

Table C.7 provides a summary of the mean and 95% UCLM for antimony and arsenic for the different datasets that were described above. As seen from the table, the outlier concentrations do not significantly affect the mean or the 95% UCLM for antimony. However, for arsenic, the outliers (3 samples) have a strong influence on the mean and 95% UCLM. From a risk assessment standpoint, it was determined that the dataset that had the outliers removed provides a better representation of the background for arsenic and antimony.

Table C.7 Summary of the mean and 95%UCLM for arsenic and antimony at regional and YGB locations (mg/kg)

COPC	Statistic	Soil Concentration (mg/kg)			
		Regional		Yellowknife Greenstone Belt	
		Entire Dataset	Without Outliers	Entire Dataset	Without Outliers
Antimony	Mean	0.65	0.56	1.9	1.5
	95%UCLM	1.2	0.91	2.9	2.2
Arsenic	Mean	66	37	134	65
	95%UCLM	142	41	185	94

C.2.2 Summary

Table C.8 provides a summary for the background concentrations for soil used in the risk assessment. The 95% UCLM was used to describe background as indicated in the FCSAP (2015) guidance document.

All the data for cadmium were non-detect and thus a background soil concentration could not be developed. This does represent a data gap; however, the fact that cadmium is a non-carcinogen, the total measured concentrations, which include background, are what are considered in the risk assessment. In addition, additional screening for the various exposure areas indicates that measured concentrations of cadmium are generally low and below criteria with the exception of the City of Yellowknife.

For manganese, the minimum concentration of 165 mg/kg was used to describe background, as the range of background concentrations (especially the minimum concentration) seem high in comparison to the measured data at the exposure locations. This represents a conservative approach.

As seen from Table C.8, only regional samples are available for lead, manganese, and vanadium; therefore the 95% UCLM of the regional background data were used in the risk calculations. For antimony and arsenic, background derived from the Greenstone Belt was used for exposure locations at the Giant Mine, Ndilo, Latham Island, Ingraham Trail, Former Townsite, and the City of Yellowknife as these locations are all within the Greenstone Belt. For Dettah, which is outside the Greenstone Belt, the regional background concentrations for antimony and arsenic were used.

Table C.8 Summary of background concentrations for use in the risk assessment

COPC	Soil Concentration (mg/kg)		
	CCME Soil Quality Guideline	Regional Background 95% UCLM	Yellowknife Greenstone Belt Background 95% UCLM
Antimony	20	0.91	2.2
Arsenic	12	**41**	**94**
Cadmium	1.4	ND	ND
Copper	63	31	ND
Lead	70	21	ND
Manganese	-	165*	ND
Vanadium	130	75	ND
Zinc	200	94	137

Note: ND – No data available for this COPC. No soil guideline is available for this COPC
* The minimum concentration is being used for background as the manganese concentrations are higher than at exposure locations.
Values highlighted in grey exceed the CCME (Agricultural land use) guideline.

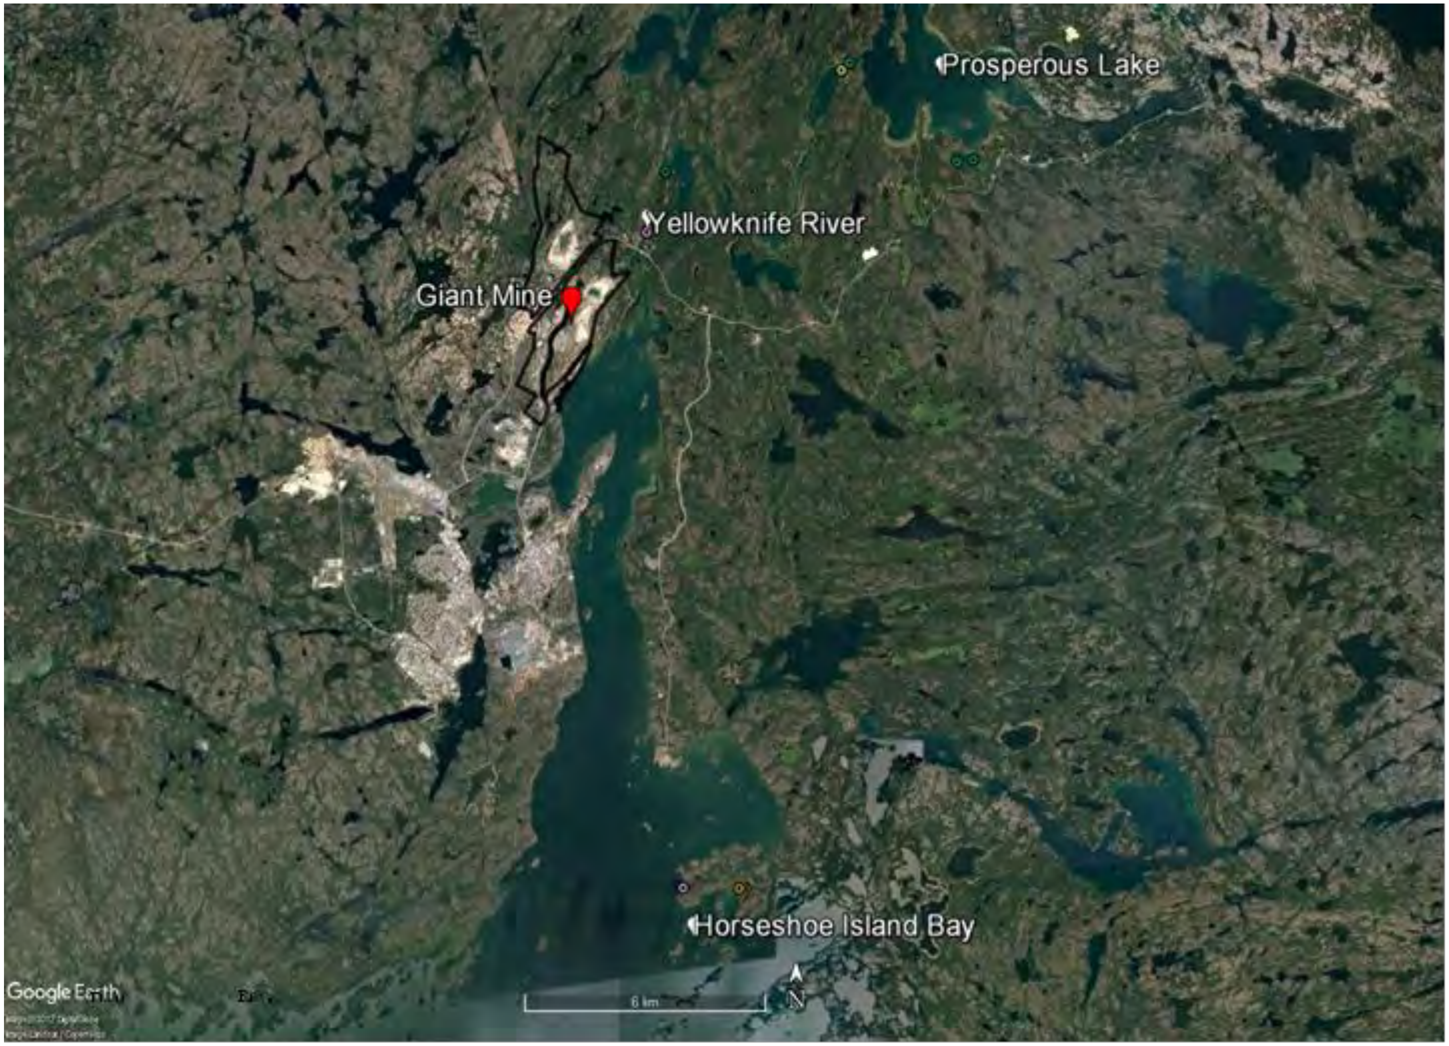
C.3 Surface Water Background Concentrations

The background locations that were considered for surface water are presented in Figure C.5. There have been four surface water studies in recent years where sampling was carried out at background locations (DCNJV 2012; Golder 2012, 2013; Stantec 2014b).

The background locations were based on the ones generally used for the aquatic studies related to the Giant Mine Project and have been identified as Yellowknife River and Horseshoe Island located in Yellowknife Bay. However, there have been a few studies that have used Prosperous Lake as a background location. It should be noted that Prosperous Lake is located approximately 12 km northeast of Giant Mine and away from the direction of prevailing winds. Given that Prosperous Lake has not been used a background location in many of the aquatic reports, a comparison of surface water data from Prosperous Lake to surface water data from other background locations was conducted to determine if it should be included as a background location. Additionally, a statistical analysis (Student's t-test, alpha = 0.05) was conducted to determine if there was a significant difference between COPC levels in different background locations.

The surface water ecological COPCs include antimony, arsenic, chloride, and sulphate. Arsenic is also considered for human health. The COPCs identified in ecological soil screening were also considered in the development of background for surface water (antimony, arsenic, copper, manganese, and zinc).

Figure C.5 Background surface water sampling locations



C.3.1 Development of Background Surface Water Concentrations

Similar to the soils, the 95% UCLM was used to describe background in surface waters following FCSAP guidance. Surface water samples from recent years (e.g., 2011 to present) were considered representative of current background conditions. Since the JoJo Tailings release occurred in May 2011, only data after this time were used in the assessment. Appendix O provides concentrations in all the samples that were considered as background.

The approach for developing surface water background for COPC was as follows:

- For estimating the 95%UCLM: The MDL was used (and identified as such) in the dataset used in ProUCL. ProUCL is a statistical program that provides 95% UCLM recommendations (based on data distribution, dataset size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate, in these cases, the highest appropriate 95% UCLM was selected.

To determine if the concentrations of COPC were similar from Horseshoe Island in South Yellowknife Bay and Yellowknife River, the following approach was used for statistical comparisons of the datasets:

1. An F-test was conducted on the Horseshoe Island and Yellowknife River datasets to determine if the variances were equal or unequal. If the F-Statistic is greater than the F critical value (one-tail), then the variances are considered unequal. If the F-test statistic is less than the F critical value (one-tail), then the variances are considered equal.

2. Based on the conclusion of the F-test, a Student's t-test was conducted assuming either equal or unequal variances. If the t-test statistic is greater than the t-distribution critical value (two-tail), the null hypothesis is rejected and the datasets are considered significantly different. If the t-test statistic is less than the t-distribution critical value (two-tail), the null hypothesis cannot be rejected and the datasets are not considered significantly different.

C.3.1.1 Selection of Appropriate Dataset for Background Surface Water Concentrations

Summary statistics were calculated to determine if Prosperous Lake differed from Horseshoe Island and Yellowknife River and to evaluate its suitability for inclusion in surface water background. Due to a small sample size for all COPC, a full statistical analysis could not be conducted reliably; therefore a simple comparison of summary statistics was used. A summary is provided in Table C.9.

Table C.9 Summary statistics for COPC concentrations in surface water from background locations

COPC	Location	N	N<MDL	Water Concentration (mg/L) [a]				
				Min	Max	Mean	SD	Geomean
Antimony	Prosperous Lake	3	3	$2.0x10^{-4}$	$2.0x10^{-4}$	NA	NA	NA
	Horseshoe Island	8	7	$1.5x10^{-4}$	$2.0x10^{-4}$	$1.9x10^{-4}$	$1.8x10^{-5}$	$1.9x10^{-4}$
	Yellowknife River	8	8	$2.5x10^{-5}$	$2.0x10^{-4}$	$1.2x10^{-4}$	$8.7x10^{-5}$	$8.4x10^{-5}$
Arsenic	Prosperous Lake	3	1	$2.0x10^{-4}$	$4.6x10^{-4}$	$3.7x10^{-4}$	$1.5x10^{-4}$	$3.5x10^{-4}$
	Horseshoe Island	8	0	$3.7x10^{-4}$	$7.6x10^{-4}$	$5.0x10^{-4}$	$1.2x10^{-4}$	$4.8x10^{-4}$
	Yellowknife River	8	0	$3.3x10^{-4}$	0.0013	$4.9x10^{-4}$	$2.9x10^{-4}$	$4.5x10^{-4}$
Chloride	Prosperous Lake	3	0	1.9	2.2	2.1	0.12	2.1
	Horseshoe Island	8	0	2.3	6.4	5.5	1.4	5.2
	Yellowknife River	8	0	1.6	2.6	2.0	0.26	2.0
Copper	Prosperous Lake	3	2	0.005	0.0011	$7.0x10^{-4}$	$3.5x10^{-4}$	$6.5x10^{-4}$
	Horseshoe Island	8	2	0.005	0.0017	0.0011	$4.2x10^{-4}$	$1.0x10^{-3}$
	Yellowknife River	8	4	$5.0x10^{-4}$	$1.3x10^{-3}$	$7.4x10^{-4}$	$3.1x10^{-4}$	$6.9x10^{-4}$
Manganese	Prosperous Lake	3	1	0.001	0.0043	0.0029	0.0017	0.0025
	Horseshoe Island	8	8	0.001	0.0025	0.0016	7.8×10^{-4}	0.0014
	Yellowknife River	8	3	0.001	0.009	0.003	0.0025	0.0025
Sulphate	Prosperous Lake	3	0	3.1	3.2	3.1	0.067	3.1
	Horseshoe Island	8	0	4.3	21	17	5.4	16
	Yellowknife River	9	0	2.7	3.8	3.3	0.3	3.3
Zinc	Prosperous Lake	3	3	0.002	0.002	NA	NA	NA
	Horseshoe Island	8	6	0.002	0.011	0.0035	0.0032	0.0028
	Yellowknife River	8	8	0.0015	0.002	0.0018	$2.6x10^{-4}$	0.0018

Note: Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean.

a – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

As seen from Table C.9, COPC concentration ranges (i.e., minimum and maximum concentrations) in Prosperous Lake were similar to other background locations. The majority of surface water samples of antimony and cyanide were below the MDL in both Prosperous Lake and other background locations. This comparison demonstrates that Prosperous Lake can be included in the determination of background.

Statistical analyses were then conducted for Horseshoe Island and Yellowknife River datasets to determine if these datasets were similar (Table C.10). There were enough data to carry out the comparison for arsenic, chloride and copper. Inferences were made for the other COPC. Since arsenic was the primary COPC, the analysis was considered to be appropriate.

Table C.10 Statistical comparison of surface water COPC concentrations in Horseshoe Island and Yellowknife River

COPC	Comparison	F-test Statistic > F-distribution Critical Value (one-tail)	*t*-test Statistic > *t*-distribution Critical Value (two-tailed)	Conclusion
Arsenic	Horseshoe Island vs. Yellowknife River	Yes, the variances are not equal	No, cannot reject the null hypothesis	Arsenic levels in Horseshoe Island surface waters are not statistically different than Yellowknife River.
Chloride	Horseshoe Island vs. Yellowknife River	Yes, the variances are not equal	Yes, reject the null hypothesis	Chloride levels in Horseshoe Island surface waters are statistically different than Yellowknife River.
Copper	Horseshoe Island vs. Yellowknife River	No, the variances are equal	No, cannot reject the null hypothesis	Copper levels in Horseshoe Island surface waters are not statistically different than Yellowknife River.

Note: Antimony, manganese, sulphate, and zinc could not be included due to small sample sizes and/or datasets that did not have many detected samples.

The table indicates that concentrations of arsenic were statistically similar in Horseshoe Island and Yellowknife River. Concentrations of chloride were only slightly different in Horseshoe Island and Yellowknife River. It should be noted that the concentrations of chloride were higher at the Horseshoe Island location than the Yellowknife River location. Given the similarities between the three background locations, background concentrations were developed based on all locations combined (i.e., Prosperous Lake, Horseshoe Island, and Yellowknife River) (Table C.11). As seen from the table, there is only one measured sample for arsenic and thus a 95% UCLM value was not appropriate to calculate. It should be noted that all background concentrations were below available water quality guidelines.

Table C.11 Summary statistics for concentrations of COPCs in surface water from all background locations

COPC	Guideline	N	N < MDL	Water Concentration (mg/L) [d]						
				Min	Max	Mean	SD	Geomean	95th Percentile	95% UCLM
Antimony	-	19	18	2.5×10^{-5}	2.0×10^{-4}	1.6×10^{-4}	6.8×10^{-5}	1.4×10^{-4}	2.0×10^{-4}	NA
Arsenic	0.005[a]/ 0.01[b]	19	1	2.0×10^{-4}	0.0012	4.8×10^{-4}	2.1×10^{-4}	4.4×10^{-4}	8.0×10^{-4}	5.6×10^{-4}
Chloride	120[a]	19	0	1.6	6.4	3.5	1.9	3.01	6.2	5.4
Copper	0.002[a]	19	8	0.001	0.002	0.001	4.0×10^{-4}	8.1×10^{-4}	0.001	0.0011
Manganese	0.81[c]	19	12	0.001	0.0093	0.0024	0.0019	0.0020	0.0048	0.0035
Sulphate	218[c]	20	0	2.7	21	8.9	7.8	6.1	20	16
Zinc	0.03[a]	19	17	0.0015	0.011	0.0026	0.0022	0.0022	0.0061	0.0046

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean. No surface water guideline is available for this COPC.

a – CCME surface water quality guideline for the protection of freshwater aquatic life. Copper is based on a hardness of 47 mg/L (Yellowknife Bay).

b – Health Canada Drinking water guideline.

c – B.C. Aquatic guidelines based on hardness (47 mg/L for Yellowknife Bay).

d – Summary statistics for Min, Max, mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

C.3.1.2Summary

Table C.12 presents the summary of concentrations selected to represent background surface waters used in the ecological and human health risk assessment.

Table C.12 Summary of the selected concentrations for background surface water used in the ecological and human health risk assessment

COPC	N	Statistic	Background Concentration (mg/L)
Antimony	19	95th Percentile	2.0×10^{-4}
Arsenic	19	95% UCLM	5.6×10^{-4}
Chloride	19	95% UCLM	5.4
Copper	19	95% UCLM	0.0011
Manganese	19	95% UCLM	0.0035
Sulphate	20	95% UCLM	16
Zinc	19	95% UCLM	0.0046

Note: COPC = constituent of potential concern; N = sample size; 95% UCLM = 95th upper confidence level of the mean.

C.3.2 Establishing Baseline Surface Water Concentrations in Baker Creek

Due to the fact that there are inputs from the watershed upstream of the Giant Mine that influence concentrations in Baker Creek, baseline concentrations were developed to represent this condition.

The surface water quality station SNP 43-11 as well as surrounding stations in Upper Baker Creek (Reaches 7-11) were used for establishing baseline concentrations for ecological risk assessment in Baker Creek (Figure C.6). The reference site SNP 43-11 is located upstream of effluent discharge inputs from the Giant Mine and is historically used as reference station for downstream Baker Creek (Golder 2016b). There have been several surface water studies in recent years collected in reaches 7-11 (DCNJV 2014; Golder 2013, 2015a, 2015b, 2016c; Stantec 2014c). Appendix O provides concentrations for all the samples that were considered as baseline.

Antimony, arsenic, chloride and sulphate were all in exceedance of the applicable surface water guidelines in Baker Creek.

Table C.13 provides the summary statistics for COPC in surface water at baseline locations in Baker Creek.

Table C.13 Summary statistics for concentrations of COPCs in surface water from Baker Creek baseline locations

COPC	Guideline	N	N < MDL	Water Concentration (mg/L) [d]						
				Min	Max	Mean	SD	Geo Mean	95th Percentile	95% UCLM
Antimony	-	28	1	$7.0x10^{-4}$	0.30	0.01	0.06	$1.5x10^{-3}$	$5.0x10^{-3}$	$2.5x10^{-3}$
Arsenic	0.005[a]/ 0.01[b]	30	0	0.02	0.10	0.04	0.02	0.04	0.08	0.05
Chloride	120[a]	24	0	2.5	6.6	3.7	1.1	3.5	5.1	4.1
Copper	0.004[a]	30	9	$2.5x10^{-4}$	$6.8x10^{-3}$	$1.2x10^{-3}$	$1.3x10^{-3}$	$7.4x10^{-4}$	$2.9x10^{-3}$	$1.8x10^{-3}$
Cyanide	0.005[a]/0.2[b]	20	17	$5.0x10^{-4}$	$8.5x10^{-3}$	$2.7x10^{-3}$	$1.9x10^{-3}$	$2.2x10^{-3}$	$5.8x10^{-3}$	$6.3x10^{-3}$
Manganese	1.96[c]	28	0	$2.9x10^{-3}$	1.3	0.10	0.24	0.04	0.31	0.17
Sulphate	309[c]	24	0	2.2	72	13	17	7.4	47	28
Zinc	0.03[a]	30	19	$1.4x10^{-3}$	$7.9x10^{-3}$	$2.5x10^{-3}$	$1.5x10^{-3}$	$2.2x10^{-3}$	$4.6x10^{-3}$	$3.7x10^{-3}$

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean. No surface water guideline is available for this COPC

a – CCME surface water quality guideline for the protection of freshwater aquatic life. Copper based on hardness 80 mg/L for upper Baker Creek

b – Health Canada Drinking water guideline

c – B.C. Aquatic guidelines based on hardness (80 mg/L for upper Baker Creek)

d – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

Figure C.6 Baseline surface water sampling locations in Upper Baker Creek

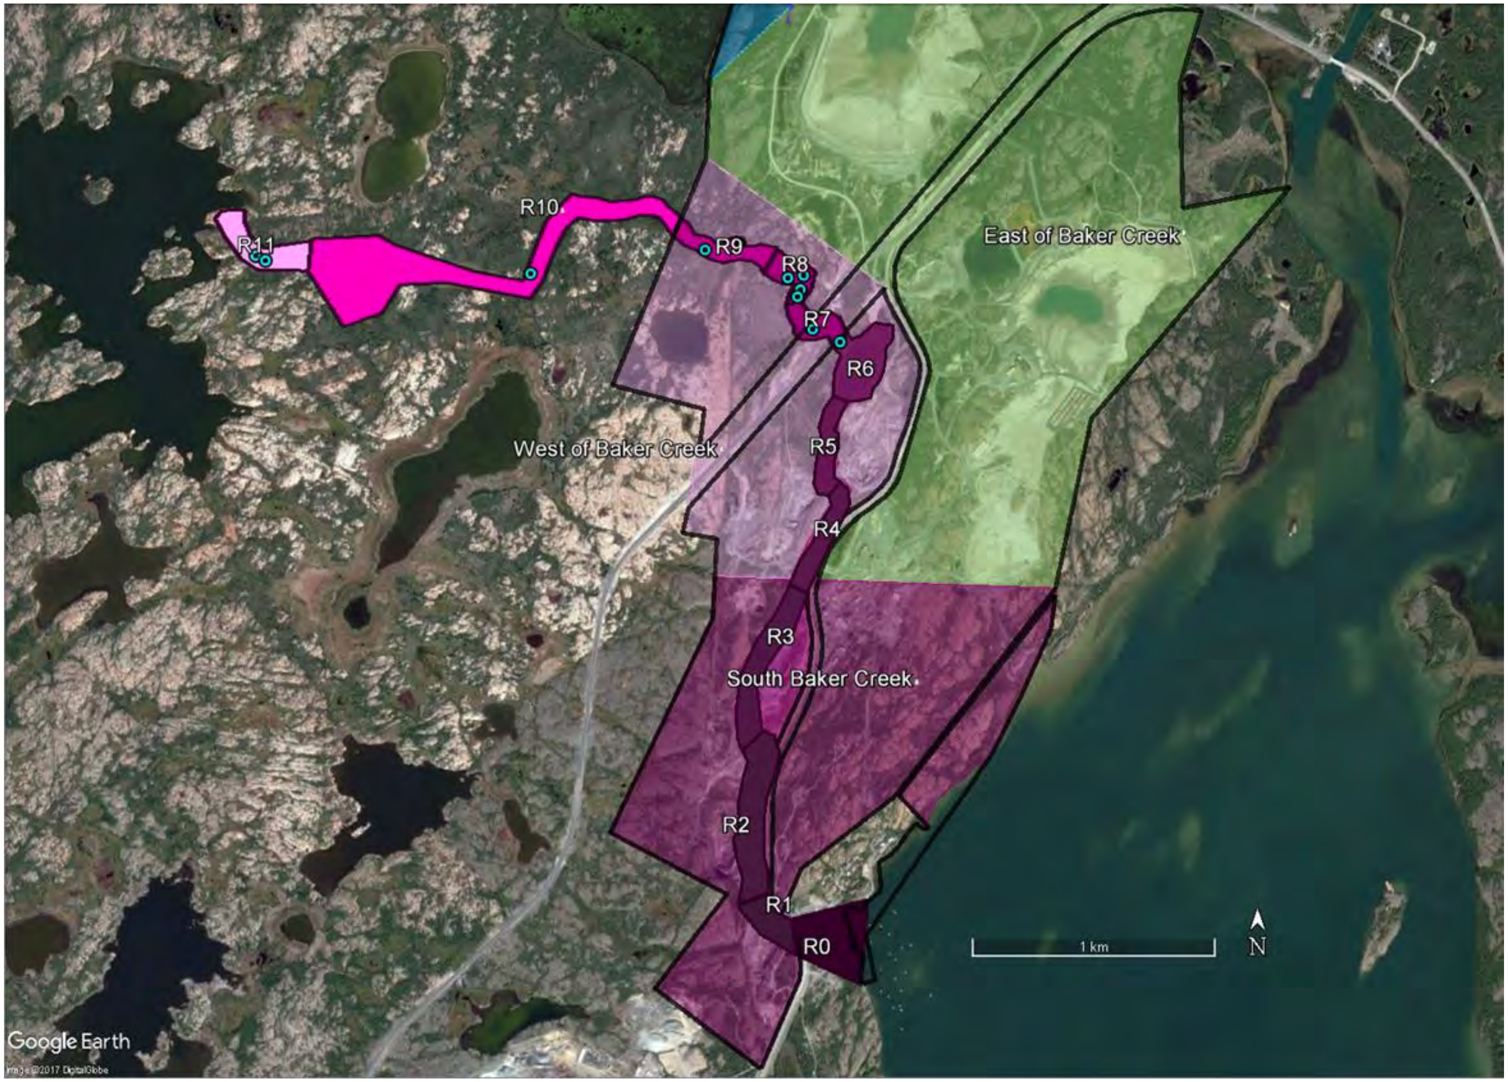


Table C.14 presents the summary of concentrations selected to represent baseline surface water in Baker Creek.

Table C.14 Summary of baseline surface water concentrations for Baker Creek

COPC	N	Statistic	Background Concentration (mg/L)
Antimony	28	95% UCLM	2.5×10^{-3}
Arsenic	30	95% UCLM	0.05
Chloride	24	95% UCLM	4.1
Copper	30	95% UCLM	1.8×10^{-3}
Cyanide	20	95% UCLM	6.3×10^{-3}
Manganese	28	95% UCLM	0.17
Sulphate	24	95% UCLM	28
Zinc	30	95% UCLM	3.7×10^{-3}

Note: COPC = constituent of potential concern; N = sample size; 95% UCLM = 95th upper confidence level of the mean.

C.4 Sediment Background Concentrations

There have been two sediment studies in recent years carried out at background locations (Golder 2013; Stantec 2014b) related to the Giant Mine Project. These background locations were used to develop sediment background and are Yellowknife River and Horseshoe Island located in South Yellowknife Bay (Figure C.7). A comparison of these background locations was conducted to determine whether they are similar.

The ecological COPCs for sediment include antimony, arsenic, chromium, copper, lead, manganese, mercury, and zinc. No screening guidelines have been developed to evaluate exposure of humans to contaminated sediments; therefore, the COPCs identified in the human health soil screening were considered to be the same for sediments. Background sediment concentrations were developed for antimony, arsenic, and manganese for the HHRA.

C.4.1 Development of Background Sediment Concentrations

In order to develop background sediment concentrations (95% UCLM), samples from recent years (e.g., 2011 to present) were used and considered to be representative of current conditions. Since the JoJo Tailings release occurred in May 2011 only data after this time were used in the assessment. Appendix O provides concentrations in all the samples that were considered as background.

The approach for developing sediment background for COPC was as follows:

- For estimating the 95% UCLM: The MDL was used (and identified as such) in the dataset used in ProUCL. ProUCL is a statistical program that provides 95% UCLM recommendations (based on data distribution, dataset size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate, in these cases, the highest appropriate 95% UCLM was selected.

C.4.1.1 Selection of Appropriate Dataset for Background Sediment Concentrations

A comparison of sediment samples from Horseshoe Island and sediment samples from Yellowknife River was conducted to ensure similarity between concentrations in a body of water and river and to evaluate their suitability for inclusion in background. Due to a small sample size for all COPC, a full statistical analysis could not be conducted reliably; therefore a simple comparison of summary statistics was used to determine if concentrations of COPC at Horseshoe Island and Yellowknife River were similar (Table C.15).

Table C.15 Summary statistics for background sediment concentrations of COPCs

COPC	Location	N	N<MDL	Sediment Concentration (mg/kg dw)[c]					
				Min	Max	Mean	SD	Geomean	95th Percentile
Antimony[a]	Horseshoe Island	5	0	1.0	1.1	1.0	0.1	1.0	1.1
	Yellowknife River	6	0	0.1	1.0	0.44	0.37	0.31	0.95
Arsenic[a,b]	Horseshoe Island	5	0	20	43	27	9.1	26	40
	Yellowknife River	6	0	2.5	10	6.4	2.6	5.9	9.6
Chromium[b]	Horseshoe Island	5	0	46	50	48	1.6	48	50
	Yellowknife River	6	0	16	41	27	12	25	41
Copper[b]	Horseshoe Island	5	0	38	44	40	2.1	40	43
	Yellowknife River	6	0	7.7	22	15	6.7	14	22
Manganese[a]	Horseshoe Island	5	0	448	627	516	71	512	606
	Yellowknife River	6	0	108	249	178	64	168	249

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean.

a – this is a human Health Soil COPC.

b – this is an ecological Sediment COPC identified in Yellowknife Bay.

c – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

Figure C.7 Background sediment sample locations

As seen from Table C.15, sediment COPC concentrations are higher around Horseshoe Island than in Yellowknife River.

From an ERA point of view, receptors were evaluated in both the lake and river environments and therefore the datasets were combined. From a human heath standpoint the combining of the datasets would result in a lower estimation of background concentrations and therefore represents a conservative estimate of background, especially for arsenic exposure which is evaluated incrementally (i.e., total minus background). Background concentrations for the combined locations (Horseshoe Island and Yellowknife River) are provided in Table C.16. As seen from the table, background concentrations for arsenic and chromium exceed sediment quality guidelines. There are no sediment quality guidelines for antimony and manganese.

Table C.16 Summary statistics for concentrations of COPCs in sediment from all background locations

Constituent	Guideline[c]	Background Concentration (mg/kg dw)[d]								
		N	N < MDL	Min	Max	Mean	SD	Geo Mean	95th Percentile	95% UCLM
Antimony[b]	-	11	0	0.1	1.1	0.7	0.4	0.5	1.1	1.2
Arsenic[ab]	5.9	11	0	2.5	43	16	13	12	35	23
Chromium[b]	37.3	11	0	16	50	36.8	14	34	50	44
Copper[a]	35.7	11	0	7.7	44	26	14	22	42	34
Manganese[b]	-	11	0	19	168	86	59	66	163	434

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean.

- no ecological sediment guideline is available for this COPC.

a – this is an Ecological Sediment COPC.

b – this is a Human Health Sediment COPC.

c – CCME sediment guideline for protection of aquatic life Interim Sediment Quality Guideline (ISQG).

d – Summary statistics for Min, Max, Mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

For the evaluation of benthic organisms in Back Bay, the average sediment concentrations of the samples from Horseshoe Island were used. It should be noted that the average concentrations from Horseshoe Island are similar to the 95% UCLM values from the combined dataset of river and bay.

C.4.1.2 Summary

In general, concentrations of COPC in South Yellowknife Bay and Yellowknife River were similar. Therefore, all background locations were combined to determine the background concentrations used in the HHERA (Table C.17).

Table C.17 Summary of the background sediment concentrations for combined river and bay locations

COPC	N	Statistic	Background Sediment Concentration (mg/kg dw)
Antimony	11	95% UCLM	1.2
Arsenic	11	95% UCLM	23
Chromium	11	95% UCLM	44
Copper	11	95% UCLM	34
Manganese	11	95% UCLM	434

Note: COPC = constituent of potential concern; N = sample size; 95% UCLM = 95th upper confidence level of the mean.

Table C.18 Summary of the background sediment concentrations for Yellowknife Bay

COPC	N	Statistic	Background Sediment Concentration (mg/kg dw)
Antimony	5	Average	1.0
Arsenic	5	Average	27
Chromium	5	Average	48
Copper	5	Average	40
Manganese	5	Average	516

Note: COPC = constituent of potential concern; N = sample size; 95% UCLM = 95th upper confidence level of the mean.
This Table only used for weight of evidence for benthic organisms in Back Bay

C.4.2 Establishing Baseline Sediment Concentrations in Baker Creek

The sediment samples obtained within proximity to the surface water reference station SNP 43-11 in Reaches 7 to 11 was used for establishing baseline concentrations in Baker Creek (Figure C.8). The reference location is upstream of effluent discharge inputs from the Giant Mine and is historically used as reference station for downstream Baker Creek (Golder 2016b). There have been four sediment studies collecting data in Reaches 7 to 11

(Golder 2013, 2015a, 2016d; Stantec 2014c). Appendix O provides concentrations for all the samples that were considered as baseline.

Antimony, arsenic, chromium, lead, mercury, and zinc were identified as ecological COPC in sediments in Baker Creek. Table C.19 provides summary statistics for baseline sediment samples in Baker Creek. As seen from Table C.19, baseline sediment concentrations of arsenic and chromium are above the CCME sediment quality guidelines.

Table C.20 provides a summary of the baseline sediment concentrations in Baker Creek.

Figure C.8 Baseline sediment sampling locations in Baker Creek

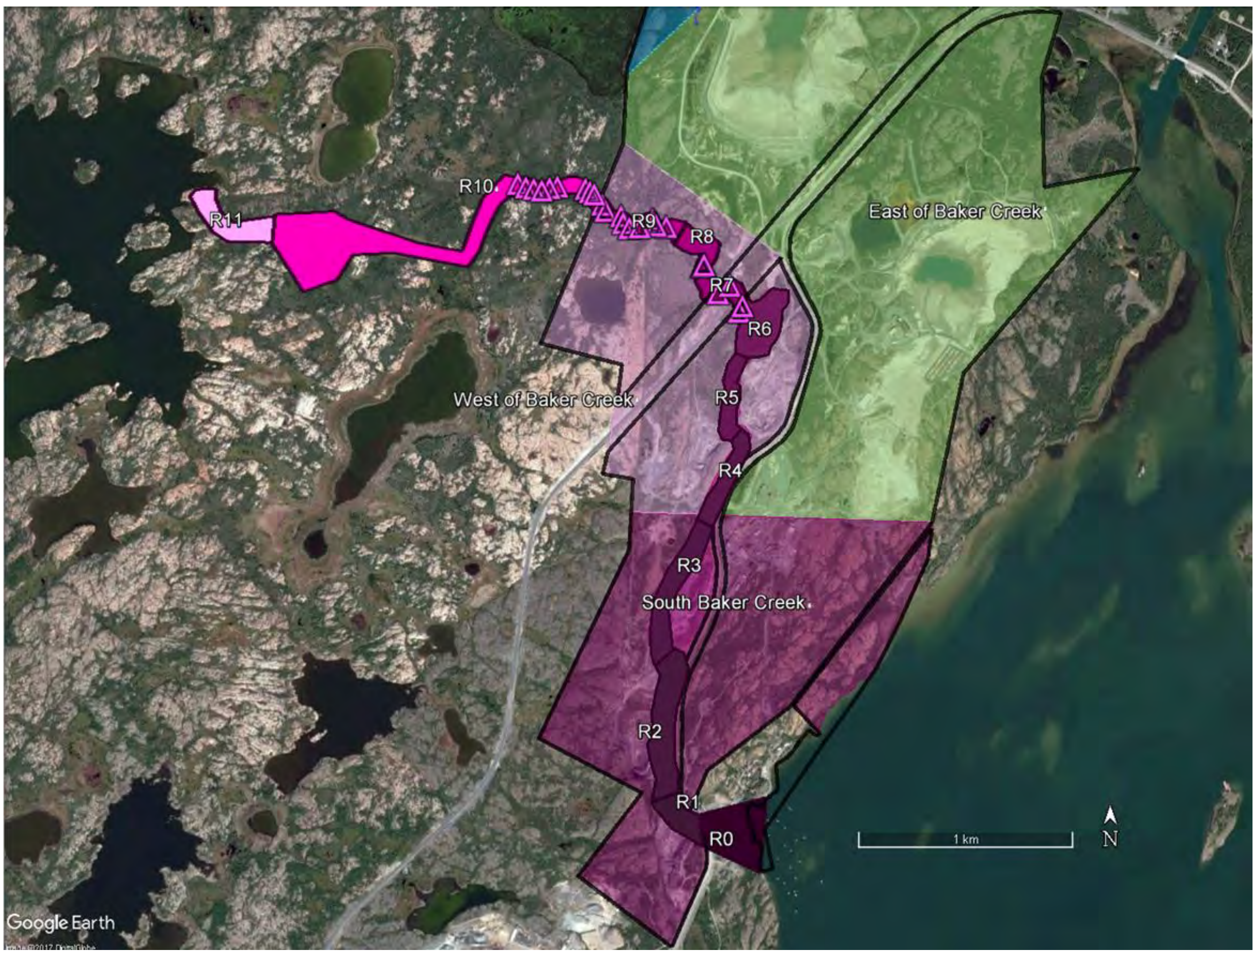

Table C.19 Summary statistics for concentrations of COPCs in sediment from baseline locations in Upper Baker Creek

COPC	Guideline[a]	N	N< MDL	Sediment Concentration (mg/kg dw)[b]						
				Min	Max	Mean	SD	GeoMean	95th Percentile	95% UCLM
Antimony	-	27	0	0	12	4.1	3	3.0	10	5.0
Arsenic	5.9	27	0	16	440	152	96	119	294	183
Chromium	37.3	28	0	21	135	33	23	30	69	41
Lead	35	27	1	2.5	11	5.9	2.0	5.6	9.2	6.7
Mercury	0.17	27	2	0.01	0.13	0.03	0.03	0.03	0.08	0.05
Zinc	123	36	0	0	486	49	77	25	79	42

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95^{th} upper confidence level of the mean.

a – CCME sediment guideline for protection of aquatic life Interim Sediment Quality Guideline (ISQG).

b – Summary statistics for Min, Max, Mean, SD, Geomean, and 95^{th} percentile were calculated using one half the method detection limit.

Table C.20 Summary of baseline sediments concentrations in Baker Creek

COPC	Statistic	Background Sediment Concentration (mg/kg dw)
Antimony	95% UCLM	5
Arsenic	95% UCLM	183
Chromium	95% UCLM	41
Lead	95% UCLM	6.7
Mercury	95% UCLM	0.05
Zinc	95% UCLM	42

Note: COPC = constituent of potential concern; N = sample size; 95% UCLM = 95th upper confidence level of the mean.

C.5 Background Food Concentrations for the Human Health Risk Assessment

Background country food concentrations associated with samples from the country food study were discussed in the main document. This section focuses on background fish samples and mushroom samples that were collected from other scientific studies. Background fish and mushroom concentrations were developed for antimony, arsenic and manganese which were the three COPC identified for a quantitative evaluation in the HHRA.

C.5.1 Fish Muscle Background Concentrations

Background fish muscle samples were collected from two studies in 2010 and 2011 (Cott et al. 2016; Stantec 2014d). Fish muscle samples for consumable fish were obtained from Horseshoe Island, MacKenzie Island, and Great Slave Lake and are summarized in Table C.21. Appendix O provides concentrations in all the samples that were considered as background.

As seen from Table C.21, data were sufficient to calculate a 95% UCLM for arsenic in inconnu, lake whitefish, and northern pike, and for manganese in lake whitefish. In the absence of a 95% UCLM, the 95th percentile was selected to represent background fish concentrations for antimony and manganese. This represents a conservative estimate of fish background. Background concentrations are summarized in Table C.22.

Table C.21 Summary of background concentrations in consumable fish muscle

Fish Species	COPC	N	N < MDL	Fish Muscle Concentration (mg/kg ww)[a]						
				Min	Max	Mean	SD	Geomean	95th Percentile	95% UCLM
Inconnu	Antimony	47	44	0.025	0.12	0.028	0.015	0.027	0.042	NA
	Arsenic	47	0	0.08	0.56	0.182	0.078	0.170	0.274	0.201
	Manganese	47	47	0.15	0.15	NA	NA	NA	NA	NA
Lake Whitefish	Antimony	38	37	0.0005	0.025	0.016	0.010	0.011	0.025	NA
	Arsenic	38	1	0.025	0.641	0.150	0.120	0.117	0.321	0.235
	Manganese	38	21	0.111	1.44	0.223	0.226	0.185	0.506	0.262
Northern Pike	Antimony	41	41	0.025	0.025	NA	NA	NA	NA	NA
	Arsenic	41	0	0.06	0.22	0.105	0.036	0.100	0.170	0.115
	Manganese	41	41	0.15	0.15	NA	NA	NA	NA	NA

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean.
a – Summary statistics for Min, Max, mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit.

Table C.22 Summary of selected background concentrations for consumable fish muscle

Fish Species	COPC	Statistic	Background Fish Concentration (mg/kg ww)
Inconnu	Antimony	95th Percentile	0.042
	Arsenic	95% UCLM	0.201
	Manganese	Maximum	0.15
Lake Whitefish	Antimony	95th Percentile	0.025
	Arsenic	95% UCLM	0.235
	Manganese	95% UCLM	0.26
Northern Pike	Antimony	Maximum	0.025
	Arsenic	95% UCLM	0.115
	Manganese	Maximum	0.15

C.5.2 Mushroom Background Concentrations

All of the data used to determine background mushroom concentrations were obtained from a study conducted by Obst (2014). Mushroom sample locations from more than 50 km away from the Giant Mine, were selected to represent background. Table C.23 presents the summary statistics for background mushroom concentrations. Appendix O provides concentrations in all the samples that were considered as background. As seen from Table C.23, data were sufficient to calculate a 95% UCLM for antimony, arsenic, and manganese, which were selected as the background mushroom concentrations in the HHRA.

Table C.23 Summary statistics for concentration of COPCs in mushrooms from background locations

COPC	N	N<MDL	Mushroom Concentrations (mg/kg ww)[a]						
			Min	Max	Average	SD	GeoMean	95th Percentile	95% UCLM
Antimony	58	32	0.0075	0.20	0.033	0.045	0.017	0.14	**0.062**
Arsenic	58	25	0.015	15	0.6	2.3	0.09	3.3	**2.0**
Manganese	58	0	0.27	0.27	4.6	4.9	2.6	16	**5.8**

Note: COPC = constituent of potential concern; N = sample size; N<MDL = number of samples less than the method detection limit; NA = not applicable – this statistic could not be calculated due to insufficient data; SD = standard deviation of the mean; Geomean = geometric mean; 95% UCLM = 95th upper confidence level of the mean.

a – Summary statistics for Min, Max, mean, SD, Geomean, and 95th percentile were calculated using one half the method detection limit. **Bold** values selected as background concentrations for the HHRA.

APPENDIX D

SELECTION OF CONSTITUENTS OF POTENTIAL CONCERN

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX D: SELECTION OF CONSTITUENTS OF POTENTIAL CONCERN

D.1 Overview

A tiered process was carried out to identify constituents of potential concern (COPC) in surface water, soil, and sediment in the general vicinity of Yellowknife and the Giant Mine and involved an evaluation of measured environmental data. The general tiered approach that was followed for the COPC selection process, based on measured water and soil concentrations, is illustrated in Figure D.1 (a different approach was followed for the sediment screen, as detailed in Section D.4) and is described below. More details on the screening for each of the media are provided in the following sections. In general, the steps in the screening process were:

1. If 90% or more of the measurements for a constituent were non-detectable (i.e., below the method detection limit [MDL]), then the data were considered to be essentially not measured and the constituent was dropped from further assessment. The treatment of MDLs is discussed in the various sections below.

2. The maximum (or 95th percentile, where there were more than 90 samples) measured concentrations were then compared to the appropriate screening criteria (as discussed below). Constituents with concentrations lower than the screening criteria were dropped from further assessment, while those with concentrations exceeding the screening criteria, or with no criteria available, were carried forward to Step 3.

3. The maximum (or 95th percentile, where there were more than 90 samples) measured concentrations were compared to average background concentrations as discussed in more detail below. ATTACHMENT D.1 discusses background concentrations. If the measured concentration was below the background average, then the constituent was considered to be present at background levels and was not considered to be a COPC. This preliminary comparison to background is meant to provide a general indication of differences to eliminate the need for detailed statistical test on every parameter. Comparison to background is explored more rigorously in a subsequent stage.

4. Constituents remaining as potential COPC after steps 1 through 3 were then checked to see if corresponding human health and/or ecological toxicity data were available. Constituents with available toxicity data were selected as COPC, while

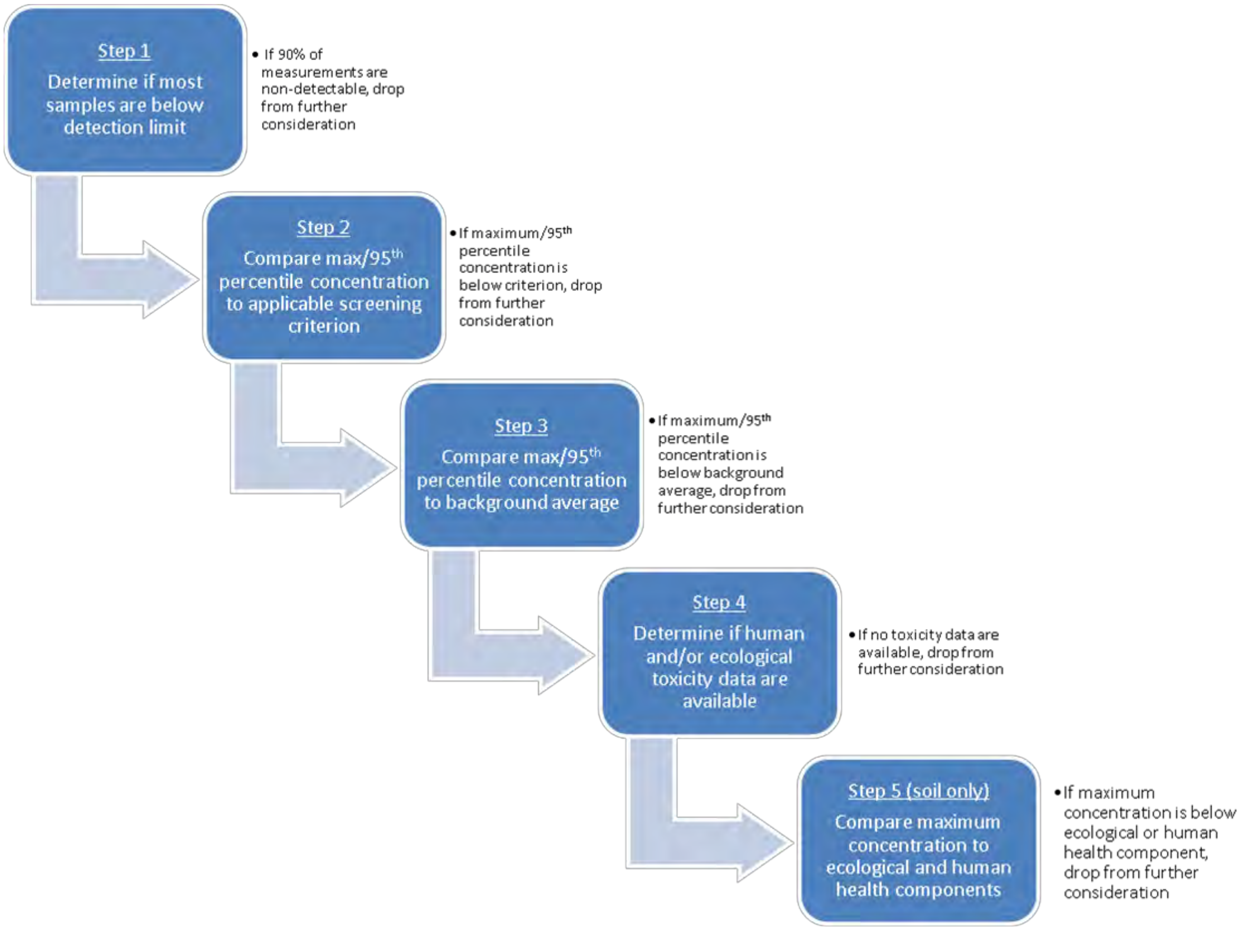
those without toxicity data were not further assessed. Although this adds some uncertainty to the assessment, the lack of toxicity data generally denotes constituents that cannot be evaluated quantitatively.

5. For the soil screen, the final step involved determining which constituents would be evaluated in the human health risk assessment (HHRA) and the ecological risk assessment (ERA). This was already completed in Step 2 for surface water as separate guidelines specific to human and ecological protection were considered. For soil, given that there were more than 90 samples, the 95th percentile measured concentrations of remaining constituents were then compared to the most restrictive of the human health and ecological components of the appropriate screening criteria in order to identify those COPC for further consideration in the HHRA and ERA, respectively.

Values below the MDL were converted to ½ the MDL before calculating summary statistics (e.g., average, 95th percentile, and standard deviation) for the COPC screen. This approach was only used for the screening step. In the risk assessment, the detection limits were handled within the ProUCL program and no adjustments were made.

Antweiler (2015) and Ogden (2010) indicate that, for datasets with a low degree of censoring (i.e., less than 25% of measurements below the MDL) and a total number of observations between 20 and 100, the substitution of non-detects with a value of ½ the MDL shows "fairly modest bias in the 95th percentile or the mean, and the imprecisions of these estimates are only slightly worse than the optimum method of data treatment" (Ogden 2010). This approach was adopted for data analysis at the screening stage. Given that for some constituents there were a high number of MDLs in the considered dataset, additional examination of both the soil and surface water datasets was conducted to ensure that the MDLs were handled appropriately. This is discussed in more detail in the applicable sections below. In addition, a sensitivity analysis was carried out to investigate the effect of different methods of data treatment for non-detect values (i.e., <MDL). For soil, this analysis involved looking at many of the common substitutions that are present in the literature (i.e., 0, ½ MDL, $1/\sqrt{(2)}$ MDL, MDL). It should be noted that a substitution of 0 or the MDL itself are the extreme bounds on the possible true value of the soil concentration. The sensitivity analysis is detailed in ATTACHMENT D.2.

Figure D.1 General selection process for constituents of potential concern



D.2 Constituents of Potential Concern in Soil

The soil COPC screen considered measured soil concentrations from across the Yellowknife area. As soil concentrations generally change slowly over time, all compiled data (from 1999 and onwards) were considered for the Yellowknife area. This ensures that both off-site and on-site conditions at the Giant Mine are considered. Analytical data has demonstrated that constituent concentrations are generally higher in surficial soils; in addition, this soil depth represents the likely exposure depth for both humans and animals. Although preference was given to data from the upper five centimeters (5 cm) profile, it should be noted that concentrations at a depth of ≤ 10 cm were considered for the soil screening process as some of the constituents were not measured at the 5 cm depth. There were different MDLs in some of the data sets and the treatment of the different MDLs is discussed in more detail below. All the datasets were considered equally as metal concentrations in soil do not decrease over time.

For the soil COPC screen, the agricultural soil guidelines from the Canadian Council of Ministers of the Environment (CCME 2017) were considered appropriate. The use of the most restrictive agricultural criteria ensures that all potential COPC are captured in the screening process. In the absence of CCME guideline values, the generic site condition standards for coarse textured soil and agricultural land use in a potable water scenario from the Ontario Ministry of the Environment and Climate Change (formerly Ontario Ministry of the Environment [MOE 2011])) were used. For this application, boron was the only constituent where the MOE soil guideline was used. The criterion is based on ecological considerations and is considered to be appropriate for this application.

A summary of the screening process for COPC in soil is provided in Figure D.2, while details on each step of the process are provided in this section. Summary statistics of the considered data are presented below in Table D.1 along with the soil COPC screen details.

Figure D.2 Flowchart of soil constituents of potential concern screening results

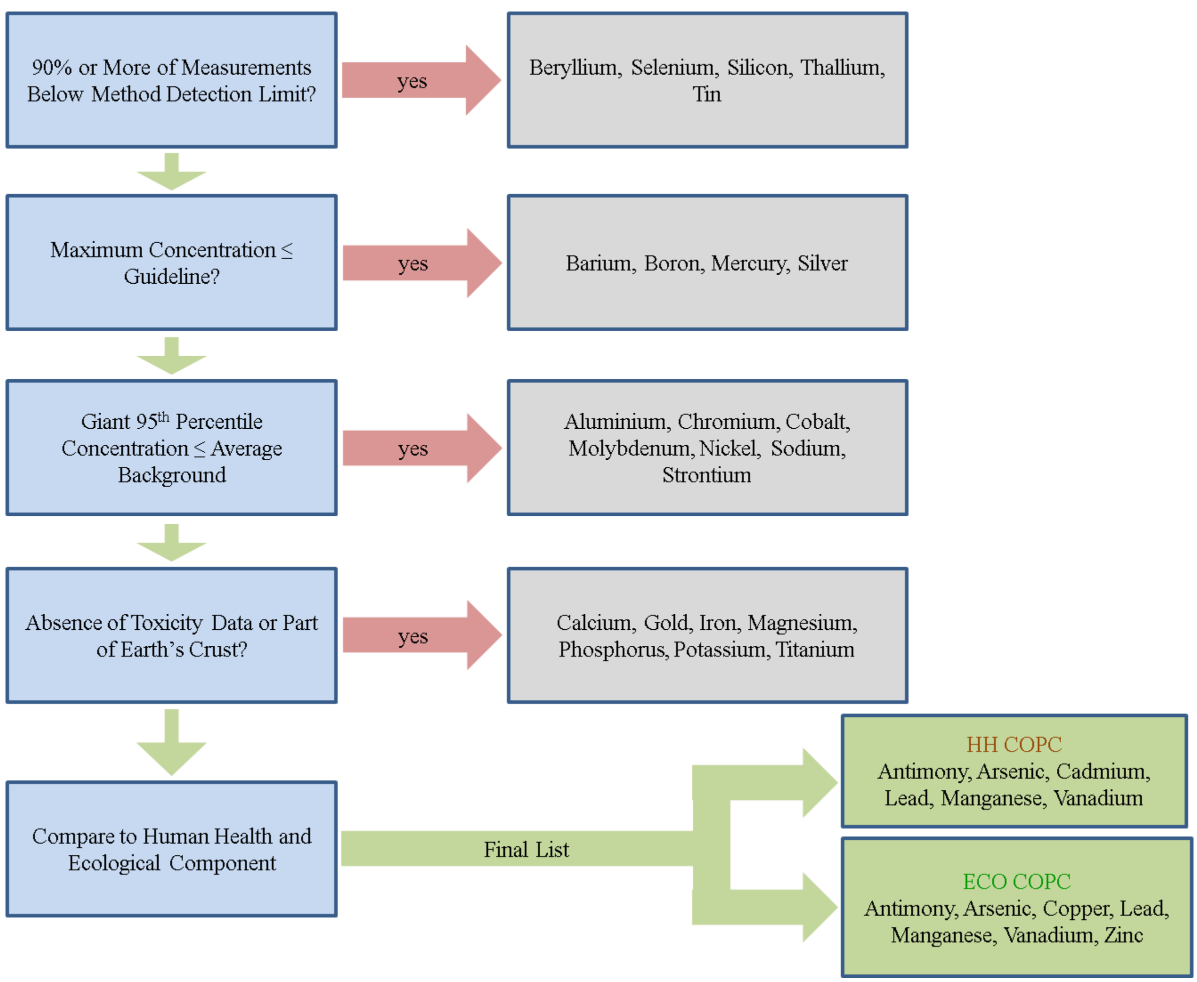


Table D.1 Selection of constituents of potential concern in soil for the risk assessment

Constituent	Unit	Soil Guideline [a]	Bkgd Avg	Yellowknife Area						Giant Mine	Heavily Censored? (90% or more < MDL)	Max ≤ Guideline?	Giant Mine 95th Percentile ≤ Bkgd Avg?	Lack of Tox Data or Part of Earth's Crust?	COPC out of Step 4?	Rationale

Zinc	mg/kg	200	93	280	2	7.1	800	134	122	354	N	N	N	-	Y	Maximum Measured Value > Guideline, Giant Mine 95th Percentile > Avg Bkgd, Toxicity Data Available.

Note: a – Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline, supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline if CCME value unavailable; b – Based on a student's t-test assuming unequal variances and an alpha of 0.05. The criterion for boron is from the MOE (2011).

Table D.1 Selection of constituents of potential concern in soil for the risk assessment (Cont'd)

COPC	COPC from Step 4?	Unit	Human Health Component (a)	Ecological Component (a)	Giant Mine 95th Percentile	HH COPC?	Rationale	Eco COPC?	Rationale
Antimony	Y	mg/kg	7.5	20	371	Y	Giant Site 95th Percentile > HH Component	Y	Giant Mine 95th Percentile > Eco Component.
Arsenic	Y	mg/kg	12	17	5046	Y	Giant Site 95th Percentile > HH Component	Y	Giant Mine 95th Percentile > Eco Component.
Cadmium	Y	mg/kg	1.4	3.8	2.1	Y	Giant Site 95th Percentile > HH Component	N	Giant Mine 95th Percentile ≤ Eco Component.
Copper	Y	mg/kg	1100	63	201	N	Giant Site 95th Percentile ≤ HH Component	Y	Giant Mine 95th Percentile > Eco Component.
Lead	Y	mg/kg	140	70	230	Y	Giant Site 95th Percentile > HH Component	Y	Giant Mine 95th Percentile > Eco Component.
Manganese	Y	mg/kg	-	-	3594	Y	No HH Component, Toxicity Data Available	Y	No Eco Component, Toxicity Data Available.
Uranium	Y	mg/kg	23	33	18	N	Giant Site 95th Percentile ≤ HH Component	N	Giant Mine 95th Percentile ≤ Eco Component.
Vanadium	Y	mg/kg	39	130	132	Y	Giant Site 95th Percentile > HH Component	Y	Giant Mine 95th Percentile > Eco Component.
Zinc	Y	mg/kg	5600	200	354	N	Giant Site 95th Percentile ≤ HH Component	Y	Giant Mine 95th Percentile > Eco Component.

Note: a – Human health and ecological components of the Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline, supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline components if CCME value unavailable. The component values for antimony, vanadium and zinc are from the MOE (2011). These values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.

Following the screening procedure outlined in Figure D.1, the first step of the soil COPC screen identified constituents with the majority of data points below the MDL. As shown in Figure D.2 and Table D.1, a large percentage (more than 90%) of the measurements were below the MDL for beryllium, selenium, silicon, thallium and tin and thus they were dropped from further assessment. ATTACHMENT D.2 provides a discussion of detection limits and indicates the reasons for dropping these constituents. As the reported MDLs vary from study to study, the detection limits were examined in detail as discussed in ATTACHMENT D.2 to ensure constituents were not dropped erroneously due to the presence of elevated MDLs in either the background or non-background datasets.

Given that selenium is an important micronutrient from a human health standpoint, the COPC screen included additional examination of the analytical data for selenium in soil. In addition to more than 90% of the samples (219 out of 244 samples) being below the MDL, all of the MDLs are well below both the CCME (2017) human health component value (80 mg/kg) and the MOE (2011) Table 2 human health value (78 mg/kg), supporting the decision to drop selenium as a COPC in soil.

For beryllium, 219 out of 229 samples were below the MDL and the maximum concentration, as shown in Table D.1, is 2 mg/kg which is below the guideline. A similar rationale was used for tin where 219 out of 224 samples are below the MDL and the maximum concentration is below the guideline. For silicon, all the samples are below the MDL and thus silicon was not considered to be measured. For thallium, 203 out of 224 samples are below the MDL. A comparison was done for the reported MDLs to the (2017) soil guideline and all of the MDLs were at or below this guideline. This discussion confirms that these constituents should be dropped in Step 1. ATTACHMENT D.2 discusses the method detection limits.

The second step involved comparison of maximum measured levels from the Yellowknife area to the appropriate screening criteria. As indicated in Figure D.2, barium, boron, mercury, and silver were dropped from consideration as all measured levels from the Yellowknife area were below the applicable guideline. In the early days of operation of the Giant Mine, mercury and cyanide amalgamation was used before the roaster was brought online. ATTACHMENT D.3 provides a discussion of mercury in various media around the Giant Mine and concludes that it is not a COPC from a human health standpoint. A few sediment samples had mercury concentrations above the sediment quality guideline, thus mercury was included as a COPC in sediment for the ERA.

It should be noted that the highest measured concentrations all occurred at the Giant Mine and in all the further screening steps only data from the Giant Mine were considered.

The next step involved comparing measured data to background concentrations to determine which constituents are elevated above natural levels. The soil COPC screen included consideration of all background data, regardless of sampling location or depth, as it is more representative of the regional background conditions. The Federal Contaminated Sites Action Plan (FCSAP 2015) background document refers to United States Environmental Protection Agency (U.S. EPA 2002) guidance for developing an appropriate background concentration. This guidance uses an average concentration for background when comparing to exposure areas to determine the difference between background and exposure areas. This approach was used for the COPC screen. Further details on the development of background concentrations for the COPC screen are provided in ATTACHMENT D.1.

Average background concentrations used in the soil COPC screen were calculated from data reported in three studies (Stantec 2014a; Stevens et al. 2015; Golder 2016), as well as till data collected in 1999, 2000, and 2001 by Daniel Kerr and compiled in the Geological Survey of Canada (GSC) database[1]; the majority of the considered background data were obtained from the GSC database. All values below the MDL were converted to ½ the MDL before the average values were calculated. As discussed previously, Antweiler (2015) and Ogden (2010) indicate that for low degrees of censoring (<25%) and the number of observations between 20 and 100 that the substitution of ½ the MDL shows "fairly modest bias in the 95th percentile or the mean, and the imprecisions of these estimates are only slightly worse than the optimum method of data treatment".

As there is a large set of data from the Giant Mine (greater than 200 samples for most constituents), the 95th percentiles of the Giant Mine data were compared to the average background concentrations. This is considered to be a reasonably conservative approach for omitting anomalous measurements related to the Giant Mine.

This step resulted in the removal of aluminum, chromium, sodium, and strontium since the 95th percentile concentrations were below the background averages. It should be noted that the maximum concentrations of aluminum, sodium and strontium were also

[1] Data available for download from http://geochem.nrcan.gc.ca/cdogs/content/svy/svy210026_e.htm

below the background concentrations and only 6 of 224 samples (2.7%) for chromium are above the average concentration; therefore the removal of these constituents is valid. Additional analysis (student t-test, alpha = 0.05) and a graphical representation of the Giant Mine and regional background data showed that there is no statistically significant difference between the Giant Mine data and background distributions for cobalt, molybdenum, and nickel; thus, these constituents were not considered further in the assessment. The selected student t-test takes into account any difference in variance between the two data sets and is appropriate for use with data sets of unequal sample sizes which is the case for this application where there are over 200 samples collected at the Giant Mine and approximately 120 background samples. Frequency distribution plots comparing the background and Giant Mine measured data are shown in Figure D.3 for a number of constituents. In these plots the individual background concentrations and the individual samples from the Giant Mine were binned into concentration ranges. The plots for cobalt, molybdenum, and nickel corroborate the findings of the statistical test and show that the Giant Mine data and the background data are similarly distributed while the plots for other constituents (particularly antimony, arsenic, and lead) show greater difference between Giant Mine and background data.

Of the remaining constituents, regulatory screening criteria were not available for calcium, gold, iron, magnesium, manganese, phosphorus, potassium, and titanium. Of these, gold and titanium were dropped from further assessment due to lack of human health and ecological toxicological data. Additionally, calcium, iron, magnesium, phosphorus, and potassium are considered as natural elements in the earth's crust and are therefore not COPC. The following discussion supports the exclusion of a number of these constituents:

- Calcium: The technical supporting document for the drinking water guideline development for calcium by Health Canada (1987a) states that because of the efficient homeostatic mechanisms that control calcium metabolism, adverse effects are observed only following the intake of extremely large quantities of calcium. Thus calcium is not considered further. It should be noted that Health Canada has not updated this document recently.
- Iron: Health Canada (1987b) notes that there is no evidence of dietary iron toxicity in the general population. It should be noted that Health Canada has not updated this document recently. In addition, the National Research Council (NRC 2005) state that there are inadequate data available to accurately define maximum

tolerable levels of iron from dietary or water sources for most non-laboratory animals. Very few studies have included incremental dose levels sufficient to determine thresholds for toxicity. However, maximum tolerable levels of iron have been determined for cattle, sheep, and poultry (500 mg/kg), as well as swine (3,000 mg/kg). Other reported toxic iron levels are greater than 4,000 mg/kg for cattle and 390 mg/kg for horses (Puls 1994). Iron toxicosis can occur in domesticated animals as they are often given dietary supplements. It is expected that most animals do not uptake large amounts of iron in their diet (NRC 2005) and it is not anticipated that iron will have the potential to cause adverse effects to humans or terrestrial biotic receptors at the Giant Mine.

- Magnesium: Magnesium is an essential element in human metabolism and is required for over 300 enzyme reactions. The most readily observable adverse effect of magnesium in drinking water is the laxative effect (Health Canada 1987c). Thus magnesium is not considered further. It should be noted that Health Canada has not updated this document recently.
- Phosphorus: Phosphorus is an essential nutrient required for critical biological reactions that maintain the normal homoeostatic control of the cell. The CCME (2013) has confirmed that phosphorus does not pose a direct threat to human health; it is an essential component of all cells and is present in bones and teeth. The issue with phosphorus is as a nutrient that can affect water quality.
- Potassium: Potassium is an essential element that helps regulate fluid volumes in cells and is thus necessary to maintain normal cell function. Potassium also acts to blunt the risk of blood pressure in response to sodium and decreases markers of bone turnover and recurrence of kidney stones (Institute of Medicine [IOM 2005]). There are no health effects noted from excessive consumption of potassium in food (IOM 2005) and thus the IOM did not derive an upper limit (maximum level of daily nutrient that is likely to pose no risk of health effects).

Zinc Soil Concentration (mg/kg)

The fifth and final step of the screen compared the 95th percentile concentrations from the Giant Mine to the most restrictive of the ecological and human health components of the appropriate screening criteria in order to identify those COPC for further consideration in the ERA and HHRA, respectively. Most of the component values were obtained from the CCME (2017); however, the component values for antimony, vanadium and zinc were obtained from the MOE (2011); these values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.

This essentially represents a qualitative screening level risk assessment. Uranium was removed from consideration as the 95th percentile concentration at the Giant Mine was below both the ecological and human health components. There is no screening criterion, and hence no ecological or human health components, available for manganese, toxicity data are available and therefore it was selected as a COPC for both the ERA and HHRA.

As shown in Figure D.2, the remaining constituents retained as COPC include: antimony, arsenic, cadmium, copper, lead, manganese, vanadium, and zinc. Of these COPC, copper, and zinc were not carried forward for the HHRA since the 95th percentile of measured concentrations at the Giant Mine were below the human health components. Cadmium was not retained as a COPC for the ERA as the 95th percentile of measured concentrations at the Giant Mine was below the ecological component value.

A sensitivity analysis was carried out to investigate the effect of different methods of data treatment for non-detect values (i.e., <MDL). For soil, this analysis involved looking at many of the common substitutions that are present in the literature (i.e., 0, ½ MDL, 1/√(2) MDL, MDL). It should be noted that a substitution of 0 or the MDL itself are the extreme bounds on the possible true value of the soil concentration. The sensitivity test found that none of these substitutions changed the final soil COPC list, as detailed in ATTACHMENT D.2.

D.3 Constituents of Potential Concern in Surface Water

The surface water COPC screen was completed to identify COPC in Yellowknife Bay for human receptors (i.e., for the HHRA) that may use this water body as a drinking water source directly (i.e., not municipally treated and distributed), and to identify COPC in both Baker Creek and Yellowknife Bay for aquatic biota (i.e., for the ERA). Data for total metals collected from June 2011 onwards were considered in the process to represent current conditions as these data were collected after the JoJo tailings spill.

For Baker Creek, data from all reaches downstream of Baker Pond were included, as well as data collected from Back Bay at the outlet of Baker Creek (i.e., Station S18 that was sampled in 2012 and 2013 [Stantec 2014b]). For Yellowknife Bay, data from all areas were considered, including Back Bay (with the exception of S18), North Yellowknife Bay (i.e., around Latham Island and Ndilo), and South Yellowknife Bay (i.e., east of Yellowknife and around Dettah). Due to the large number of measurements available for each location, the 95th percentile concentrations of the measured data were used in the screening process. As discussed above, this is considered to be a reasonably conservative approach for omitting anomalous measurements.

For the HHRA, the Health Canada (2017) Guidelines for Canadian Drinking Water Quality were selected preferentially as the screening criteria. It should be noted that Health Canada considers that water with concentrations of constituents below these values is safe to drink. The risk-based values for drinking water for arsenic are based on the as low as reasonably achievable (ALARA) principle. In instances where the guideline for a constituent was based on an aesthetic objective (AO) or operational guideline (OG) and not a health-based maximum acceptable concentration (MAC), other sources of health-based drinking water guidelines were consulted including the British Columbia Ministry of Environment (BCMOE 2010) for aluminum, iron and manganese, and the U.S. EPA (2016a) Regional Screening Levels (RSLs) for tap water. To be consistent with the Giant Mine Problem Formulation (Stantec 2015) and Canadian guideline derivation procedures, the RSLs were adjusted for a target hazard quotient (THQ) value of 0.2 (i.e., RSL for a THQ of 1, divided by 5) for non-carcinogenic constituents.

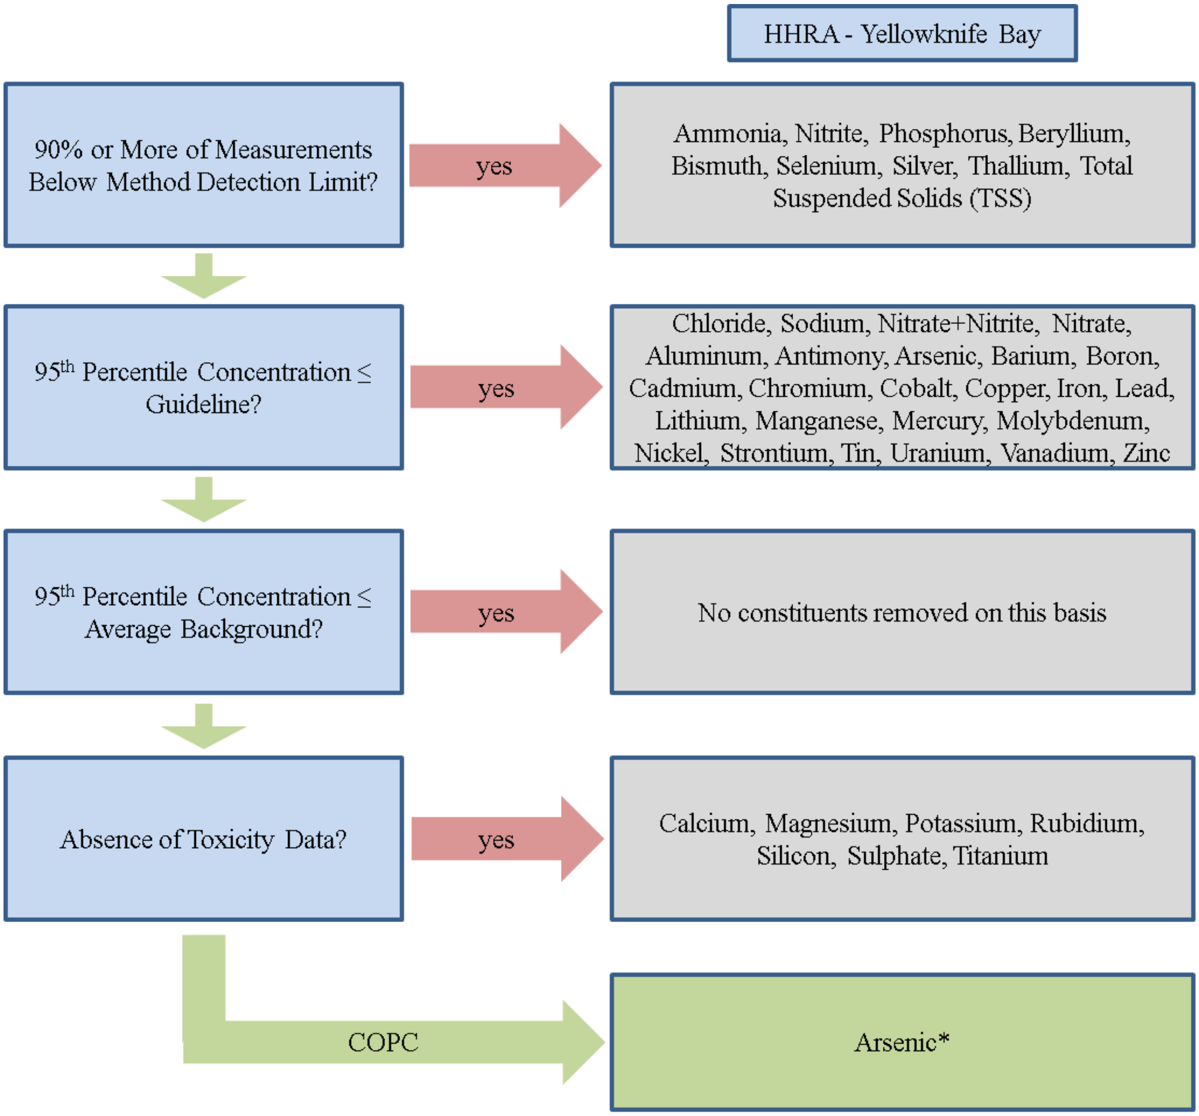
For selecting COPC for the ERA, surface water quality guidelines for the protection of freshwater aquatic life for long-term exposure from the CCME (2017) were considered. In the absence of a value from the CCME, other sources were consulted such as the Saskatchewan Environmental Quality Guidelines (SEQG; Government of Saskatchewan (GS 2015)), U.S. EPA (2016b) Water Quality Benchmarks for Aquatic Life, and the BCMOE (2017) Water Quality Guidelines to Protect Aquatic Life.

For guidelines that vary with hardness (i.e., copper, lead, manganese, and nickel), the average hardness of the 2010 to 2015 measurements for that particular waterbody (i.e., 46.8 mg/L for Yellowknife Bay and 394 mg/L for Baker Creek) was used to set the guideline. Ammonia toxicity increases with increasing temperature and pH, and the CCME (2017) provides a table of guideline values for different pH values and temperatures. For the screen, the guideline value for a temperature of 20°C and a pH of

8.0 was selected, based on the monthly average temperature in Baker Creek in a warmer month (18.5°C for August 2015) and the average field pH over 2010 to 2015 (7.86). Temperature data are not available for Yellowknife Bay, and thus the guideline for Baker Creek was used. Although the average pH (7.65) is slightly lower in Yellowknife Bay than in Baker Creek, and the temperature would be expected to be as well, the use of the higher pH and temperature is conservative.

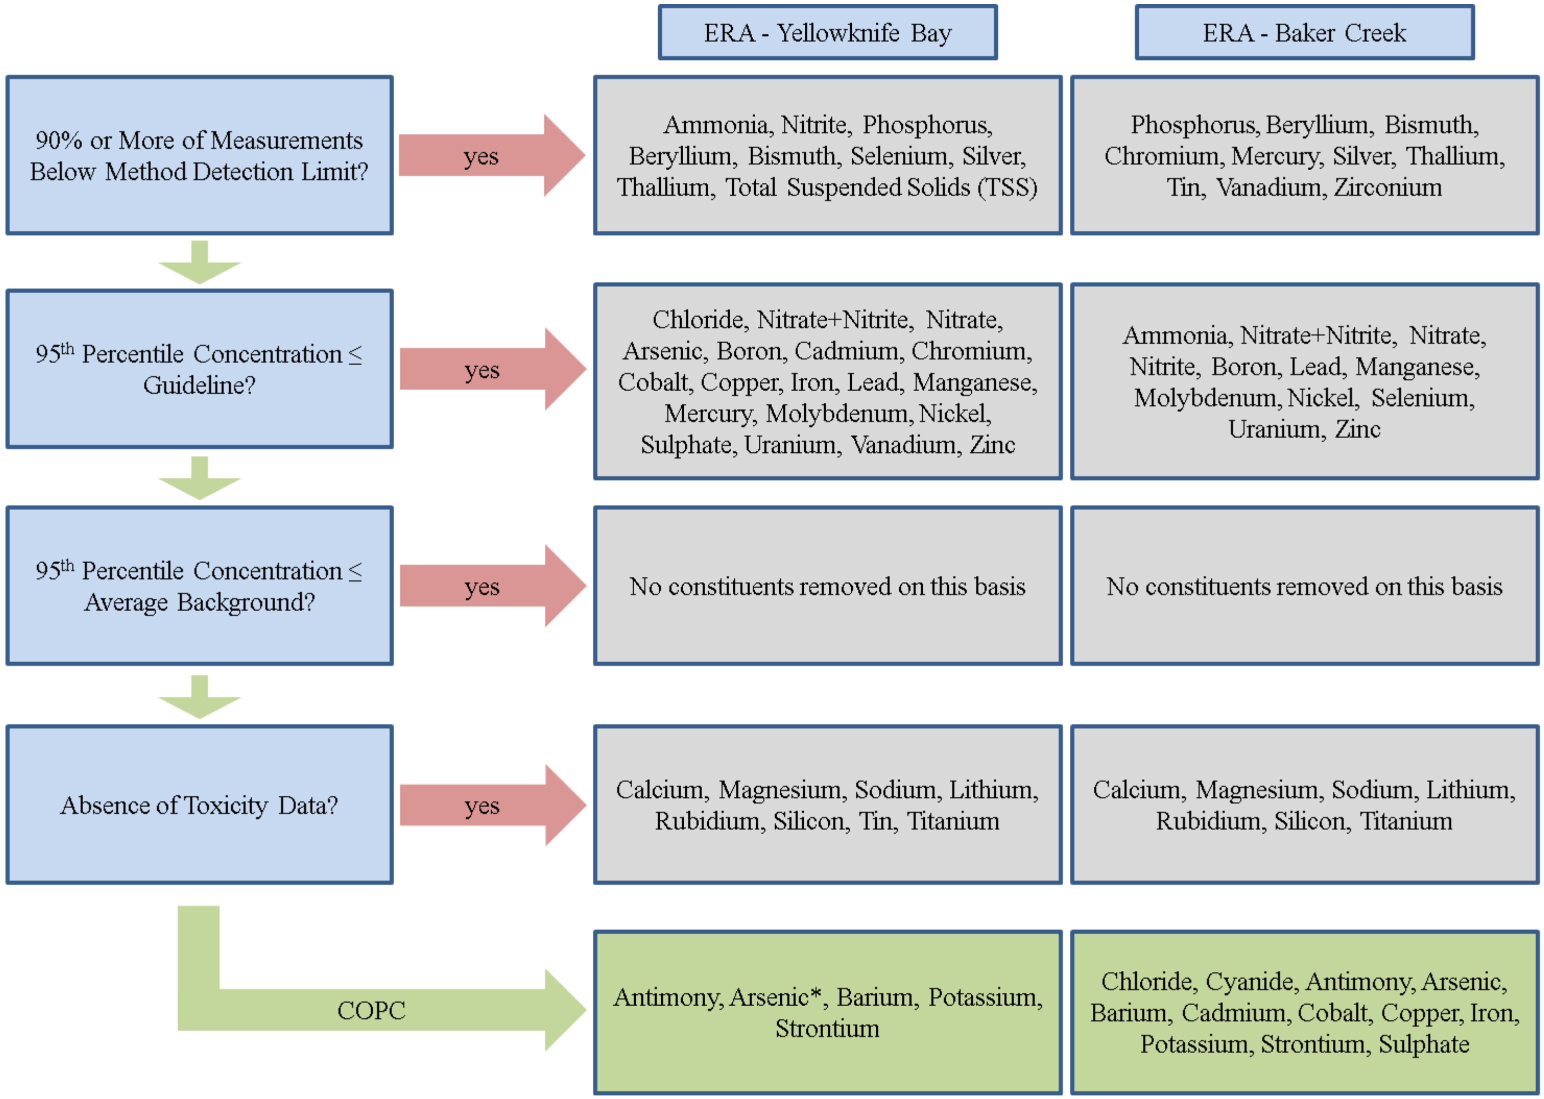
A summary of the screening process for COPC in surface water is provided in Figure D.4 for the HHRA and Figure D.5 for the ERA. Summary statistics of the considered data as well as the screening results are presented below in Table D.2 (for the HHRA screen in Yellowknife Bay), Table D.3 (for the ERA screen in Yellowknife Bay), and Table D.4 (for the ERA screen in Baker Creek).

Figure D.4 Flowchart of surface water constituents of potential concern screening results for the human health risk assessment



* Although arsenic concentrations were below the Health Canada Drinking Water Guideline in Yellowknife Bay, it was retained in the final list of COPC due to community concerns related to fish consumption and sediment contact.

Figure D.5 Flowchart of surface water constituents of potential concern screening results for the ecological risk assessment



* Although arsenic was below the aquatic life guideline in Yellowknife Bay, it was retained in the final list of COPC due to community concerns.

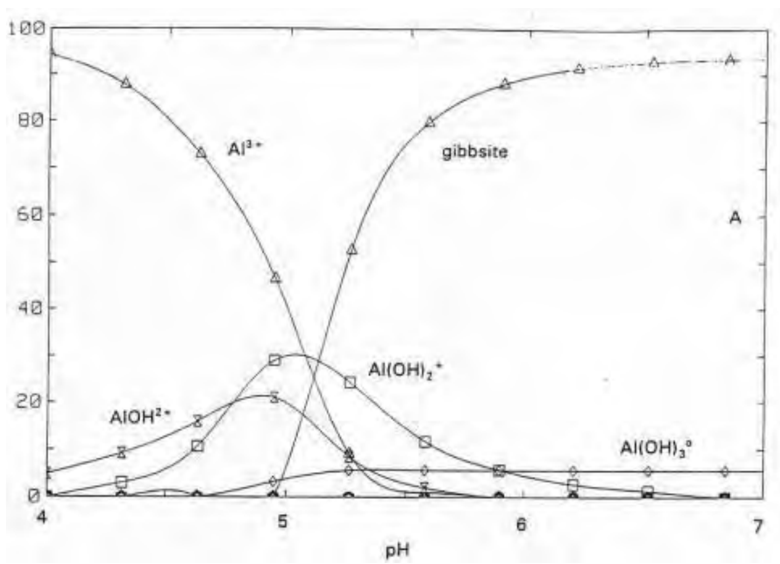
Following the screening procedure outlined in Figure D.1, the surface water COPC screen first identified constituents where the more than 90% of the data were below the MDL. As shown in Figure D.4 and Figure D.5, ammonia, nitrite, phosphorus, beryllium, bismuth, selenium, silver, thallium, and total suspended solids (TSS) were not considered further in Yellowknife Bay on the basis of 90% or more of measurements being below the MDL, while in Baker Creek (Figure D.5), phosphorus, beryllium, bismuth, chromium, mercury, silver, thallium, tin, vanadium, and zirconium were not considered further. The reported MDLs were examined closely to determine whether any of the COPC had detection limits above the water quality criteria. This investigation found that all the maximum reported MDLs were below the CCME aquatic guidelines (the most stringent water quality guidelines) and thus it is reasonable to exclude these constituents from further investigation.

As indicated in Figure D.4 for the HHRA and Figure D.5 for the ERA, the following constituents were dropped from further consideration on the basis of the 95th percentile of the measured concentrations being below the appropriate guideline:

- Yellowknife Bay (HHRA): chloride, sodium, nitrate+nitrite, nitrate, aluminum, antimony, arsenic, barium, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, strontium, tin, uranium, vanadium, and zinc.
- Yellowknife Bay (ERA): chloride, nitrate+nitrite, nitrate, arsenic, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, sulphate, uranium, vanadium, and zinc.
- Baker Creek (ERA): ammonia, nitrate+nitrite, nitrate, nitrite, boron, lead, manganese, molybdenum, nickel, selenium, strontium, uranium, and zinc.

Although the 95th percentile concentrations of the data for aluminum were above the aquatic life guideline in Baker Creek and Yellowknife Bay, additional considerations were included in the final determination for whether aluminum was a COPC. Aluminum is complexed by both inorganic and organic ligands in water (see Figure D.6). Below a pH of 6, organic complexes and the hydrated free ion tend to be the principal forms. At higher pH values, the dissolved species are only a small fraction of the total aluminum present since most of the aluminum is in a particulate form, which is inaccessible and therefore much less toxic than dissolved aluminum. At pH values between 5.5 and 9, there is very little aluminum that is in true solution and available for uptake by biological species (Gardner et al. 2002). Since the average pH is 7.65 in Yellowknife Bay and 7.86 in Baker Creek, aluminum is not considered to be in an available (toxic) form. In addition, measured data in Baker Creek support the conclusion that aluminium in Baker Creek is not in a dissolved (bioavailable) form. For example the mean total aluminum concentration in Upper Baker Creek is 0.086 mg/L and the corresponding mean dissolved aluminum concentration is 0.005 mg/L, indicating that approximately 5% of aluminum is in the dissolved form. Similarly in Lower Baker Creek, the mean total aluminum concentration is approximately 0.11 mg/L and the mean dissolved aluminum concentration is 0.0078 mg/L representing approximately 7% in a dissolved form. Thus, aluminum is not in a bioavailable form. It should be noted that in Yellowknife River (background location) the mean total and dissolved aluminum concentrations are the same as those measured in Lower Baker Creek. The treated effluent has a mean total aluminum concentration of 0.015 mg/L and thus there is also not a substantial load of aluminum associated with the Giant Mine. For all of these reasons, aluminum was not considered to be a COPC.

Figure D.6 Aluminum speciation in water from pH 4 to 7



Note: from Gensemer and Playle (1999).

The next step involved comparing the 95th percentiles of the measured data to background concentrations to determine which constituents are present at natural levels. Average background concentrations were developed from data obtained from three locations that have historically been considered background locations (see ATTACHMENT D.1): Yellowknife River, South Yellowknife Bay (near Horseshoe

Island), and Prosperous Lake. No additional constituents were removed the list of potential COPC on this basis.

The final step involved an evaluation of whether or not toxicity data were available for a constituent. The following constituents were removed on the basis of having no aquatic or human health toxicity data:

- Yellowknife Bay (HHRA): calcium, magnesium, potassium, rubidium, silicon, sulphate, and titanium.
- Yellowknife Bay (ERA): calcium, magnesium, sodium, lithium, rubidium, silicon, tin, and titanium.
- Baker Creek (ERA): calcium, magnesium, sodium, lithium, rubidium, silicon, and titanium.

The screening procedure is summarized in Table D.2, Table D.3, and Table D.4, as well as Figure D.4 and Figure D.5. No constituents were identified as COPC for the HHRA in Yellowknife Bay as all measured concentrations were below drinking water guidelines. For the ERA, antimony and barium were selected as COPC for both Yellowknife Bay and Baker Creek, while chloride, cyanide, arsenic, cadmium, cobalt, copper iron, and sulphate were also identified as COPC for Baker Creek. Even though arsenic concentrations in Yellowknife Bay were below both the drinking water guideline and the aquatic life guideline, it was retained as a COPC in Yellowknife Bay due to community concerns.

D.4 Constituents of Potential Concern in Sediment

A secondary screen was carried out for sediments to determine whether additional COPC would be identified. The screen was undertaken on sediments from Baker Creek and Yellowknife Bay. Data for total metals collected from May 2011 onwards were considered in the process to represent current conditions. For Baker Creek, data from all reaches downstream of Baker Pond were included, as well as data collected from Back Bay at the outlet of Baker Creek. For Yellowknife Bay, data from all areas were considered, including Back Bay near Latham Island, North Yellowknife Bay near Ndilo, and South Yellowknife Bay by Dettah. Due to the large number of measurements available for each location, the 95% UCLM concentrations of the measured data were used in the screening process. This is considered to be a reasonably conservative approach and representative of average concentrations.

In this secondary screening process, the 95% UCLM concentrations were compared to sediment quality guidelines for the protection of freshwater aquatic life for long-term exposure from the CCME (2017). This is essentially Step 2 of the screening process. Only those constituents with a guideline were considered in this step. If the 95% UCLM of the constituent was above the sediment quality guideline then it was considered to be a COPC and compared to the list from the surface water screen to determine whether it was already on the list or whether it should be added to the list. Summary statistics of the considered data as well as the screening results are presented in Table D.5 and Table D.6, for the ERA screen in Baker Creek and Yellowknife Bay, respectively. The results of this secondary screen indicated chromium, lead, mercury, and zinc were added to the COPC list for the Baker Creek ERA and chromium was added for the Yellowknife Bay ERA.

Table D.5 Selection of constituents of potential concern in sediment in Baker Creek for the ecological risk assessment

Constituent	Unit	Guideline	N	N<MDL	Minimum	Maximum	Average	St. Dev.	95% UCLM	95% UCLM ≤ Guideline?	Aquatic COPC?	Rationale

Note: Sediment quality guidelines for the protection of freshwater aquatic life for long-term exposure from the Canadian Council of Ministers of the Environment (CCME 2017).

D.5 Summary

The final list of COPC in soil, surface water, and sediment for the Giant Mine HHRA and ERA from this screening process is summarized in Table D.7.

Table D.7 Summary of constituents of potential concern for the human health and ecological risk assessment

Soil		Surface Water/Sediment		
ERA	HHRA	Yellowknife Bay – HHRA	Yellowknife Bay – ERA	Baker Creek - ERA
Antimony Arsenic Copper Lead Manganese Vanadium Zinc	Antimony Arsenic Cadmium Lead Manganese Vanadium	Arsenic	Antimony Arsenic Barium Chromium (*sed) Copper (*sed)	Chloride Cyanide Sulphate Antimony Arsenic Barium Cadmium Chromium (*sed) Cobalt Copper Iron Lead (*sed) Mercury (*sed) Zinc (*sed)

Note: Arsenic in Yellowknife Bay was measured below the drinking water guidelines as well as the guidelines for protection of aquatic life but was retained due to community concerns; *sed – identified based on the sediment screen only.

ATTACHMENT D.1

DEVELOPMENT OF BACKGROUND CONCENTRATIONS

APPENDIX D – ATTACHMENT 1: DEVELOPMENT OF BACKGROUND CONCENTRATIONS

This attachment provides an overview of the development of background concentrations in surface water and soil for use in screening for constituents of potential concern (COPC). Guidance from the Federal Contaminated Sites Action Plan (FCSAP 2015) indicates that background is representative of the true range of concentrations associated with the geographic area of the Giant Mine. Thus, the background samples selected for use in the COPC screen for the human health and ecological risk assessment (HHERA) were for areas in the local area around the Giant Mine but outside of the area of influence.

The FCSAP background document (2015) refers to guidance from the United States Environmental Protection Agency (U.S. EPA 2002) for developing an appropriate background concentration. This guidance uses an average concentration for background when comparing to exposure areas to determine the difference between background and exposure areas. This is the approach that was used for screening to identify the COPC.

SURFACE WATER

Average background concentrations used in the surface water COPC screen were calculated from data obtained from three background locations: Prosperous Lake, South Yellowknife Bay near Horseshoe Island, and Yellowknife River (Figure 1). For most constituents, 20 samples were available from Prosperous Lake (four sampling locations, South Yellowknife Bay (two sampling locations), and Yellowknife River (three sampling locations). The data used to calculate the average background surface water concentrations were obtained from five studies completed by Golder and Stantec from 2012 to 2014. All values below the method detection limit (MDL) were converted to ½ the MDL before calculating summary statistics (e.g., average, 95th percentile, and standard deviation). This approach was only used for the screening step. In the risk assessment, the detection limits were handled within the ProUCL program and no adjustments were made.

Table 1 provides a summary of the background statistics for all constituents used in the COPC screen.

SOIL

Average background concentrations used in the soil COPC screen were calculated from data reported in three studies (Stantec 2014; Stevens et al. 2015; Golder 2016), as well as till data collected in 1999, 2000, and 2001 by Daniel Kerr and compiled in the Geological Survey of Canada (GSC) database (Kerr 1999, 2000, 2001). The majority of the considered background data was obtained from the GSC database (Figure 2). The yellow outline on the figure represents the mineralized Greenstone Belt. The consideration of all background data, regardless of sampling location or depth, was appropriate as it is more representative of the regional background conditions. As there is a large set of data (n > 100 samples for most constituents), summary statistics could be calculated with confidence. All values below the MDL were converted to ½ the MDL before calculating summary statistics (e.g., average, 95th percentile, and standard deviation). This approach was only used for the screening step. In the risk assessment, the detection limits were handled within the ProUCL program and no adjustments were made.

Table 2 provides a summary of the background statistics for all constituents in soil used in the COPC screen.

ATTACHMENT D.2

METHOD DETECTION LIMIT TREATMENT SENSITIVITY ANALYSIS

APPENDIX D – ATTACHMENT 2: METHOD DETECTION LIMIT TREATMENT SENSITIVITY ANALYSIS

This attachment provides a discussion on the method detection limits in soils and surface water as well as a sensitivity analysis on using different treatment options for the method detection limit (MDL).

SOIL

Due to the size of the data set for soils, the investigation on MDLs focused on those constituents that were screened out on the basis of being heavily censored (i.e., 90% or more of the measurements being below the MDL). As a first step into the soil investigation, those constituents that were screened out on the basis of being heavily censored were reviewed, comparing the minimum and maximum reported MDL values to the agricultural soil quality guidelines from the Canadian Council of Ministers of the Environment (CCME 2017). The summary is as follows:

- Beryllium – 219 out of 224 measurements <MDL; maximum value of < 4.0 mg/kg is equal to the guideline (4 mg/kg). Therefore beryllium is not dropped from screening.

- Selenium – 219 out of 224 measurements <MDL; maximum reported MDL value of < 10 mg/kg is above the guideline (1 mg/kg). Looking at the entire dataset it was observed that detected levels of selenium were only associated with garden soils in Yellowknife. These are believed to be samples of imported soil and therefore not related to activities at the Giant Mine. Since selenium was not detected in any other soils in the study area it was dropped from further consideration. In addition, all of the MDLs are well below both the CCME (2017) human health component value (80 mg/kg) and the MOE (2011) Table 2 human health value (78 mg/kg), supporting the decision to drop selenium as a COPC in soil.

- Silicon – 43 out of 43 measurements <MDL; no guideline or background concentrations are available, however silicon was not measured in a single sample and was not expected to be associated with activities at the Giant Mine.

- Thallium – 203 out of 224 measurements <MDL; maximum value of 5.6 is above the guideline (1 mg/kg). However, only 16 of 224 measured concentrations or

reported MDL values are above the guideline, this represents less than 10% of the samples. In addition, thallium was not expected to be associated with activities at the Giant Mine and therefore is not considered further.

- Tin – 219 out of 224 measurements <MDL; maximum value of 4.0 mg/kg is below the guideline (5 mg/kg). Therefore tin was not considered further.

A sensitivity investigation was undertaken to examine the influence of detection limit treatment in generating summary statistics for the COPC screen. The investigation looked at the how the COPC screen outcomes would change if the <MDL values in both the background and exposure datasets were set to some of the common substitutions that are present in the literature (i.e., 0, 1/√(2) MDL, or MDL) instead of setting <MDL values equal to ½ the MDL (Antweiler 2015; Ogden 2010). This sensitivity investigation found that the treatment of the <MDL values has little influence on the final COPC list. The key differences as compared to the adopted approach (i.e, <MDL set to ½ MDL) are:

- Setting <MDL values to 0 – the t-test comparing background data to the Giant Mine concentrations found no statistically significant differences between the two datasets for uranium and would result in uranium being screened out during the initial phase of the screen. As uranium was screened out in the secondary screen by a comparison to the ecological and human health component values, this does not change the final COPC list.

- Setting <MDL values to 1/√(2) MDL or the MDL – the t-test comparing background data to the Giant Mine concentrations found no statistically significant differences between the two datasets for zinc and would result in zinc being screened out during the initial phase of the screen. Zinc is included in the final list of COPC for ecological receptors, demonstrating the conservative nature of using the ½ MDL approach.

These findings show that the COPC screen process is fairly robust with respect to MDL treatment and that setting <MDL values to ½ the MDL is a conservative approach as compared to the other methodologies considered.

SURFACE WATER

Due to the size of the data set for surface water, the investigation focused on those constituents that were screened out on the basis of being heavily censored (i.e., 90% or more of the measurements being below the MDL). As a first step into the investigation, those constituents that were screened out on the basis of being heavily censored were reviewed, comparing the minimum and maximum values to the human health (drinking water) and ecological protection (aquatic life) guidelines. It should be noted that the guidelines for the protection of aquatic life are more restrictive than the drinking water guidelines. For screening and statistical purposes, concentrations that were below the MDL were set equal to ½ MDL, however, in this investigation the MDL was used.

In Yellowknife Bay, the following constituents were classified as heavily censored:

- Total suspended solids (TSS), ammonia (as nitrogen), nitrite (as nitrogen), phosphorus, beryllium, bismuth, selenium, silver, and thallium.

There are no human health or ecological guidelines available for TSS, phosphorus, or bismuth and, as such, they were not investigated further.

- Ammonia – 190 of 195 measurements < MDL; maximum value of < 0.05 mg/L. Maximum measurable value of 0.01 mg/L. All are well below aquatic life guideline of 0.41 mg/L.

- Nitrite – all 161 measurements < MDL; maximum value of < 0.05 mg/L is below aquatic life guideline of 0.06 mg/L.

- Beryllium – all 199 measurements < MDL; maximum value of < 0.002 mg/L is below drinking water guideline of 0.005 mg/L.

- Selenium – all 199 measurements < MDL; maximum value of < 0.001 mg/L is equal to aquatic life guideline of 0.001 mg/L and below the drinking water guideline of 0.05 mg/L.

- Silver – all 199 measurements < MDL; maximum value of < 0.0001 mg/L is below aquatic life guideline of 0.00025 mg/L and drinking water guideline of 0.0188 mg/L.

- Thallium – all 199 measurements < MDL; maximum value of < 0.0001 mg/L is below aquatic life guideline of 0.0008 mg/L but above drinking water guideline 0.00004 mg/L. It should be noted that the drinking water guideline is based on the Regional Screening Level (RSL) for tap water from the United States Environmental Protection Agency (2016) divided by 5. The actual RSL is 0.0002 mg/L for various salts of thallium including chloride, acetate, selenite and nitrite. Further investigation notes that:
    - 145 samples have MDLs that are < 0.0001 mg/L and 54 samples have MDLs that are < 0.00005 mg/L
    - Maximum measured thallium concentration is 0.000025 mg/L in Baker Creek is below drinking water guideline.

Based on the above comparison of maximum MDLs/measured values, and the fact that the majority of the constituents were 100% undetectable, it is reasonable to exclude the above-listed constituents from the list of COPC for Yellowknife Bay.

In Baker Creek, the following constituents were classified as heavily censored:

- Phosphorus, beryllium, bismuth, chromium, mercury, silver, thallium, tin, vanadium, and zirconium.

There are no ecological guidelines available for phosphorus, beryllium, bismuth, tin, or zirconium and, as such, they were not investigated further. No comparison was made to drinking water guidelines since Baker Creek is not being evaluated for human exposure; however it should be noted that guidelines for the protection of aquatic life are more stringent than drinking water guidelines.

- Chromium – 271 of 288 measurements < MDL; max MDL is < 1 mg/L, which was raised from 0.001 mg/L due to matrix interference. Maximum measured concentration is 0.00071 mg/L, which is below aquatic life guideline of 0.001 mg/L.

- Mercury – 266 of 271 measurements < MDL; max MDL is < 0.0000026 mg/L, which was raised due to detection of mercury at similar level in method blank. Even still, an order of magnitude below aquatic life guideline (0.000026 mg/L). Max measured is 0.000051 mg/L, which is just above the guideline; however, this was in 2011, and the four other detectable concentrations since that time are below the guideline.

- Silver – 269 of 288 measurements < MDL; max MDL of < 0.1 mg/L is above guideline (0.00025 mg/L), but it was raised due to matrix interference. All MDLs that are above guideline (< 0.03 mg/L and <0.01 mg/L) were raised due to matrix interference. Maximum measured silver concentration is 0.000059 mg/L, which is well below guideline.

- Thallium – 277 of 288 measurements < MDL; max MDL of <0.6 mg/L is above guideline (0.0008 mg/L), but raised due to matrix interference. Other MDLs that are above guideline (< 0.2 mg/L and < 0.02 mg/L) were raised due to matrix interference. The maximum measured thallium concentration is 0.000025 mg/L, which is well below guideline.

- Vanadium – 281 of 288 measurements < MDL; max value of < 1 mg/L is above guideline (0.05 mg/L), but raised due to matrix interference. Same for other MDLs above guideline (< 0.09 mg/L and < 0.1 mg/L) and other MDLs are below the guideline. The maximum measured vanadium concentration is 0.0012 mg/L, which is below guideline.

Based on the above comparison of maximum MDLs/measured values, and the fact that the majority of the constituents were 100% undetectable, it is reasonable to exclude the above-listed constituents from the list of COPC for Yellowknife Bay.

ATTACHMENT D.3

MERCURY LEVELS IN YELLOWKNIFE

APPENDIX D – ATTACHMENT 3: MERCURY LEVELS IN YELLOWKNIFE

The Giant Mine Remediation Plan (GMRP) indicates that mercury amalgamation occurred from 1948 to 1959 even though the roaster came on line in 1949. Thus mercury may have been associated with the releases from the Giant Mine over 50 years ago. A recent paper by Thienpont et al. (2016) indicates that mercury in sediments from 1 core in Pocket Lake (a small lake on the Giant Mine) showed increases in concentrations when the mine was in operation and suggests that mercury was emitted from the roaster. It should be noted that mercury is always a concern in the north due to long-range transport.

Concentrations of mercury in various media (i.e., soil, water, sediment, and fish) were therefore examined further to determine whether mercury should be identified as a constituent of potential concern (COPC) in the human health and ecological risk assessment (HHERA). A statistical analysis was also conducted to determine if there was a significant difference between mercury levels in background and non-background areas, in addition to a comparison to available guidelines.

OVERVIEW

Mercury data from non-background areas as well as background areas in soils, water, sediment, and fish muscle were summarized and statistical tests were then carried out to determine whether the non-background and background data sets were different.

The following procedure was used to do the statistical comparison to background:

1. Samples from recent years (e.g., 2011 to present) were considered in the comparison as they were considered to be representative of current conditions.

2. Values below the method detection limit (MDL) were converted to ½ the MDL before calculating summary statistics (e.g., average, 95th percentile, and standard deviation) for this screening approach. Antweiler (2015) and Ogden (2010) indicate that for low degrees of censoring (<25%) and the number of observations between 20 and 100 that the substitution of ½ the MDL shows “fairly modest bias in the 95th percentile or the mean, and the imprecisions of these estimates are only slightly worse than the optimum method of data treatment”.

3. An F-test was conducted on the datasets to determine if the variances were equal or unequal. If the F-statistic is greater than the F critical one-tail, then the variances are

considered unequal. If the F-statistic is less than the F critical one-tail, then the variances are considered equal.

4. Based on the conclusion of the F-test, a T-test was conducted assuming either equal or unequal variances. If the T-statistic is greater than the t critical two-tail, the null hypothesis is rejected and the datasets are considered significantly different. If the T-statistic is less than the t critical two-tail, the null hypothesis cannot be rejected and the datasets are not considered significantly different.

SOIL

The levels of mercury in soil were investigated in background locations, non-background locations (sites around Yellowknife and Ingraham Trail) and on the Giant Mine. Mercury concentrations in soil at the Giant Mine, which would have been affected by deposition from any air emissions, ranged from 0.05 to 0.16 mg/kg; however, only a small data set was available (Table 1). The concentrations from Giant Mine are within the range of background measurements as well as off-site measurements. The 95th percentile for Giant Mine (0.16 mg/kg) is below the (CCME 1999) soil quality guideline of 6.6 mg/kg for agricultural land use.

The statistical comparison shows that mercury concentrations in off-site locations are similar to background (Table 2).

Table 1. Summary statistics for concentrations of mercury in soil

Location	N	N<MDL	Soil Concentration (mg/kg)				
			Min	Max	Mean	SD	95th Percentile
Background	31	5	0.0025	0.17	0.024	0.035	0.085
Non-background (off site)	27	3	0.0025	0.30	0.035	0.059	0.11
Giant Mine	4	0	0.05	0.16	0.113	0.049	0.16

Table 2. Statistic comparison of mercury concentrations in soil from background locations and non-background locations

Comparison	F-Statistic > F Critical One-tail	T-Statistic > T Critical Two Sided	Conclusion
Background vs. Non-background	Yes, the variances are not equal	No, cannot reject the null	Mercury levels in background and non-background locations are not statistically different, they are similar.

WATER

Although mercury generally partitions with soils and sediments and is not commonly found in surface water, comparisons of concentrations in water from 2011 to present in background locations, Yellowknife Bay locations (including Back Bay), and Baker Creek were conducted. Greater than 85% of all samples were below the MDL. Concentrations ranged from 5.0×10^{-6} to 5.1×10^{-3} mg/L, 2.5×10^{-7} to 1.2×10^{-5} mg/L, and 6.4×10^{-7} to 5.1×10^{-5} mg/L in background, Yellowknife Bay, and Baker Creek, respectively (Table 3).

Surface water samples from Yellowknife Bay and Baker Creek contained mercury concentrations that are lower than those from background areas (Table 4). All mercury concentrations are below the Health Canada (2017) drinking water guideline of 0.001 mg/L in Yellowknife Bay and in Baker Creek. There are four background samples that exceed the drinking water guideline; however, the majority of samples are all below the MDL.

Table 3. Summary statistics for concentrations of mercury in surface water

Location	N	N<MDL	Water Concentration (mg/L)				
			Min	Max	Mean	SD	95th Percentile
Background	30	26	5.0×10^{-6}	5.1×10^{-3}	4.6×10^{-4}	1.1×10^{-3}	2.6×10^{-3}
Yellowknife Bay	434	382	2.5×10^{-7}	1.2×10^{-5}	5.3×10^{-6}	3.9×10^{-6}	1.0×10^{-5}
Baker Creek	151	139	6.4×10^{-7}	5.1×10^{-5}	4.7×10^{-6}	4.0×10^{-6}	5.0×10^{-6}

Table 4. Statistic comparison of mercury concentrations in surface water from background, Yellowknife Bay, and Baker Creek

Comparison	F-Statistic > F Critical One-tail	T-Statistic > T Critical Two Sided	Conclusion
Background vs. Yellowknife Bay	Yes, the variances are not equal	Yes, reject the null	Mercury levels in background and Yellowknife Bay are statistically different.
Background vs. Baker Creek	Yes, the variances are not equal	Yes, reject the null	Mercury levels in background and Baker Creek are statistically different.

SEDIMENT

Comparisons of sediments from 2011 to present in background locations, Yellowknife Bay locations (including Back Bay), and Baker Creek were conducted. Concentrations ranged from 0.006 to 0.03 mg/kg dw, 0.003 to 0.26 mg/kg dw, and 0.007 to 1.06 mg/kg dw in background, Yellowknife Bay, and Baker Creek, respectively (Table 5). The highest concentrations of mercury were from samples obtained in Baker Creek downstream of the Giant Mine.

Sediment samples from Baker Creek contained mercury concentrations that are higher than those from background areas (Table 6). However, greater than a third of the samples were below the MDL. The CCME (1997) recommends an Interim Sediment Quality Guideline (ISQG) of 0.170 mg/kg dw and Probable Effect Level (PEL) of 0.486 mg/kg dw for the protection of aquatic life. The 95th percentile for Baker Creek (0.59 mg/kg dw) exceeds both the ISQG and the PEL, while the 95th percentiles for background and Yellowknife Bay locations (0.03 mg/kg dw and 0.14 mg/kg dw, respectively) are below the CCME ISQG.

Table 5. Summary statistics for concentrations of mercury in sediments

Location	N	N<MDL	Sediment Concentration (mg/kg dw)				
			Min	Max	Mean	SD	95th Percentile
Background	13	5	0.006	0.03	0.02	0.008	0.03
Yellowknife Bay	159	21	0.003	0.26	0.06	0.05	0.14
Baker Creek	203	77	0.007	1.1	0.12	0.19	0.59

Table 6. Statistical comparison of mercury concentrations in sediments from background locations, Yellowknife Bay and Baker Creek

Comparison	F-Statistic > F Critical One-tail	T-Statistic > T Critical Two Sided	Conclusion
Background vs. Yellowknife Bay	Yes, the variances are not equal	Yes, reject the null	Mercury levels in background and Yellowknife Bay are statistically different.
Background vs. Baker Creek	Yes, the variances are not equal	Yes, reject the null	Mercury levels in background and Baker Creek are statistically different.

Given the elevated concentrations of mercury in sediments in Baker Creek and the exceedance of the CCME ISQG, mercury in sediments was evaluated as a part of the ecological risk assessment (ERA) for Baker Creek.

FISH MUSCLE

Consultations with the Yellowknives Dene First Nation (YKDFN) indicate that fish species such as lake whitefish and inconnu are consumed by the community and important to their livelihood. Thus, mercury concentrations in flesh from these species were evaluated. Of the 42 background samples and 42 samples from Yellowknife Bay, none were below the MDL. Concentrations of mercury ranged from 0.03 to 0.18 mg/kg ww in background locations and 0.03 to 0.21 mg/kg ww in Yellowknife Bay locations (Table 7). There were significant differences in concentrations in fish caught in background locations than in fish caught in Yellowknife Bay (Table 8).

The 95th percentile in background and Yellowknife Bay locations (0.15 and 0.13 mg/kg ww, respectively) are below the Health Canada (2012) consumption guideline related to human health risk for total mercury in fish of 0.5 mg/kg ww.

Table 7. Summary statistics for mercury concentrations in fish muscle (lake whitefish and inconnu)

Location	N	N<MDL	Fish Muscle Concentrations (mg/kg ww)				
			Min	Max	Mean	SD	95th Percentile
Background	42	0	0.03	0.18	0.09	0.03	0.15
Yellowknife Bay	42	0	0.03	0.21	0.07	0.04	0.13

Table 8. Statistical comparison of mercury concentrations in background and Yellowknife Bay locations in fish (lake whitefish and inconnu)

Comparison	F-Statistic > F Critical One-tail	T-Statistic > T Critical Two Sided	Conclusion
Background vs. Yellowknife Bay	No, the variances are equal	Yes, reject the null	Mercury levels in background and non-background locations are statistically different but only slightly.

If northern pike and burbot are added to the data set the mercury concentrations range from 0.03 to 0.39 mg/kg ww and 0.03 to 0.47 mg/kg ww in background and Yellowknife Bay locations, respectively (Table 9), with the highest concentrations of mercury found in northern pike. This can be attributed to the predatory nature of northern pike and the biomagnification of mercury up the food chain. Concentrations of mercury in fish caught in Yellowknife Bay are just slightly different than in fish caught in background locations (Table 10).

The 95th percentile in background and Yellowknife Bay locations (0.26 and 0.37 mg/kg ww, respectively) are still below the Health Canada (2012) consumption guideline related to human health risk for total mercury in fish of 0.5 µg/g ww.

Table 9. Summary statistics for concentrations of mercury in muscle of all species of fish

Location	N	N<MDL	Fish Muscle Concentrations (mg/kg ww)				
			Min	Max	Mean	SD	95th Percentile
Background	68	0	0.03	0.39	0.12	0.07	0.26
Yellowknife Bay	74	0	0.03	0.47	0.13	0.11	0.37

Table 10. Statistical comparison of mercury concentrations in background and Yellowknife Bay for all fish species

Comparison	F-Statistic > F Critical one-tail	T-Statistic > T Critical Two Sided	Conclusion
Background vs. Yellowknife Bay	Yes, the variances are not equal	No, cannot reject the null	Mercury levels in background and non-background locations are not statistically different, they are similar

Conclusion

Mercury concentrations in soil at the Giant Mine are below CCME guidelines, while mercury concentrations in water are also below the Health Canada drinking water guideline. In addition, concentrations in fish are below the Health Canada consumption guideline related to human health risk for total mercury in fish, and the concentrations in fish consumed by the YKDFN community are not different from concentrations in fish from background locations. Thus, mercury will not be considered further in the human health risk assessment.

However, given the elevated levels of mercury in sediments in Baker Creek it will be carried forward in the ERA for Baker Creek sediments.

APPENDIX E

HUMAN HEALTH RECEPTOR CHARACTERISTICS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX E: HUMAN HEALTH RECEPTOR CHARACTERISTICS

E.1 General

Receptor characteristics are used along with other exposure assumptions to estimate potential exposure in the risk assessment. The following sections provide the characteristics assumed for the human receptors considered in the human health risk assessment (HHRA). Food intakes and diet composition were based on the information obtained from the dietary surveys conducted in the Yellowknives Dene First Nation (YKDFN) and Metis communities (see Section E.5). Other characteristics were obtained from Health Canada Guidance for conducting Preliminary Quantitative Risk Assessments at Federal Sites (Health Canada 2012a) and other literature sources, as noted.

E.2 Identification of Human Receptors

Identification of human receptors for evaluation in the HHRA was based on the problem formulation (Stantec 2015) as well as on findings from consultation activities undertaken since the start of the project. This receptor identification took into account the diversity of inhabitants of the City of Yellowknife, Latham Island, the Ingraham Trail area, and the communities of Ndilo and Dettah as well as the wide range of land uses among these groups. Consideration was also given to future land use where it is possible that people may reside at the former Giant Townsite area. There are no specific plans in terms of the future land use for the former Townsite; however, the risk assessment considered the most restrictive land use. Figure E.1 presents the general geographic regions of the areas that were considered. As indicated in the Problem Formulation (Stantec 2015), major groups that were considered within the HHRA include:

- People (adults, teens, children, toddlers) living in the City of Yellowknife. This also includes members of the Metis community.
- People (elders, adults, teens, children, toddlers) living in the community of Ndilo.
- People (adults, teens, children, toddlers) living on Latham Island, other than in the Ndilo community.
- People (elders, adults, teens, children, toddlers) living in the community of Dettah.
- People (adults, teens, children, toddlers) residing on the Ingraham Trail. There were some samples collected along the Ingraham Trail, and these samples were used to evaluate the residential exposure.

In addition to these receptors, a hypothetical receptor was also included:

- People (adults, teens, children, toddlers) residing at the Giant Townsite.

Concern had been expressed about children wading in shallow sediments in the communities of Ndilo and Dettah and also at the Marina near Latham Island. In addition, exposure to the beach at Long Lake and to shallow sediments had also been identified as a concern during consultations. Therefore, additional exposures were considered for people wading in shoreline sediments and playing on the beach, and all life stages were considered to be exposed to sediments.

Additional exposures were considered for ingestion of medicinal tea and mushrooms, ingestion of drinking water from different parts of Yellowknife Bay, ingestion of organ meats from moose, fish, and ptarmigan/grouse, and recreational use of the Giant Mine in the future, including berry collection.

Workers on the Giant Mine as well as Highway workers working close to the site have been identified as a potential receptor group. However, workers are not being included in the HHRA, as they have their own, very rigorous health and safety protocols and regulations. At the Giant Mine in particular, there are many programs in place and the urinary arsenic program for on-site workers would also capture the exposure of workers who live in the community. In addition, during the screening process for selecting constituents of potential concern (COPC; see Appendix D), the 95th percentile of Giant Mine soil data were compared to the human health industrial/commercial criteria from the Canadian Council of Ministers of the Environment (CCME) that are considered to be protective of worker exposure; only antimony was in exceedance of the human health industrial/commercial criteria. This also provides additional evidence to exclude workers from the evaluation. Antimony is known to be co-located with arsenic and, thus, safety procedures targeted at protection from arsenic exposure would protect workers from antimony exposure as well.

The students of the K'àlemì Dene School in Ndilo were also identified for consideration since there are some elevated arsenic soil concentrations in the school yard and they consume lunches of fish caught in Yellowknife Bay. In Ndilo, all soil samples are considered in the residential scenario, including the high arsenic samples measured in the soils. Eating fish from North Yellowknife Bay where nets are set to catch fish for school lunches was also considered. Exposures for children living in Ndilo are for a longer time period (i.e., 24 hours a day, 365 days a year) than when they are at school (i.e., 6 hours a day for a maximum of 300 days a year) and, thus, capture potential exposures at the school. Therefore, students at the school were not specifically selected for the assessment.

For each selected receptor group, a range of life stages (toddler, child, teen, and adult) were considered. Exposures for infants were not evaluated because it was assumed that they would be mainly consuming breast milk. It is not expected that COPC such as arsenic would be found at high concentrations in breast milk. Samanta et al (2007) supports this statement since they determined that breast milk was found to have low concentrations of arsenic, even when women were being exposed to high levels of arsenic in their drinking water. Carignan et al. (2015) conducted a study that compared breastfed infants to formula-fed infants and determined that breastfed infants had lower arsenic exposure than formula-fed infants. These studies support the exclusion of infants in the risk assessment.

Figure E.1 Human receptor locations

E.3 Identification of Exposure Pathways

The exposure pathways identified in the 2006 risk assessment (SENES 2006) and retained in the 2015 Problem Formulation (Stantec 2015) were reviewed to determine if any changes were needed for the HHRA. The two changes are related to garden produce and inadvertent ingestion of water while swimming, playing, or boating, as discussed below.

Figure E.2 shows the potential exposure pathways that were selected for the current HHRA. The pathways considered for different types of country foods were based on results from the 2017 Dietary Survey and the samples provided from the voluntary sampling program. The potential exposure pathways are as follows:

- Surface Water: People drink water from various sources. The municipal supply in Yellowknife comes from the Yellowknife River and people in the City of Yellowknife get pipe-borne water. In Latham Island, Ndilo and Dettah, the municipal water is delivered by tanker truck. However, there are also some members of the community in Ndilo and Dettah, as well as houseboaters, that indicate that they drink water directly out of Yellowknife Bay.
- Air: Metals such as arsenic may be present in the air that can be breathed in by individuals.
- Soil: Individuals can come into contact with soil by gardening and other activities, such as camping or being out on the land, and children and toddlers can get exposed by playing with soil. Chemicals in the soil can get into the skin by these activities, and the soil on hands can end up in mouths and be eaten. Exposures can occur outside the home and if people are allowed to go to the Giant Mine in the future for some recreational activities where they can be exposed to soils on the Giant Mine.
- Dust: Dust in the house can have similar exposures to soil and can be present on hands and then ingested through hand-to-mouth contact. This is especially important in the winter when the soil outside is frozen.
- Sediment: Children have been reported to wade in shallow water along the shores of the Ndilo and Dettah communities as well as near the marina and other areas on Latham Island, and concern has been expressed about this activity. In addition, playing on the beach can result in sediments getting on hands and then being transferred to the mouth. Sediment can also stick on the skin. The assessment

considers all life stages for wading in shallow sediment and being exposed to beach sediments.

- Fish: The City of Yellowknife and surrounding communities are located on Yellowknife Bay and, from the dietary survey, it was reported that a large proportion of people eat fish from different areas in the bay. Fish flesh and liver samples were collected from different kinds of fish in different locations in Yellowknife Bay.
- Moose: Due to the fact that caribou cannot be hunted in the area any more, the dietary survey indicated that people are eating more moose. Moose flesh samples as well as organ (liver) samples were collected from the community.
- Grouse/ptarmigan: The dietary survey indicated that people eat both grouse and ptarmigan from the area. Flesh samples, as well as heart, liver, and gizzard samples, were also obtained from the community.
- Rabbit: The dietary survey indicated that people eat rabbit from the area. Information from other studies was considered along with samples from the community.
- Duck: People reported that they ate duck. Duck flesh samples were collected from the community.
- Medicinal Plants: In the dietary survey, people indicated that they drank Labrador tea, especially when they were on the land. In addition, they ate different medicinal plants, such as rat root and birch bark. Currently, there are samples of Labrador tea, and this is used as a surrogate for all medicinal plants.
- Berries: People collect berries from different locations across the study area. Many of the berries are collected at a distance from the Giant Mine; however, children in Ndilo have been reported to eat berries from local bushes. Samples have been collected from the community to represent exposure in all these areas.
- Mushrooms: The Metis community has indicated that their members eat mushrooms. Only a few mushroom samples have been provided by the community to examine this pathway.

In some communities, the drinking water supply may be obtained from groundwater wells. In the case of the City of Yellowknife and the surrounding communities, drinking water is obtained from the Yellowknife River or Yellowknife Bay. Given that these surface water sources are large and that there is no indication that the source of the municipal water system is likely to change, groundwater was not considered to represent a route of exposure.

People do have vegetable gardens in the area; however, it was determined that most of the soil in these gardens (which are generally raised) comes from outside of the area or from compost from the City. An examination of the chemical concentrations in both the garden soil and compost indicated that concentrations were no different from background soil concentrations and, thus, were not influenced by the Giant Mine. In addition, in 2001 a risk assessment was carried out by the Royal Military College (ESG 2001) related to exposure to arsenic from eating vegetables from backyard gardens in Yellowknife. This assessment involved the collection of soils and 61 different garden vegetables from 10 gardens across Yellowknife. The assessment considered the individual gardens as well as a garden that they considered to be representative of a typical resident in Yellowknife. The report concluded that even though residents in Yellowknife may eat garden vegetables with arsenic concentrations that are 10 times higher than in supermarket vegetables, when the amount of food consumed is considered there was no significant increase to the total daily intake of arsenic and therefore no indication that there was an increased health risk.

Between 2009 and 2012, the City of Yellowknife carried out a Centralized Composting Pilot Project (CCPP), the process and analytical requirements of which are documented in the following report:

- *Ripley 2012 Yellowknife centralized composting pilot project final report (contains data on two batches of finished compost from 2011 and 2012).*

Prior to selling the finished compost, trace elemental analysis must be conducted to ensure that the compost meets the CCME Category A compost requirements. For arsenic, this means that the concentrations must be below 13 mg/kg. As shown in

Table E.1, the average concentration of arsenic in compost of 22.1 mg/kg is above this criterion. The minimum value of 5.6 mg/kg was from the first batch of compost, while all subsequent batches have had higher concentrations as a result of an increasing proportion of yard waste in the compost (Ripley 2012). However, as discussed in Ripley (2012), these concentrations are consistent with the elevated background levels of arsenic in Yellowknife as compared to other regions of Canada. The average concentration is also below the average value for arsenic measured in soil samples from six gardens in the City of Yellowknife of 30.0 mg/kg (YCGC 2013). Therefore, garden produce was not considered in the assessment.

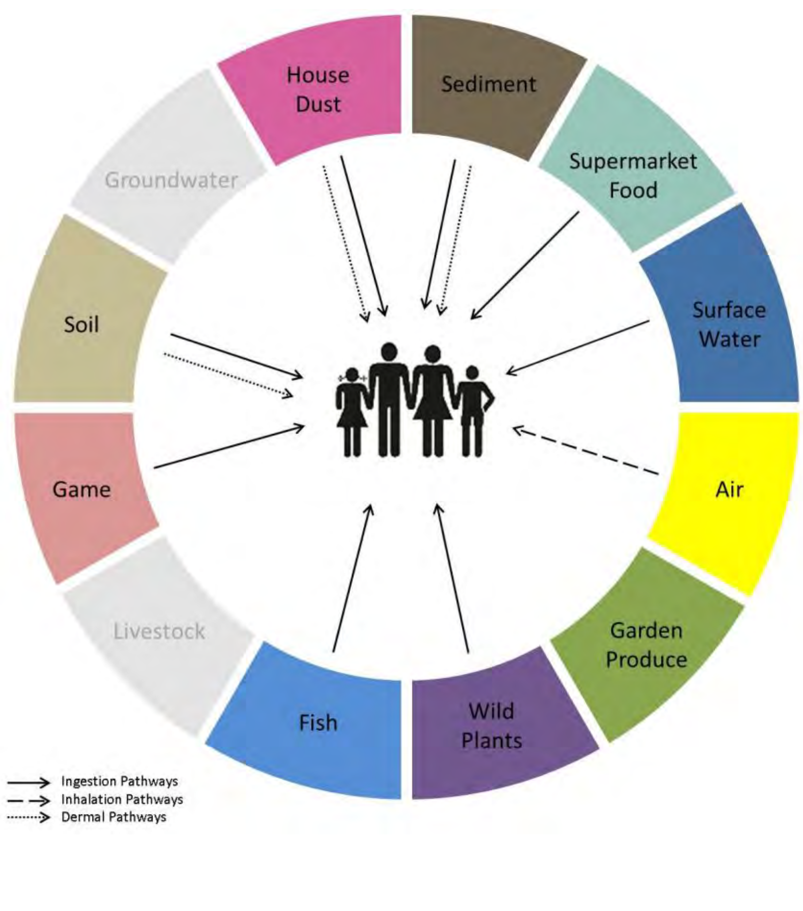
Table E.1 Summary of arsenic data availability and statistics – compost

Geographic Area	Years	N	N<MDL	Minimum	Maximum	Average	Standard Deviation
Yellowknife	2011, 2012, 2013, 2014	7	0	5.6	35.8	22.1	9.11

Note: Concentrations are in mg/kg; N – number of samples; N<MDL – number of samples below the Method Detection Limit (MDL).

Another pathway that was highlighted in the original Problem Formulation (Stantec 2015) was the ingestion of Yellowknife Bay water while swimming, playing on the shore, or boating. The risk assessment considers a resident drinking water from Yellowknife Bay and, thus, encompasses the exposure from these activities, as drinking water everyday represents a larger exposure than swimming, boating, or playing in Yellowknife Bay. City of Yellowknife residents were assumed to swim in Long Lake.

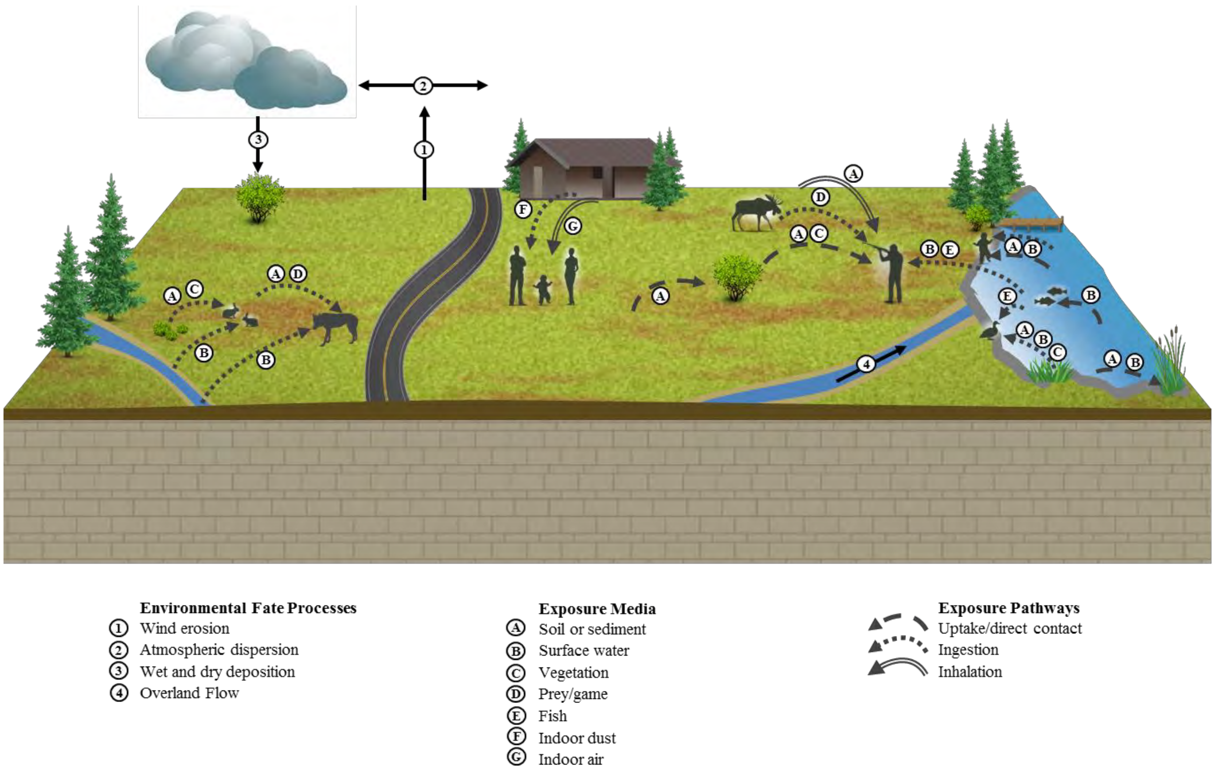
Figure E.2 Exposure pathways for HHRA



E.4 Conceptual Site Model

The Conceptual Site Model (CSM) for the Giant Mine HHRA is presented in Figure E.3. Note that this figure is a conceptual representation of the types of pathways and transport mechanisms considered in the HHRA and does not necessarily include every evaluated pathway/mechanism.

Figure E.3 Conceptual site model for HHRA



E.5 Dietary Survey

Within each community or population, there is diversity in the type and intensity of land use, country food gathering, and food consumption patterns. For the HHRA, data are available from studies conducted on Dene/Metis communities in 1996 and 1998 by the Centre for Indigenous Peoples' Nutrition and Environment (CINE; Receveur et al. 1996, 1998). These studies were comprehensive studies at the time. However, there have been dietary changes over the last 20 years mainly pertaining to the ban on caribou hunting and thus other wild game has been used as a substitute for the lack of caribou meat in the YKDFN diet. Discussions with the YKDFN indicated that an update to the dietary survey was necessary. Therefore, in 2017, three dietary survey workshops were held, and a dietary survey questionnaire was developed to gather additional information on YKDFN and North Slave Metis Alliance (NSMA) to inform the risk assessment and reduce uncertainty. This survey collected further specifics regarding the types and amounts of country foods consumed, as well as locations where hunting, trapping, fishing, and gathering take place.

The questions that were used in the workshops and questionnaire were primarily based on the voluntary samples that were collected (Appendix B), since these data formed the basis of the risk assessment. The questionnaire used for the workshops is provided in ATTACHMENT E.1.

E.5.1 Survey Methods

In conducting the workshops and questionnaires, the study team asked for groups of 20 people from the Ndilo, Dettah, and NSMA communities. The demographics that were targeted were the following:

- 16 to 19 years – 2 males and 2 females
- 20 to 39 years – 3 males and 3 females
- 40 to 59 years – 3 males and 3 females
- 60 plus – 2 males and 2 females

Indigenous and Northern Affairs Canada (INAC) worked with the community members to fulfil the requirements for the survey.

At the workshops, a presentation was given to each group to provide an overview of the results of the previous studies. Each workshop group was separated into smaller groups of around 3 to 5 people with a CanNorth representative asking questions and recording the results. In groups containing elders, a translator was present to facilitate communication.

The NSMA requested an electronic copy of the survey; this was developed in an online format and provided to the community.

E.5.2 Results of the Survey and Questionnaire

E.5.2.1 Participants

A total of 36 people from the YKDFN participated in the 3 in-person workshops. There were 28 males and 8 females. There were 9 people in the 20-to-39 year age group; 14 people in the 40-to-59 year age group; and 13 people in the 60-plus age group. No participants were in the 16-to-19 age group.

A total of 10 people completed questionnaires from the NSMA. There were 5 males and 5 females that completed questionnaires. Of the participants, 1 person was in the 12-to-19 age group; 2 people were in the 20-to-39 age group; 4 people were in the 40-to-59 age group; and 3 people were in the 60-plus age group.

Overall, there were 46 people who participated in the 2017 Dietary Survey.

E.5.2.2 Consumption of Traditional Food

Figure E.4 provides a summary of the percentage of traditional food that YKDFN participants said they consumed.

Over three quarters of the participants from both NSMA (Figure E.5) and YKDFN communities said that 30% or less of their diet is traditional foods.

Of the remaining YKDFN participants, a few people (5) reported eating between 40 % and 60% traditional foods; and another 5 people reported that they consume mostly (i.e., around 95%) traditional foods. Most of the high consumers of traditional food were in the 40 to 59 year age group. Of the elders surveyed, only 2 reported consuming more than 50% of traditional foods; the other 14 elders reported consuming 25% or less traditional foods. The person in the under-20 age group reported eating a diet consisting of approximately 25% traditional foods.

Figure E.4 Summary of reported traditional food content of the YKDFN diet

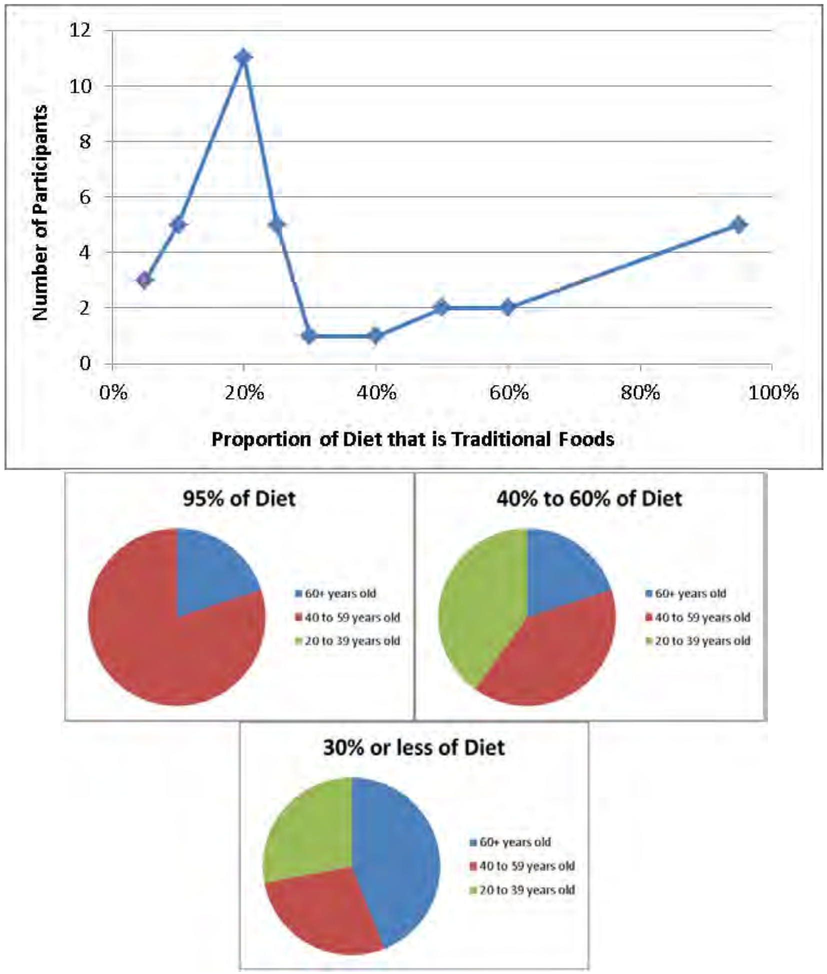


Figure E.5 Summary of reported traditional food content of the NSMA diet

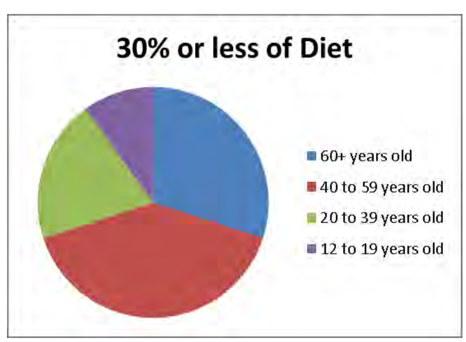


E.5.2.3 Dietary Breakdown

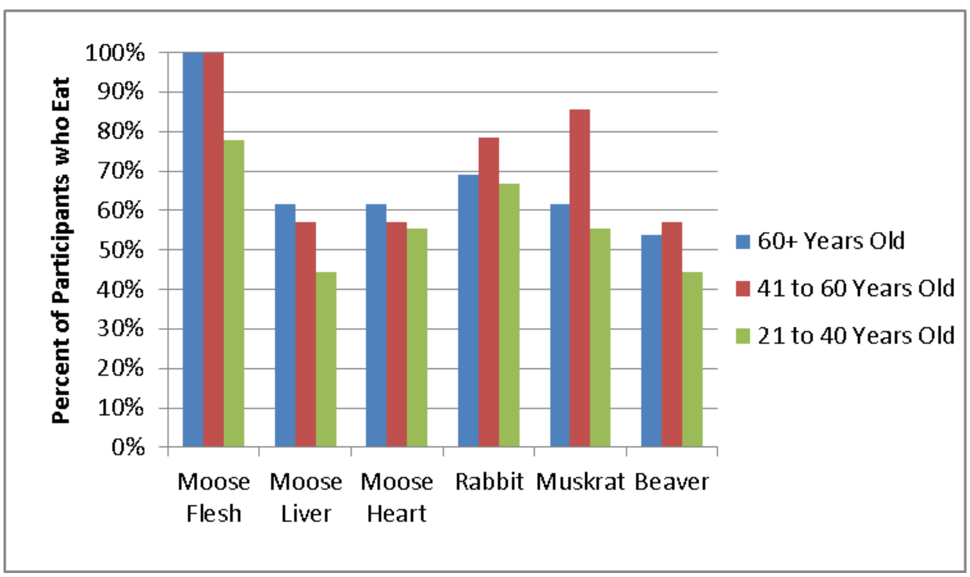
The following is a summary of each type of food discussed during the workshop and in the questionnaire, including what proportion of YKDFN and NSMA participants reported eating each item and how often these food items may be consumed.

Mammals

The mammals included in the 2017 Dietary Survey were moose, rabbit, muskrat, and beaver. Participants were asked about their consumption of caribou given that caribou hunting does not occur in the Yellowknife area and they were asked how they replaced caribou consumption in their diet. The majority of the participants indicated that they replaced it with store-bought food augmented with some additional traditional foods.

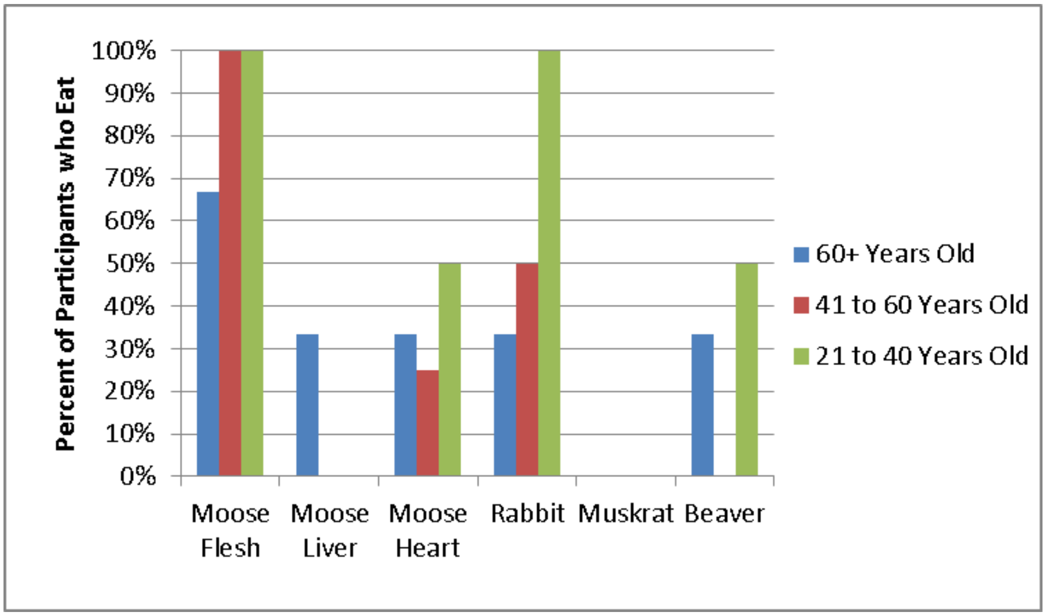
As can be seen from Figure E.6, most YKDFN participants (93%) reported eating moose flesh, with around half of participants eating moose liver (46%) and moose heart (52%). The previous dietary survey in the late 1990s indicated that about 53% of the YKDFN ate moose flesh, and about 30% ate heart and liver. This indicates that the consumption of caribou has possibly been replaced by the consumption of moose. Parents with children in their households said that children would eat moose flesh and perhaps moose heart but were less likely to eat moose liver. The participant in the under-20 age group indicated that they did not eat moose heart or liver.

Figure E.6 Percentage of YKDFN survey participants who reported consuming different mammals



Of the NSMA participants, 92% reported eating moose flesh, while less than a third of participants reported eating moose organs (Figure E.7).

Figure E.7 Percentage of NSMA survey participants who reported consuming different mammals



Seventy percent (70%) of YKDFN participants reported eating rabbits and fewer people reported eating muskrat (54%) or beaver (46%). None of the NMSA participants reported eating muskrat and about 40% of the participants reported eating beaver. Most of the participants indicated that beaver meat was very oily and, therefore, they did not like to eat as much. In the previous survey, about 25% of the participants said that they ate rabbit and about 30% said that they ate muskrat and 22% said that they ate beaver. Again, this suggests that people are substituting other wild game to replace at least some of the caribou that they used to consume. Additionally, participants reported that children would eat rabbit but would not generally eat muskrat or beaver. The participant in the under-20 age group indicated that they did not eat muskrat or beaver.

The previous survey found that, for those who ate moose, it was consumed around 17 times a year on average (or once every three weeks). This average moose flesh consumption rate is generally in line with the findings from the 2017 Dietary Survey where, with a few exceptions, people reported eating moose 17 times a year or less. Overall, the frequency ranged from 1 to 2 times per year up to around 60 times per year for the people with a diet that was mostly traditional food.

The previous survey found that moose liver was consumed 10 times per year, on average. This is high compared to the responses from the 2017 Dietary Survey, where all respondents who consumed moose liver said they consumed moose liver only a few times a year. Similarly, people reported eating moose heart a few times per year.

The previous survey found that, on average people consumed rabbit and muskrat around 17 times per year and beaver around 10 times per year. The 2017 Dietary Survey found that generally people consume these foods less often than previously reported with the exception of a few high traditional food eaters. Other than the few exceptions, people reported eating rabbit between 1 and 12 times per year; muskrat between 1 and 10 times per year; and beaver between 1 and 4 times per year. The higher traditional food participants reported eating rabbit up to 60 times per year, muskrat up to 20 times per year, and beaver up to 24 times per year.

In addition to the species shown above, several participants reported eating some caribou meat and reindeer meat, and one person reported that they eat bear when it is convenient.

Birds

The avian species that were included explicitly in the 2017 Dietary Survey were grouse, ptarmigan, duck, and Canada goose. Figure E.8 presents a summary of the YKDFN participants who reported consuming different types of birds. Around 66% of YKDFN participants reported eating grouse, ptarmigan (66%), and duck (83%) with slightly fewer reportedly eating Canada goose (69%). The previous survey indicated that about 50% of participants ate ptarmigan and duck, about 31% ate Canada goose, and only 20% reported consuming grouse. Thus, there is an increase in the amount of people consuming game birds compared to the previous study. Participants reported that children in their households would eat grouse, ptarmigan, duck, and Canada goose if adults in the household were consuming these foods. Participants from NSMA (Figure E.9) reported eating grouse (72%), ptarmigan (53%), and duck (39%) with only people 60 years and older reportedly eating Canada goose (22%). The participant in the under-20 age group indicated that they only ate grouse and ptarmigan.

Figure E.8 Percentage of YKDFN survey participants who reported consuming different birds

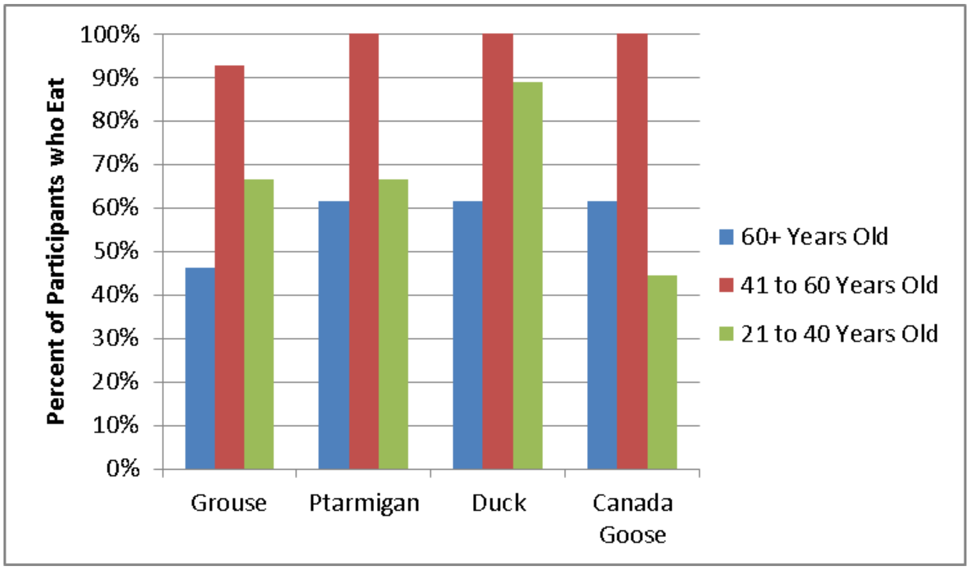


Figure E.9 Percentage of NSMA survey participants who reported consuming different birds

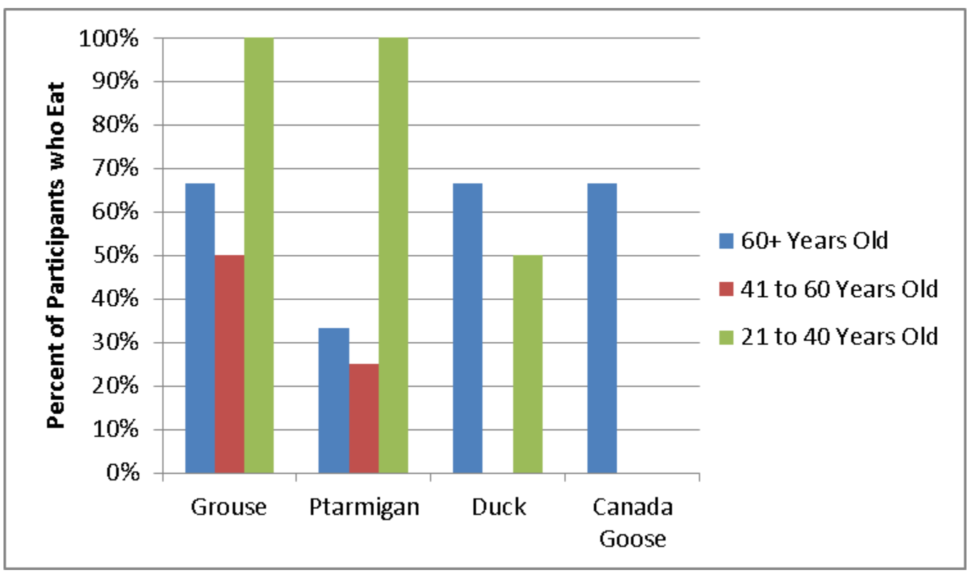

The 2017 Dietary Survey found that, with the exception of a few high traditional food consumers, people eat grouse between 1 and 8 times per year, ptarmigan between 1 and 16 times per year, duck between 1 and 20 times per year, and Canada goose between 1 and 12 times per year. The high traditional food consumers reported eating grouse up to 20 times per year, ptarmigan up to 50 times per year, duck up to 50 times per year. No people reported eating goose more than 8 to12 times per year. The average consumption frequency reported for all of these avian species was below the result from the previous study where, on average, people reported eating grouse around 10 times per year, ptarmigan around 10 times per year, duck around 17 times per year, and Canada goose around 10 times per year.

Fish

Fish that were explicitly included in the 2017 Dietary Survey included whitefish, lake trout, inconnu, and northern pike. Figure E.10 presents a summary of the proportion of YKDFN participants who reported eating these types of fish. The most people reported eating whitefish (80%), followed by trout (69%) with fewer people consuming northern pike (37%) or inconnu (19%). The previous survey indicated that 85% of people ate whitefish, 78% ate trout, and 20 % ate inconnu; thus, the current survey and the previous survey indicate that in general the types of fish consumed have not changed. The general consensus among people with children in their household is that the children typically eat whatever type of fish the parents are eating. Of the NSMA participants, all reported eating whitefish (100%) and trout (100%), with fewer people consuming northern pike (64%), and only people 60 years and older consuming inconnu (11%). The participant in the under-20 age group only indicated that they ate whitefish.

The fish consumption frequency from the 2017 Dietary Survey was fairly similar to the findings from the previous study where, on average, people at whitefish around 50 times per year, trout around 21 times per year, inconnu around 17 times per year, and northern pike around 10 times per year. Participants in the 2017 Dietary Survey reported consuming whitefish between 2 and 100 times per year, with most consuming between 30 and 50 times per year. People reported eating trout between 1 and 50 times per year, with most consuming between 20 and 25 times per year. People who consume inconnu reported that they eat it between 1 and 20 times per year and most people reported eating northern pike between 4 and 12 times per year, with a few higher eaters reporting eating pike up to 50 times per year.

In addition to the four species of fish discussed above, a number of participants said they consume pickerel, loache, mariah, or lingcod.

Figure E.10 Percentage of YKDFN survey participants who reported consuming different fish

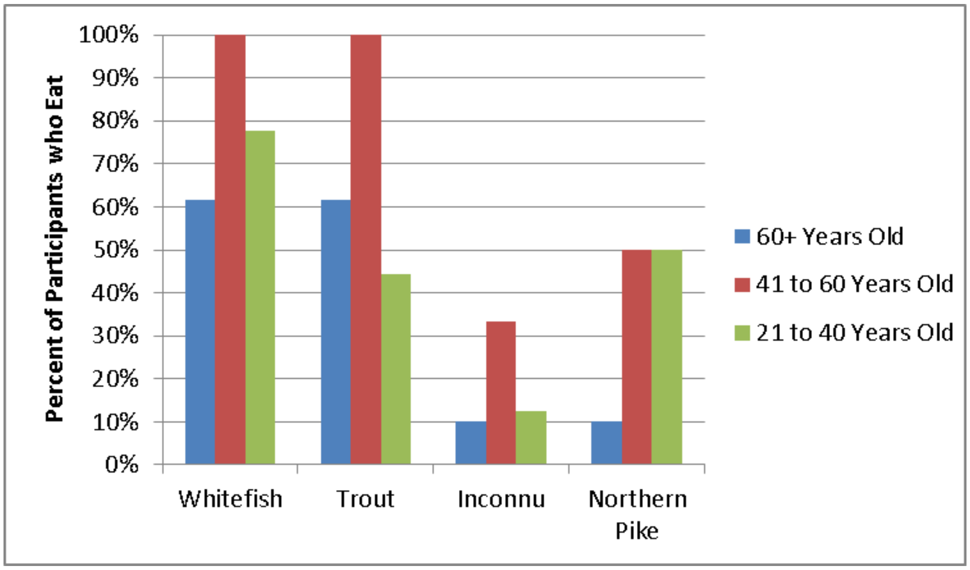

Figure E.11 Percentage of NSMA survey participants who reported consuming different fish

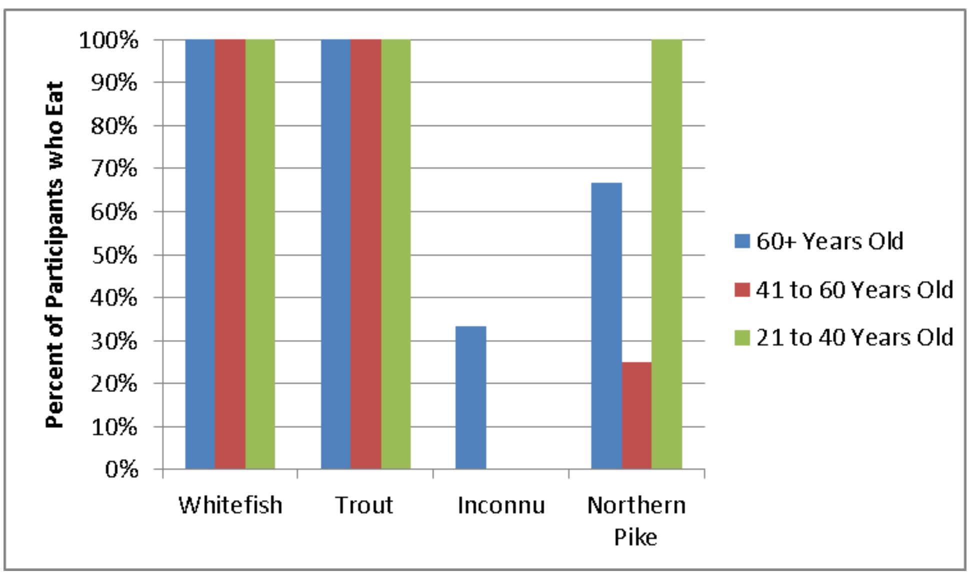

Plants

The types of plants explicitly included in the 2017 Dietary Survey included berries, rosehips, Labrador tea, mushrooms, and chives; an overview of the proportion of YKDFN participants who reported consuming each of these items is provided in Figure

E.12. Most people reported consuming berries (76%), and more than 70% respondents drink Labrador tea (71%), while fewer people reported consuming chives (29%), rosehips (22%), and none reported eating mushrooms. The previous survey indicated that about 58% of people consumed berries, 15% consumed Labrador tea, 7% consumed rose hips, and 4% consumed mushrooms and chives. The survey found that children generally ate locally sourced berries, and some would get Labrador tea at school, while few consume rosehips. Of the NMSA participants, most people reported consuming berries (81%), and about half of respondents consuming mushrooms (47%), while fewer people reported consuming chives and rosehips (17%), or Labrador tea (11%) (Figure E.13). The person in the under-20 age group only indicated that they only consume berries.

The previous study found that, on average, people reported consuming berries 1 to 2 days per week when in season; the average berry consumption frequency from the 2017 Dietary Survey was lower than this, with people reporting berry consumption generally between 5 and 30 times each year.

The previous study reported average consumption rates for rosehips, Labrador tea, mushrooms, and chives of 26 times per year, 76 times per year, 10 times per year, and 52 times per year, respectively. These numbers are all at the high end of the ranges reported by participants in the 2017 Dietary Survey, where rosehips were consumed a maximum of 12 times per year, Labrador tea was consumed a maximum of 52 times per year, mushrooms were consumed a maximum of 12 times per year, and chives were consumed a maximum of 52 times per year.

In addition to the five plants mentioned above, a number of people brought up rat root and spruce gum and reported consuming small amounts of it for medicinal purposes periodically.

Figure E.12 Percentage of YKDFN survey participants who reported consuming different plants

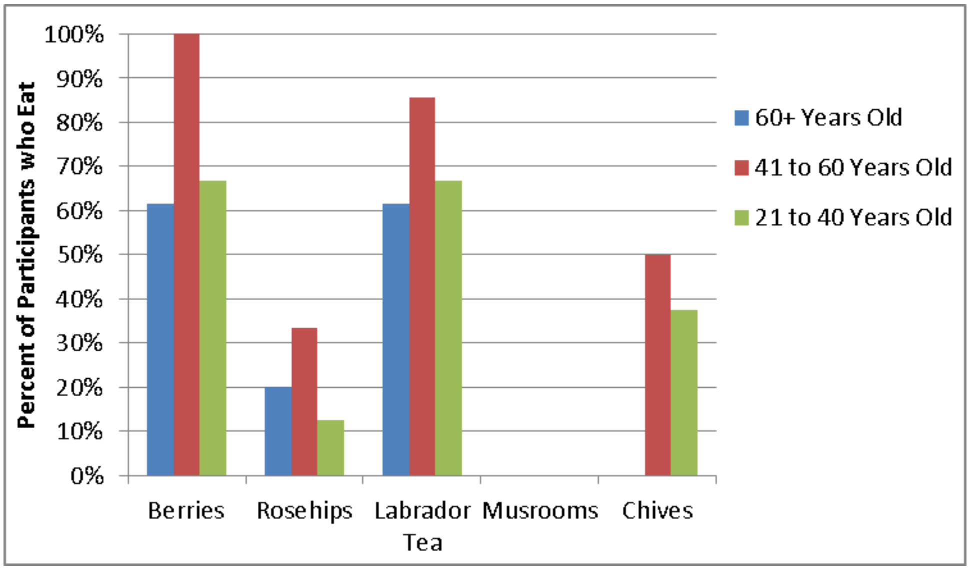

Figure E.13 Percentage of NSMA survey participants who reported consuming different plants

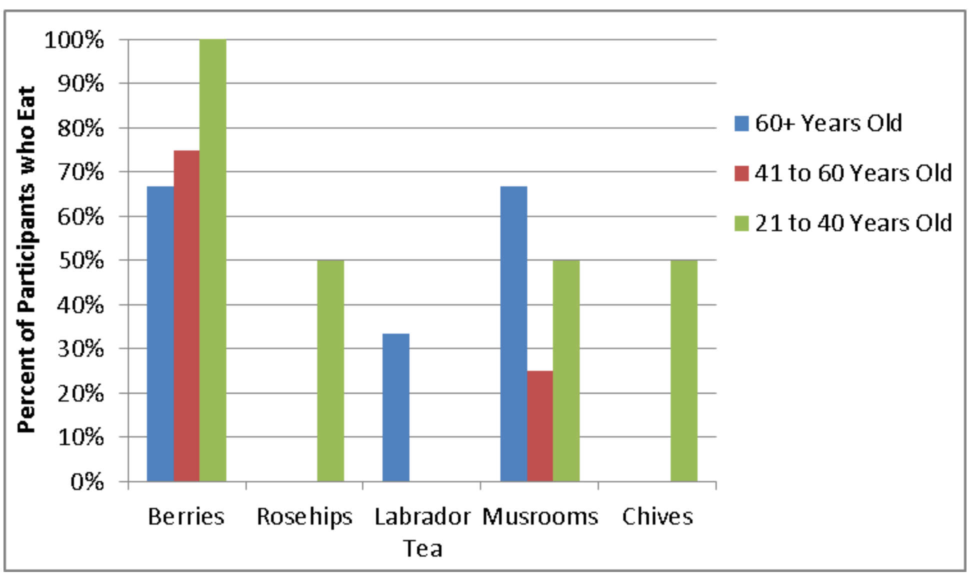


Traditional Food Portion Size

In addition to number of people who consume each food type and frequency of food consumption, another important piece of information is typical portion size for each of these traditional foods. Table E.2 presents the maximum and minimum amount of food people reported eating in the 2017 Dietary Survey. It should be noted that a portion size for meat and fish was defined as the palm of a hand, which represented 3 oz. (85 g). For rabbit, the minimum reported amount corresponds to a person eating about three whole rabbits a year, and for grouse/ptarmigan, the minimum reported amount also corresponds to eating about three grouse a year.

The 2017 Dietary Survey indicated that people ate about ½ c to 1½ c of berries, ¼ c to ½ c rose hips; ½ c to 1 c of mushrooms, and about 1 tbsp of chives.

The 2017 Dietary Survey has also captured some of the characteristics of a high traditional eater. These different consumption rates were used to determine the diets used in the HHRA.

Table E.2 Summary of findings of Dietary Survey

Food Item	2017 Dietary Survey	
	Minimum (g)	Maximum (g)
Caribou meat	85 (1 portion) [a]	255 (3 portions) [a]
Moose meat	85 (1 portion)	255 (3 portions)
Moose Liver	85 (1 portion)	85 (1 portion)
Moose Heart	45 (½portion)	85 (1 portion)
Rabbit	45 (½portion)	255 (3 portions)
Muskrat	45 (½portion)	170 (2 portions)
Beaver	85 (1 portion)	170 (2 portions)
Whitefish flesh	45 (½portion)	255 (3 portions)
Trout flesh	45 (½portion)	255 (3 portions)
Inconnu	85 (1 portion)	170 (2 portions)
Pike	85 (1 portion)	255 (3 portions)
Grouse	45 (½portion)	255 (3 portions)
Ptarmigan	45 (½portion)	170 (2 portions)
Duck	85 (1 portion)	255 (3 portions)
Canada Goose	85 (1 portion)	255 (3 portions)

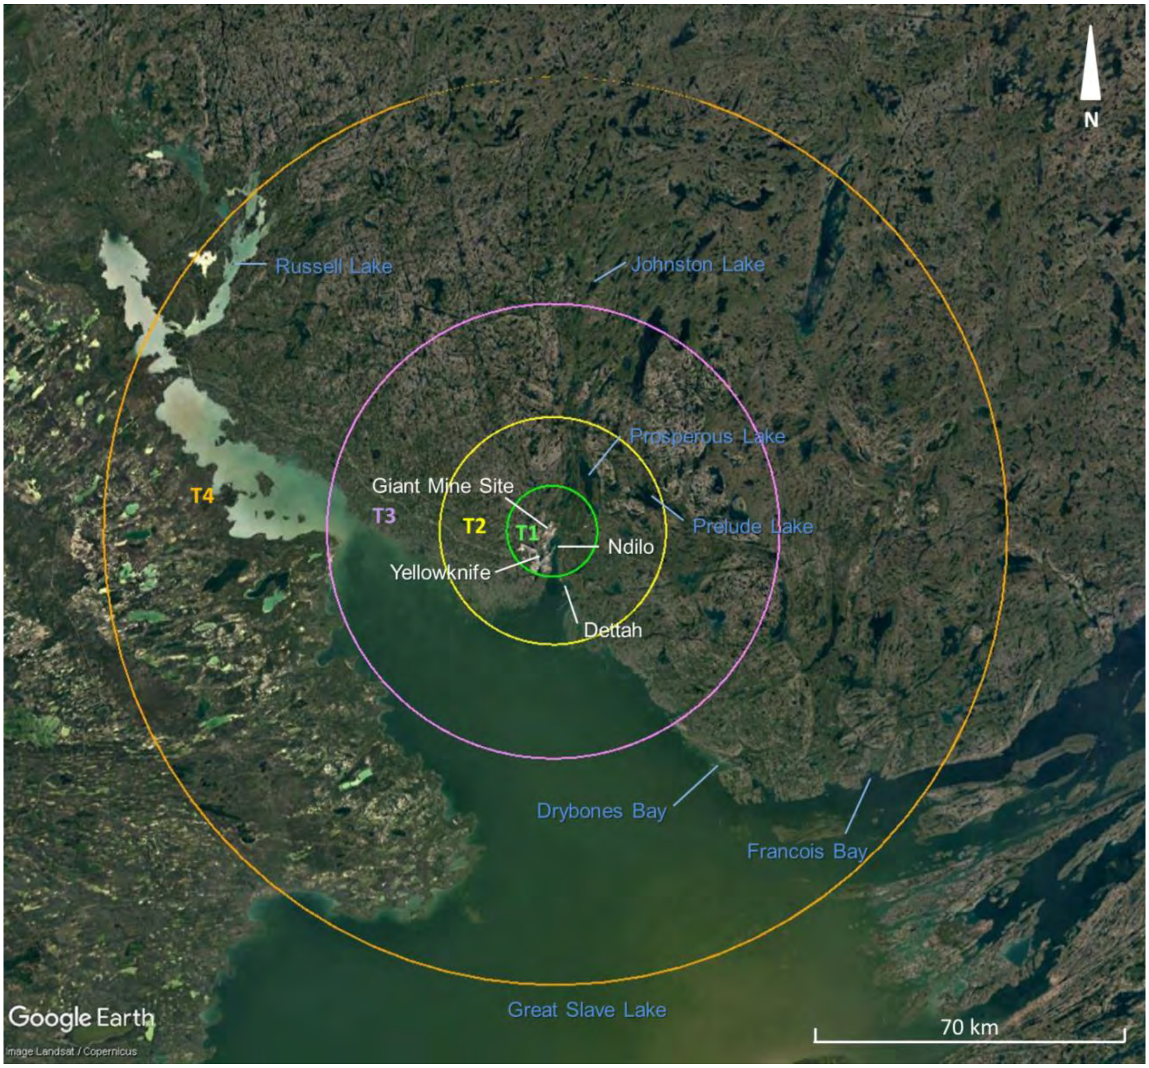
[a] - Based on responses from a few participants who consume caribou.

Hunting/Trapping/Gathering/Fishing Locations

During the three in-person workshops and through the electronic survey, information was collected on which general locations people frequent to hunt, trap, gather, or fish for traditional foods; the findings are summarized below.

The reference map that was used to gather information about where people hunt, trap, and gather terrestrial foods is shown in Figure E.14. Dietary Survey participants were asked to identify general areas where they source their traditional foods from; these areas are shown in Figure E.14 and include T1 (within 10 km from the site), T2 (within 25 km of the site), T3 (within 50 km of the site), T4 (within 100 km from the site), and outside T4 (more than 100 km from the site).

Figure E.14 Hunting/trapping/gathering location reference map



A summary of the locations frequented most often by participants is provided in Table E.3. The few people who reported consuming caribou said the caribou was largely from outside of T4 with an occasional caribou from within T4.

While people reported that most of the moose and Canada goose that they eat are from farther away from the site (i.e., T3 and farther), they reported capturing rabbit, muskrat, beaver, grouse, ptarmigan, and duck from a wider range of distances from the Giant site, including within 10 km from the site in some cases.

The 2017 Dietary Survey found that people do sometimes gather berries, rosehips, Labrador tea, and chives from within 10 km of the Giant Mine site, as these plants are often collected on an opportunistic basis. No participants reported collecting mushrooms from within 10 km from the Giant site.

Table E.3 Summary of most common hunting/trapping/gathering locations

Food Item	Most Frequent Locations	Other Locations
Caribou	Outside of T4	Occasional caribou within T4
Moose	T3, T4 and outside of T4	Occasional moose within T2
Rabbit	T1, T2 and T3	Occasionally rabbit outside of T3
Muskrat	T1, T2 and T3	Occasionally muskrat outside of T3
Beaver	T1, T2 and T3	Occasionally beaver outside of T3
Grouse	T1, T2, and T3	Occasionally grouse outside of T3
Ptarmigan	T1, T2, and T3	Occasionally ptarmigan outside of T3
Duck	T2, T3, and T4	-
Canada Goose	T3,T4, and outsideT4	-
Berries	T2 and T3	Occasionally berries in T1 or outside of T3
Rosehips	T1	-
Labrador Tea	T1, T2, T3, and T4	-
Mushrooms	T2 and T3	Outside of T3
Chives	T1	Occasionally chives in T2

The mapping used to gather information about where people go to fish is shown in Figure E.15. Participants were asked to identify general areas where they fish for different species of fish; these areas include A1 (Yellowknife River Area), A2 (Yellowknife Bay north of Dettah), A3 (Yellowknife Bay south of Dettah), Great Slave Lake beyond Yellowknife Bay, and other regional lakes.

A summary of the locations where participants fish most often is provided in Table E.4. People generally reported fishing for whitefish, lake trout, and northern pike most often from Yellowknife Bay (both north and south of Dettah), but the survey found that these species were obtained from a number of other areas as well. The 2017 Dietary Survey results indicated that most people fishing for inconnu fished in the portion of Yellowknife Bay south of Dettah.

Figure E.15 Fishing location reference map

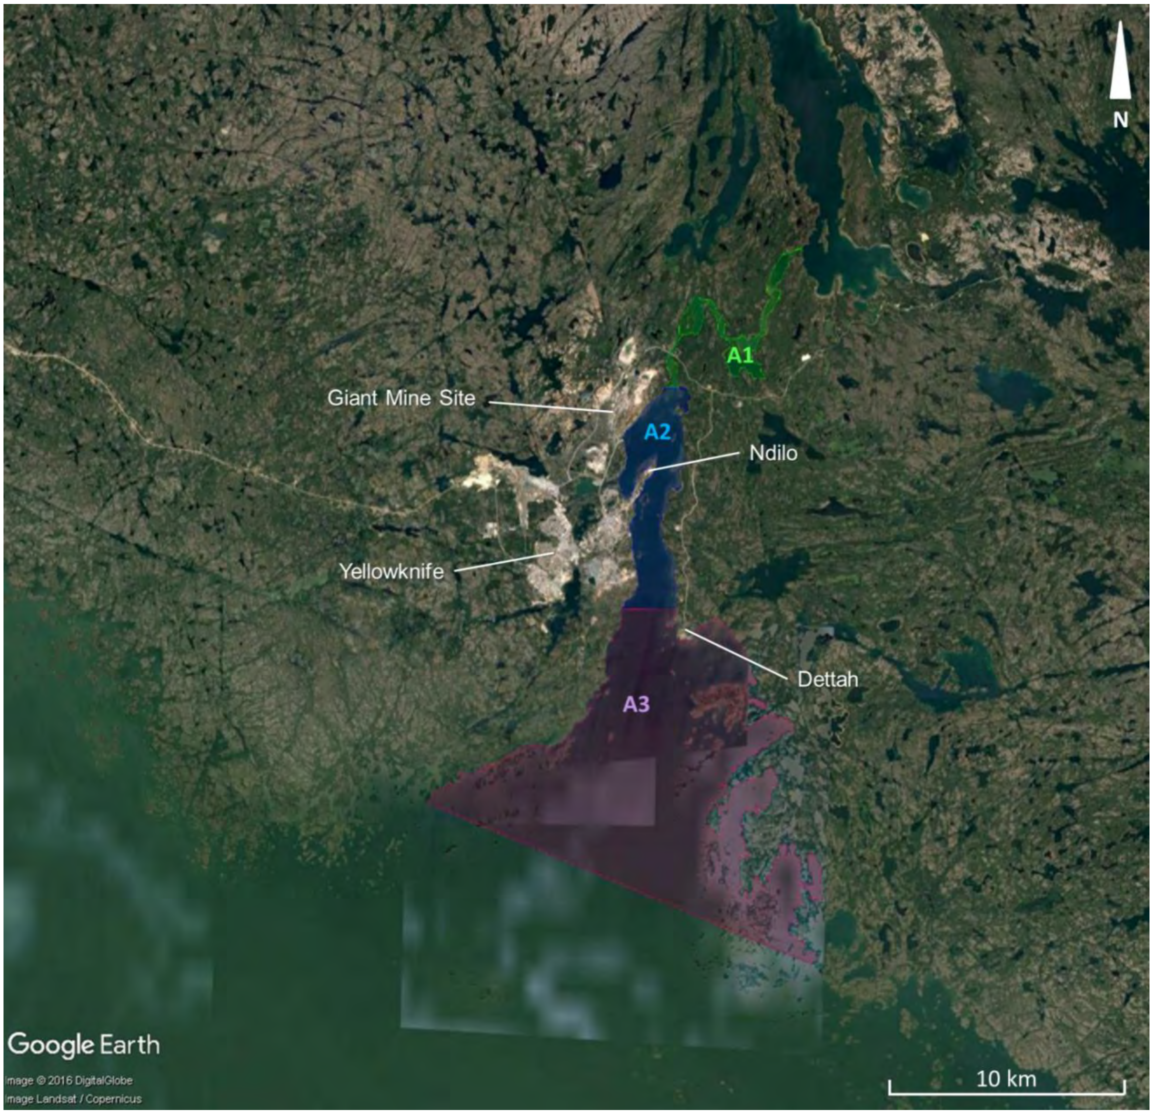


Table E.4 Summary of most common fishing locations

Food Item	Most Frequent Locations	Other Locations
Whitefish	A2, A3	A1, Great Slave Lake beyond A3, and other small regional lakes
Lake Trout	A2, A3	A1, Great Slave Lake beyond A3, and other small regional lakes
Inconnu	A3	Great Slave Lake beyond A3
Northern Pike	A2, A3	A1, Great Slave Lake beyond A3, and other small regional lakes

E.6 Receptor Characteristics

Information on human receptor characteristics are considered, such as body weight, food and drinking water ingestion rates, time spent outside, areas from which food (plants, fish, game) are obtained, etc., in order to complete estimates of potential exposure (Appendix F). Receptor characteristics were based on results from the dietary survey (Section E.5), as well as typical values from relevant guidance documents and other information provided in literature.

E.6.1 Food Consumption

The amount of country food that people reported eating from the survey was characterized for three different diets: a typical country foods eater from the YKDFN, a high country foods eater from the YKDFN, and a country food diet representative of the NSMA community and Yellowknife residents who hunt and fish based on results from the NSMA questionnaire. The assessment also considered people from the different locations that only ate supermarket food. About five people from the YKDFN indicated that they only ate country foods, and these people are captured in the high food diet. The largest number of people reported that they only ate 20% country food, and these people are captured in the typical food diet. A number of elders and young people in their 20s indicated that they either ate only food from the supermarket, or 5 to 10% country foods. The survey also asked people how many portions of different country food they ate based on portions. For all meat and fish, a portion was described as the size of a palm of your hand and was equivalent to 85g. For berries, people were asked about how many handfuls they ate, with a handful being equivalent to ½ c or 50 g. The portions of food and the number of days reported for the three different types of diets are summarized in Table E.5. The types of country food in the table are based on the different food samples collected in the voluntary sampling program.

Table E.5 Characterization of typical diets and adult food ingestion rates of country foods

Food Item	Portions per meal	Meals consumed per year	Portions per year	Ingestion Rate (g/d)[a]
Typical YKDFN				
Moose	2	15	30	7
Fish	2	365	730	170
Rabbit	2	6	12	2.8
Grouse [b]	1	12	12	2.8
Duck	1	10	10	2.3
Muskrat	0.5	8	4	0.9
Beaver	1	4	4	0.9
Goose	2	4	8	1.9
Berries	1	15	15	2.5
Organs - Moose	1	2	2	0.5
High YKDFN				
Moose	3	30	90	21
Fish	3	365	1095	255
Rabbit	3	26	78	18
Grouse [b]	2	20	40	9.3
Duck	3	30	90	21
Muskrat	2	20	40	9.3
Beaver	2	24	48	11.2
Goose	3	8	24	5.6
Berries	1	30	30	4.9
Organs - Moose	1	2	2	0.5
Typical City of Yellowknife				
Moose	1	12	12	2.8
Fish	1	210	210	49
Rabbit	0.5	2	1	0.2
Grouse [b]	1	6	6	1.4
Duck	1	6	6	1.4
Muskrat	0	0	0	0
Beaver	1	2	2	0.5
Goose	1	2	2	0.5
Berries	1	15	15	2.5
Mushrooms	0.5	4	2	0.5
Organs - Moose	1	2	2	0.5

Note: Based on dietary survey results for adults.
[a] – ingestion rates were calculating assuming an 85 g portion size.
[b] – combination of grouse and ptarmigan.

The ingestion rates provided in Table E.5 were specified for adult receptors. Elder receptors were assumed to have the same ingestion rates as adults, while teen, child, and toddler receptors were scaled from adult rates, assuming 91%, 75%, and 50%, respectively. The value for teens is based on data from Richardson (1997) for First Nations people and the values for child and toddler are based on data from a Canada wide survey (Health Canada 1994). Table E.6 provides the derived ingestion rates for the elder, teen, child, and toddler receptors. The survey results indicated that only adults or elders ate organs and mushrooms, and this was considered in the derivation of the rates for the other life stages.

Table E.6 Derived elder, teen, child, and toddler country food ingestion rates

Food Item	Elder [a]	Teen [b]	Child [c]	Toddler [d]
Typical YKDFN (g/d)				
Moose	7.0	6.4	5.2	3.5
Fish	170	155	128	85
Rabbit	2.8	2.5	2.1	1.4
Grouse[e]	2.8	2.5	2.1	1.4
Duck	2.3	2.1	1.7	1.2
Muskrat	0.9	0.8	0.7	0.5
Beaver	0.9	0.8	0.7	0.5
Goose	1.9	1.7	1.4	0.9
Berries	2.5	2.2	1.8	1.2
Organs – Moose [f]	0.5	0	0	0
High YKDFN (g/d)				
Moose	21.0	19.1	15.7	10.5
Fish	255	232	191	128
Rabbit	18.2	16.5	13.6	9.1
Grouse[e]	9.3	8.5	7.0	4.7
Duck	21.0	19.1	15.7	10.5
Muskrat	9.3	8.5	7.0	4.7
Beaver	11.2	10.2	8.4	5.6
Goose	5.6	5.1	4.2	2.8
Berries	4.9	4.5	3.7	2.5
Organs – Moose [f]	0.5	0	0	0
Typical City of Yellowknife (g/d)				
Moose	2.8	2.5	2.1	1.4
Fish	49	45	37	24
Rabbit	0.2	0.2	0.2	0.1
Grouse[e]	1.4	1.3	1.0	0.7
Duck	1.4	1.3	1.0	0.7
Muskrat	0	0	0	0
Beaver	0.5	0.4	0.3	0.2
Goose	0.5	0.4	0.3	0.2
Berries	2.5	2.2	1.8	1.2
Mushrooms [f]	0.5	0	0	0
Organs – Moose [f]	0.5	0	0	0

Note: Based on dietary survey results for adults.
[a] – Assumed equal to adult ingestion rates.
[b] – Assumed 91% of adult ingestion rates.
[c] – Assumed 75% of adult ingestion rates.
[d] – Assumed 50% of adult ingestion rates.
[e] – Combination of grouse and ptarmigan.
[f] – Organs and mushrooms were assumed to not be consumed by teen, child, or toddler receptors.

As part of the sensitivity assessment, consumption of organs from moose, fish, and ptarmigan/grouse was also considered. The dietary survey provided information related to the ingestion of moose organs (see Table E.5); however, there was no information on ingestion rates for fish or ptarmigan/grouse organs from the dietary survey. Therefore, some assumptions were made to derive the ingestion rates presented in Table E.7. Assumptions were based on relative organ to full body mass (with organ weights available from the voluntary sampling data) and applied to the ingestion rates of fish and grouse determined from the dietary survey. This assumes that the organs are consumed at the same relative rate as the meat from the rest of the animal.

Table E.7 Characterization of food ingestion rates of other organs

Food Item	Ingestion Rate (g/d) [a]			Basis of Assumption
	Typical YKDFN	High YKDFN	Typical City of Yellowknife	
Fish Liver	1.7	2.6	0.49	Fish liver is approximately 1% of whole body weight.
Grouse heart	0.06	0.19	0.03	Grouse and ptarmigan heart is approximately 2% of “dressed” whole body weight.
Grouse gizzard and liver	0.14	0.47	0.07	Grouse and ptarmigan gizzard is approximately 3% of “dressed” whole body weight; increased to 5% to account for additional weight of liver.

[a] – For adult and elder receptors only. Calculated based on a percentage of the associated meat ingestion rates for each animal from Table E.5.

E.6.2 Medicinal Tea Intake

A number of assumptions were used to derive appropriate intake rates for medicinal tea. It was assumed that tea was prepared following a ratio of 1 handful of leaves to 1 L of water. A bunch of mint leaves at the supermarket is 90 g; it was assumed that 1 handful is equal to ½ a bunch, or 45 g. This results in a ratio of 45 g to 1 L of water. Following preparation of the tea, it is recommended practice to further dilute the tea to 1/3, prior to consumption. This results in a ratio 15 g leaves to 1 L of water. Tea is typically consumed by the cup, which is approximately 0.25 L. This results in approximately 4 g of leaves per serving of medicinal tea. Based on results of the dietary survey, it was assumed that 3, 52, and 2 servings of Labrador tea were consumed per year for the typical YKDFN, high YKDFN, and typical City of Yellowknife diets, respectively. This equates to medicinal tea intakes of 0.05 g/d, 0.5 g/d, and 0.03 g/d, respectively. Only adult and elder receptors were assumed to drink medicinal tea on a regular basis.

E.6.3 Water Intake

The average water intakes for an adult (20 plus years of age) and elder (70 plus years of age), teen (12 to 19 years of age), child (5 to 11 years of age), and toddler (0.5 to 4 years of age) are provided by Health Canada (2012a) and are 1.5 L/d, 1 L/d, 0.8 L/d, and 0.6 L/d, respectively.

E.6.4 Soil Intake

Soil intake rates are available from Health Canada (2012a). There is uncertainty associated with these values, as they were developed using tracer element mass balance studies that are considered highly variable with numerous sources of uncertainties (Wilson et al. 2013). It is broadly acknowledged among professional risk assessors that the assumed rates of soil ingestion currently used for risk assessment significantly overestimate actual exposure from this environmental medium. Also, the assumptions concerning soil ingestion currently employed and recommended for risk assessment by Health Canada (2012a) are not associated in any way with the amount of time spent in the outdoor environment. As a result, the same assumed rate of soil ingestion is applied whether a hypothetical receptor is assumed to be outdoors for 10 minutes or 10 hours. However, with the exception of children who eat soil (known as pica behaviour), it is logical to expect that the amount of soil ingested, and certainly the likelihood that soil ingestion would actually occur, would be greater if that receptor were outdoors 10 hours versus 10 minutes and will not occur immediately after the person goes outdoors.

Wilson et al. (2013) adopted a mechanistic hand-loading and transfer approach to derive revised soil ingestion rates using both deterministic and probabilistic methods, and adapted it specifically for the Canadian context using the age groups and receptor characteristics supported by Health Canada (2012a). These soil ingestion rates are derived separately than dust ingestion rates and can be developed into an hourly rate or adjusted on a site-specific basis. For this assessment, the deterministic estimates of soil ingestion rates from Wilson et al. (2013) were used, with average values for the elder, adult, teen, child, and toddler of 1.5 mg/d, 1.6 mg/d, 1.4 mg/d, 21 mg/d, and 14 mg/d, respectively. These soil ingestion rates are physically based and more intuitive than tracer element mass balance studies and account for the important fact that soil exposure is time dependant and separate to dust ingestion.

E.6.5 Indoor Dust Intake

The soil intake rates from Health Canada (2012a) also implicitly include indoor dust ingestion and, in many risk assessments, dust ingestion rates were assumed to be the same as soil ingestion rates. Wilson et al. (2013) determined separate indoor dust ingestion rates using a mechanistic hand-loading and transfer approach. Indoor dust rates were determined both deterministically and probabilistically. Wilson et al. (2013) adapted the approach used by the Contaminants of Potential Concern Committee of The World Trade Center Indoor Air Task Force Working Group (WTCWG 2003) using data more representative of the Canadian context. The dust ingestion rates were dependent on whether an individual was in contact with hard surfaces such as hardwood, linoleum, tiles, countertops, tables and window sills or soft surfaces such as carpets and rugs, sofas and beds. It was assumed that, in a typical home, 50% of the surfaces are hard surfaces and the other 50% are soft surfaces. For this assessment, the deterministic estimates of dust ingestion rates from Wilson et al. (2013) were used, with average values for the elder, adult, teen, child, and toddler of 2.5 mg/d, 2.5 mg/d, 2.2 mg/d, 31 mg/d, and 41 mg/d, respectively.

E.6.6 Sediment Intake

The estimated sediment ingestion rates from the literature for use in human health risk assessments are limited. In historical human health risk assessments, soil ingestion rates were used as a surrogate for sediment ingestion rates. However, it is not clear whether the use of soil ingestion as a surrogate is a conservative assumption, since, on the one hand, the soil exposures are expected to have higher durations than sediment, but, on the other hand, sediment has a greater adherence to skin (Wilson Scientific and Meridian 2011).

Wilson Scientific and Meridian (2011, 2012), in contractor reports to Health Canada's Contaminated Sites Division, developed central tendency sediment ingestion rates of 78 mg/d, 25 mg/d, and 28 mg/d for the child, teen, and adult, respectively, based on an analysis of estimated intakes from hand-to-mouth contact with sediment and incidental ingestion of water containing sediment (Wilson Scientific and Meridian 2011). In a follow-up report, Wilson Scientific and Meridian (2012) proposed average sediment ingestion rates of 90 mg/d to 120 mg/d for the child and 30 mg/d to 40 mg/d for the teen and adult. Additionally, they proposed mean sediment ingestion rates during in-water activities of 10 mg/d to 20 mg/d for all age categories for contact with suspended sediment. The authors recommended that the high end of these ranges be used for beaches, tidal flats, and riverbeds that are known to be used regularly by the general public.

Wilson et al. (2015) provided sediment ingestion rates based on hourly exposure to allow for the adjustment of the number of hours in contact with sediment as that time is expected to be highly variable depending on the location. The following rates of 72 mg/hr, 57 mg/hr, 18 mg/hr, and 20 mg/hr are provided for hand-to-mouth contact for the toddler, child, teen, and adult, respectively. This ingestion rate is only relevant for on-land activities such as playing in the sand on a beach where sediment is exposed. They also provide a suspended sediment ingestion rate of 7.7 mg/hr for all age groups for near-shore, in-water activities in shallow water (e.g., wading, walking, and playing in water).

E.6.7 Swimming Water Intake

Limited information related to the incidental ingestion of water while swimming is available. The U.S. EPA (2011) provides an estimate of ingestion of water while swimming for an adult and child from on a quantitative study by Dufour et al. (2006), based on results from swimming pool experiments. Dufour et al. (2006) considered that swimming behaviour of recreational pool swimmers may be similar to freshwater swimmers. Based on the information in U.S. EPA (2011), the mean hourly rate of 21 mL/hr for an adult was used for the adult, elder, and teen receptors, and the mean hourly rate of 49 mL/hr for a child was used for the child and toddler receptors.

The Chicago School of Public Health (Dorevitch et al. 2011) carried out a study of water ingestion during recreational activities. This study indicated that the upper confidence estimate of swimming activities was 35 mL/hr which is similar to the average of the adult and child ingestion rates provided by the U.S. EPA (2011).

The World Health Organization (WHO 2006) indicates that the amount of water ingested by swimmers and pool users depends on a range of factors, including experience, age, skill, and type of activity. The WHO (2006) indicates that a number of estimates have been made of possible intakes for children while participating in activities in swimming pools and similar environments, and indicates that the most convincing study was a pilot study by Evans et al. (2001). This study found that the average water intake by children (37 mL) was higher than the intake by adults (16 mL). In addition, the intake by adult men (22 mL) was higher than that by women (12 mL) and the intake by boys (45 mL) was higher than girls (30 mL). The upper 95th percentile intake for children was approximately 90 mL/d and therefore the WHO (2006) used a 'worst case' intake of 100 mL/d for a child.

In the guidelines for *Canadian Recreational Water Quality*, Health Canada (2012b) use an incidental water ingestion rate of 250 mL/d for a child. Health Canada indicates that this value is likely a conservative estimate of the incidental water ingestion rate and base their value on studies from the WHO (2003) and Evans et al. (2006). However, the WHO (2003) indicates that a swimmer with whole body contact can expect to ingest 100 mL/d to 200 mL/d during swimming.

Given this information, an uncertainty analysis was conducted with an incidental ingestion of 100 mL/d and 250 mL/d for a toddler and child and 50 mL/d for an adult.

E.6.8 Dermal Contact

Soil

Intake of COPC can occur *via* dermal contact with contaminated soil. Exposed skin surface area quantities for hands for the adult, teen, child, and toddler of 890 cm^2, 800 cm^2, 590 cm^2, and 430 cm^2, respectively, were obtained from Health Canada (2010). Exposed skin surface area quantities for arms and legs for the elder and adult, teen, child, and toddler of 8,220 cm^2, 7,200 cm^2, 4,550 cm^2, and 2,580 cm^2, respectively, were obtained from Health Canada (2012a). It is not considered appropriate to use the total body surface area for the calculation of intake from soil via dermal contact, since clothes provide protection to other areas of the body.

Single point estimates for soil loading to exposed skin (hands and arms and legs) were obtained from Health Canada (2012a); these values are 1 x 10^{-7} kg/cm^2-event for hands and 1 x 10^{-8} kg/cm^2-event for arms and legs. Soil loading rates for dermal exposure were calculated using equation (E-1). For dermal exposures, it is typically assumed that one event occurs each day of exposure.

$$DLR_{soil} = \left(SA_{hands} \times SL_{hands} + SA_{arms+legs} \times SL_{other}\right) \times \frac{1\ event}{d} \qquad \text{(E-1)}$$

Where:

DLR_{soil}	=	Dermal loading rate for soil (kg/d)
SA_{hands}	=	Surface area – hands (cm^2)
SL_{hands}	=	Soil loading – hands (kg/cm^2/event)
$SA_{arms+legs}$	=	Surface area – arms and legs (cm^2)
SL_{other}	=	Soil loading – other (kg/cm^2/event)

Dust

Similarly, intake of COPC can occur *via* dermal contact with indoor dust. Exposed skin surface areas for hands for the adult, teen, child, and toddler of 890 cm^2, 800 cm^2, 590 cm^2, and 430 cm^2, respectively, were obtained from Health Canada (2010). Indoor dust exposure was considered to occur through contact with hands, since clothes provide protection to other areas of the body and hands are the most likely to be in contact with indoor dust.

Single point estimates for soil loading to exposed skin (hands) were obtained from Health Canada (2011); this value is 2 x 10^{-7} kg/cm^2-event for hands. Dust loading rates for dermal exposure were calculated using equation (E-2). For dermal exposures, it is typically assumed that 1 event occurs each day of exposure.

$$DLR_{dust} = (SA_{hands} \times SL_{hands}) \times \frac{1\ event}{d} \tag{E-2}$$

Where:

DLR_{dust} = Dermal loading rate for dust (kg/d)
SA_{hands} = Surface area – hands (cm^2)
SL_{hands} = Soil loading – hands (kg/cm^2/event)

Sediment

In order to calculate exposure to contaminants in sediment via dermal contact, it is necessary to estimate the amount of sediment that adheres to the skin, known as sediment loading or sediment adherence. It should be noted that sediments that are underwater are likely to be washed off while wading in water, whereas wet sediments at the shoreline are likely to adhere to the skin. As with sediment ingestion, information on soil adherence has generally been used for sediment adherence.

For soil adherence to skin, Health Canada (2012a) Guidance on Human Health Preliminary Quantitative Risk Assessment recommends 0.1 mg/cm^2 /event for hands and 0.01 mg/cm^2/event for the rest of the body based on soil studies by Kissel et al. (1996, 1998).

Since wet soil is roughly similar to sediment, U.S. EPA (2004) guidance for dermal risk assessment recommends 0.2 mg/cm^2/day (geometric mean) based on studies of children playing with toys in wet soil (Kissel et al. 1998). For adult gardeners over 16 years old, the U.S. EPA (2004) recommends a soil adherence rate of 0.07 mg/cm^2/day (geometric mean).

For the child playing in sediment, the U.S. EPA's *Exposure Factors Handbook* (U.S. EPA 2011) recommends adherence factors of 0.04 to 21 mg/cm^2 based on geometric means of children 7 to 12 years old playing in tidal flats (Shoaf et al. 2005a), depending on the body part exposed. For the adult engaged in outdoor sports or activities with soil, the U.S. EPA (2011) recommends 0.03 mg/cm^2 to 0.16 mg/cm^2 (based on geometric means from Kissel et al. (1996) and Holmes et al. (1999). Shoaf et al. (2005b) provides adherence factors for adults clam digging on tidal flats, and adherence factors ranged from 0.02 mg/cm^2 to 0.88 mg/cm^2 based on geometric means.

As seen from the above discussion, the sediment adherence factors are as much as two orders of magnitude higher than the soil adherence factors. However, there is some evidence that, as the soil adherence increases over a certain critical level, which is equivalent to a monolayer on the skin, the fraction of the contaminant absorbed decreases (U.S. EPA 1998). While the level of loading equal to the monolayer has not been well established, the Massachusetts Department of Environmental Protection (MassDEP 2002) recommended a sediment adherence factor of 1 mg/cm^2 as the best estimate of sediment adherence corresponding to a monolayer of most sediment types. They reported that a high adherence factor of 22 mg/cm^2 is not a reasonable value to use, as it may substantially overestimate the dose of contaminant received from dermal contact with sediment. Therefore, the value of 1 mg/cm^2 was used in the assessment.

The Ontario Ministry of the Environment and Climate Change (MOECC 2014) developed sediment adherence factors which were weighted by body part and by season. The adherence factors selected for the child were based on a study by Shoaf et al. (2005a) of children playing in tidal flats. Adherence factors for the adult were selected as the higher of adults engaged in outdoor sports and adults engaged in activities with soil from the U.S. EPA *Exposure Factors Handbook* (U.S. EPA 2011). The teen was assumed to have the same adherence factors as the adult. This resulted in time-weighted adherence factors of 1.19 mg/cm^2, 0.11 mg/cm^2 and 0.11 mg/cm^2 for the child, teen and adult, respectively, for annual exposure. For exposure during the summer months, the weighted average was 3.85 mg/cm^2, 0.11 mg/cm^2, and 0.11 mg/cm^2 for the child teen and adult, respectively.

The Michigan Department of Community Health (2012), in co-operation with the Agency for Toxic Substances and Disease Registry, in evaluating the effects of an oil spill into the Kalamazoo River used a weighted sediment adherence factor of 2.98 mg/cm^2 for a child (ages 1 to 6) based on the study by Shoaf et al. (2005a). This assumed that children were wading in the river or damp shoreline and sediment would not have been washed off from contact with water. For adults, a soil adherence factor of 0.3 mg/cm^2 was used, which was from a study of adults working in a garden (MDEQ 2001).

For the current assessment, a weighted sediment adherence factor for skin for all life stages was used based on Shoaf et al. (2005a) for children and Shoaf et al. (2005b) for adults. The MADEP (2002) recommended sediment adherence factor for feet of 1 mg/cm^2 was used for the adult and child. Full body (hands, arms, legs, feet) exposure was considered for toddlers, while children were assumed to have feet and leg exposure. Teens, adults, and elders were assumed to have sediment exposure to feet, only.

Table E.8 Weighted sediment adherence factors for skin

Parameter	Toddler	Child	Teen	Adult
AF hands (mg/cm^2)	0.49	-	-	-
SA hands (cm^2)	430	-	-	-
AF forearms (mg/cm^2)	0.17	-	-	-
SA forearms (cm^2)	450	-	-	-
AF legs (mg/cm^2)	0.7	0.7	-	-
SA legs (cm^2)	1690	3070	-	-
AF feet (mg/cm^2)	1	1	0.58	0.58
SA feet (cm^2)	430	720	1080	1190
Total SA (cm^2)	3000	3790	1080	1190
Weighted average AF (mg/cm^2)	0.63	0.76	0.58	0.58
Weighted average AF (kg/cm^2)	6.3×10^{-7}	7.6×10^{-7}	5.8×10^{-7}	5.8×10^{-7}

Note: Based of Shoaf et al. (2005a) for children and Shoaf et al. (2005b) for adults. AF for feet for adult and child based on MADEP (2002).
Assumed forearms 50% of total arms. Feet surface area obtained from Richardson (1997). Other surface area values obtained from Health Canada (2012a).

The weighted sediment adherence factors in Table E.8 were used with the associated skin surface area assumed for each receptor to calculate sediment loading rates for dermal exposure, as shown in equation (E-3).

$$DLR_{sed} = SA \times AF_{sed} \tag{E-3}$$

Where:

DLR_{sed} = Dermal loading rate for sediment (kg/d)

SA	=	Surface area assumed for sediment exposure, see text (cm^2)
AF_{sed}	=	Weighted average sediment adherence factor (kg/cm^2)

Swimming Water

Intake of COPC can occur *via* dermal contact with surface water while swimming. Exposed skin surface area quantities for total body for the adult, teen, child, and toddler of 17640 cm^2, 15470 cm^2, 10140 cm^2, and 6130 cm^2, respectively, were obtained from Health Canada (2010).

For dermal exposures with water, a COPC-specific dermal permeability coefficient K_p in water is considered. For this assessment, all COPC have a K_p of $1x10^{-3}$ cm/hr, based on U.S. EPA (2004). Water loading rates for dermal exposure while swimming were calculated using equation (E-4).

$$DLR_{swimming} = \left(SA_{body} \times K_p\right) \times CF \qquad \text{(E-4)}$$

Where:

$DLR_{swimming}$	=	Dermal loading rate for swimming water (L/hr)
SA_{body}	=	Surface area – total body (cm^2)
K_p	=	Dermal permeability coefficient (cm/hr)
CF	=	Conversion factor – 1000 L/m^3 x $1m^3/100^3$ cm^3

E.6.9 Body Weight

The body weights (bw) of a toddler, child, teen and adult are needed to calculate daily intake rates (mg/(kg (bw) d)). For this assessment, the body weights used for the adult, teen, child, and toddler were 70.7 kg, 59.7 kg, 32.9 kg, and 16.5 kg, respectively (Health Canada 2010).

E.6.10 Summary of Receptor Characteristics

Intake rates of food were presented in Section E.6.1. Table E.9 provides a summary of the other (non-food) receptor characteristics for the toddler, child, teen, adult, and elder receptors selected for the assessment.

Table E.9 Summary of selected human receptor characteristics

Receptor Characteristic	Receptor				
	Toddler	Child	Teen	Adult	Elder
Water (L/d)	0.6	0.8	1.0	1.5	1.5
Soil Intake (mg dw/d)	14	21	1.4	1.6	1.5
Indoor Dust Intake (mg dw/d)	41	31	2.2	2.5	2.5
Sediment Intake – Wading (mg dw/hr)	7.7	7.7	7.7	7.7	7.7
Sediment Intake – Beach (mg dw/hr)	72	57	18	20	20
Soil Dermal Loading Rate (kg/d)	6.9×10^{-5}	1.1×10^{-4}	1.5×10^{-4}	1.7×10^{-4}	1.7×10^{-4}
Indoor Dust Dermal Loading Rate (kg/d)	8.6×10^{-5}	1.2×10^{-4}	1.6×10^{-4}	1.8×10^{-4}	1.8×10^{-4}
Sediment Dermal Loading Rate (kg/d)	1.7×10^{-3}	2.2×10^{-3}	6.3×10^{-4}	7.0×10^{-4}	7.0×10^{-4}
Body Weight (kg)	16.5	32.9	59.7	70.7	70.7

Notes: Food intake rates and medicinal tea intake rates are provided separately in Section E.6.1 and E.6.2, respectively.

E.7 Supermarket Intakes

Intakes of COPC from supermarket foods were considered for receptors with typical country and typical city diets as well as for the supermarket foods only receptors. Receptors with high country diets were assumed to not have additional intakes from supermarket foods.

Typical intakes of COPC from supermarket foods were obtained from literature and are presented in Table E.10. Canadian references were preferred; however, for antimony, references from other jurisdictions were considered in order to reduce double-counting of antimony intake from meat, as well as to incorporate more recent information. Health Canada (1979) does provide an estimate of antimony intake through food, although it is based on a United States study (ATSDR 1992). A more recent study from the United Kingdom (FSA 2009) provides information on food concentrations and intakes for antimony, and this study was selected for use in the assessment.

Table E.10 Summary of general Canadian supermarket food dietary intakes

Constituent	Intake (mg/kg-d)				Reference
	Adult/Elder	Teen	Child	Toddler	
Antimony	3.3×10^{-5}	5.0×10^{-5}	5.0×10^{-5}	7.7×10^{-5}	FSA (2009), with consideration of information presented in Health Canada (1979).
Arsenic	8.0×10^{-5}	1.0×10^{-4}	2.0×10^{-4}	3.0×10^{-4}	EC (1999), inorganic arsenic in food.
Manganese	0.056	0.059	0.087	0.11	Health Canada (2011).

Note: FSA –Food Standards Agency, EC – Environment Canada.

E.8 Exposure Frequency and Duration

The exposure assessment considers the frequency and duration of exposures to the various receptors via the pathways identified above. Exposure frequency refers to the frequency that a receptor experiences an exposure via a particular pathway, while exposure duration refers to the amount of time over the year that the behaviour occurs. The following sections provide the rationale for the exposure frequency and duration assumptions used in the assessment.

E.8.1 Food, Water, and Tea Exposure Frequency

The assessment considered exposure to food, drinking water, and medicinal for 7 days per week, 52 weeks per year. In most cases, country foods were assumed to be obtained from one location; however, two different locations were considered for fish and berries. For example for Ndilo and Dettah, people were assumed to get 10% of fish from North Yellowknife Bay and 90% of fish from South Yellowknife Bay. This was based on the findings from the dietary survey in 2012 that indicated that some people had some nets in North Yellowknife Bay. For berries, a concern was noted for children eating berries in Ndilo. As there were not enough berries in Ndilo to support the amount of berries being consumed, it was assumed that 5% of berries were obtained from Ndilo and the other 95% of berries came from areas more than 10 km from the Giant Mine, where most people go to gather berries.

Results from the dietary survey (Section E.5) were used to designate the areas where fish and berries were obtained for each receptor location. These assumptions are outlined in Table E.11.

Table E.11 Exposure assumptions for fish and berries

Food	Location	Fraction of Diet					
		Dettah	Ndilo	Latham Island	City of Yellowknife	Ingraham Trail	Townsite
Fish	North Yellowknife Bay (A2)	0.1	0.1	0	0	0	0
	South Yellowknife Bay (A3)	0.9	0.9	1	1	1	1
Berry	Ndilo	0	0.05	0	0	0	0
	Within 10 km of Giant Mine (T1 incl. Ndilo)	0	0	0.05	0	0	0
	Beyond 10 km of Giant Mine	1	0.95	0.95	1	1	1

Note: Fish and berry locations based on dietary survey results.

E.8.2 Soil Exposure Frequency

For outdoor soils, such as those that would occur outside a home, the exposure frequency was assumed to be four months (May to September), which represents the time when the soil is considered to be accessible. This translated into an exposure frequency of 5 days per week, 16 weeks per year. As mentioned in Section E.6.7, dermal exposures were assumed to occur one event per day of exposure.

Recreational soil exposures, such as from hiking, were assumed to occur on the weekend during the summer months, or for 2 days a week, 10 weeks a year. Half a day of soil ingestion was considered for the recreational soil exposures. Similar to outdoor soils, dermal exposures were assumed to occur one event per day of exposure.

For scenarios with recreational soil exposures, half a day of soil ingestion was considered during recreational soil activities, while an additional day of soil ingestion was considered from outdoor (outside a home) activities. This leads to a slight double counting for the soil ingestion pathway, since a day and a half of soil ingestion is considered. Similar for dermal exposures, on days with recreational soil activities, exposures from both the outdoor (outside a home) activities as well as recreational soil activities are considered (essentially nine days of soil exposure in a week). These assumptions lead to an overestimate of exposures for the recreational soil scenarios.

E.8.3 Indoor Dust Exposure Frequency

It was assumed that exposure to indoor dust would occur 7 days a week, 52 weeks a year. As mentioned in Section E.6.7, dermal exposures were assumed to occur one event per day of exposure.

E.8.4 Sediment Exposure Frequency

It was assumed that people would wade or visit the beach at Long Lake about 10 weeks year, or when the water is warm enough to wade. Wading was assumed to occur for 2 hours per day, 7 days per week, during the warmer weather.

E.8.5 Swimming Exposure Frequency

It was assumed that people would swim at Long Lake about 10 weeks year, or when the water is warm enough to swim. Swimming was assumed to occur for 1 hour per day, 3 days per week, during the warmer weather and in conjunction with wading, as described above.

E.8.6 Averaging Periods

Exposure is averaged over an averaging period, which is representative of the exposure frequency and duration. For the food, water, tea, and indoor dust exposure pathways, the averaging period was selected to be 52 weeks per year, consistent with the exposure frequency assumed for these pathways. In the current assessment, although exposures to soil and sediment are assumed to occur seasonally, exposure is consistent throughout the season, as opposed to periodic or at defined intervals over the course of the year. Therefore, for these pathways, the averaging period was selected to be consistent with the exposure frequency, or 16 weeks per year for outdoor soil, 10 weeks per year for recreational soil, sediment, and swimming exposures. This ensures that the exposures via these pathways are not underestimated.

E.8.7 Exposure Durations

For the consideration of potential effects from carcinogenic COPC, the various durations of exposure for each life stage were considered in order to estimate a lifetime risk to a receptor from exposure over their lifetime. A lifetime receptor was calculated assuming 4 years as a toddler, 6 years as a child, 8 years as a teen, 52 years as an adult, and 10 years as an elder, for a total of 80 years of exposure.

E.9 Exposure Scenarios and Sensitivity Assessments

Various exposure scenarios were considered for the human receptors selected for the assessment. Table E.12 provides a summary of the various exposure scenarios considered for each location.

Everyone was assumed in the base case exposure scenario to get their drinking water from the municipal source and to be exposed where they live to concentrations in the air, soil, and indoor dust. Thus, this scenario captures the unique exposure in their areas. Members of the YKDFN community (Ndilo and Dettah) were assumed to have either a purely supermarket food diet, a typical country food diet that is also supplemented with supermarket food, or a high country food diet. People in the City of Yellowknife were assumed to have a purely supermarket food diet. In addition, because the Metis community also lives there and has some avid hunters and fishers, it was assumed that people in Yellowknife would also eat some country food as well as supermarket food. It was assumed that the Ingraham Trail and Latham Island resident would also have a similar country food diet to the City of Yellowknife. An unrealistic scenario was also evaluated where it was assumed that someone with a typical country food diet was living at the former Townsite. This scenario is used to demonstrate the impact of the remedial actions on the former Townsite location.

Table E.12 also indicates the various additional assessments that were completed for each exposure scenario. In addition to the consumption of food based on the indicated diets, the additional assessments considered the following:

- Ingestion of medicinal tea for adults and elders.
- Ingestion of mushrooms for adults and elders only in City of Yellowknife as the Metis community indicated that they ate mushrooms.
- Ingestion of drinking water from South Yellowknife Bay (for Dettah receptors), North Yellowknife Bay (for Ndilo receptors), and Back Bay (for Latham Island receptors).
- Ingestion of organs (moose, fish liver, ptarmigan/grouse heart, and ptarmigan/grouse gizzards and liver) for adults and elders.
- Wading in near-shore sediments of South Yellowknife Bay (for Dettah receptors), North Yellowknife Bay (for Ndilo receptors), Back Bay (for Latham Island receptors), Long Lake (for City of Yellowknife receptors), and Giant Townsite (for the hypothetical Townsite receptors).

- Visiting the beach at Long Lake for the City of Yellowknife receptors.
- Swimming at Long Lake for the City of Yellowknife receptors.
- Recreational use of the Giant Mine, including berry collection, for the hypothetical current Townsite receptors. This scenario was evaluated to demonstrate the differences between current exposures and future exposures at the former Townsite after remedial activities have occurred.

The results for these exposure scenarios are provided in Appendix H.

The objective of the risk assessment is to determine what the effects of the remedial activities at the Giant Mine will have on the residents in the vicinity of the site. The remedial actions at the site involve the capping of the tailings, the remediation of arsenic concentrations in the disturbed areas of the site to the GNWT Industrial Criterion, the fencing of areas with arsenic concentrations above 3000 mg/kg, and moving the water treatment discharge pipe to near the mouth of Baker Creek. These remedial activities will not have any effect on the unique location exposures that were evaluated in the base case. In addition, remedial activities will not impact the concentrations in the country foods, as none of the samples were obtained from the Giant Mine. The remedial activities will allow access to the Giant Mine for recreational activities such as walking, running, cycling etc., and this exposure was evaluated in the future scenario. The effect of the treated water discharge near the mouth of Baker Creek was evaluated using modelling to determine what the water and sediment concentrations would be in Back Bay and North Yellowknife Bay. Thus, a future scenario involved drinking water from North Yellowknife Bay.

Table E.12 Summary of exposure scenarios for HHRA – current conditions

Location	Diet	Additional Assessments							
		Medicinal Tea	Mushroom	Drinking Water	Organs	Wading	Swimming at Long Lake	Beach at Long Lake	Recreational Use of Giant Mine (including Berry Collection)
Dettah	Typical YKDFN	x	o	x	x	x	o	o	o
	High YKDFN	x	o	o	x	o	o	o	o
	Supermarket	o	o	o	o	o	o	o	o
Ndilo	Typical YKDFN	x	o	x	x	x	o	o	o
	High YKDFN	x	o	o	x	o	o	o	o
	Supermarket	o	o	o	o	o	o	o	o
Latham Island	Typical City of Yellowknife	x	o	x	x	x	o	o	o
	Supermarket	o	o	o	o	o	o	o	o
City of Yellowknife	Typical NSMA	x	x	o	x	x	x	x	o
	Supermarket	o	o	o	o	o	o	o	o
Ingraham Trail	Typical City of Yellowknife	x	o	o	x	o	o	o	o
Townsite	Typical City of Yellowknife	o	o	o	o	x	o	o	x

x – Scenario completed. o – Scenario not assessed.

Based on the results (Appendix H) for the scenarios considered for current conditions (Table E.12), scenarios were determined to assess future conditions following planned remediation activities at the site. Since the Dettah, Ingraham Trail, and Latham Island receptors were shown to have lower and similar exposures, respectively, compared with the Ndilo receptors, the assessment of future conditions focused on Ndilo receptors, as well as City of Yellowknife and future Townsite receptors. It was assumed that people in Ndilo would spend some time on the Giant Mine doing recreational activities. It was also assumed that, while they were on the site, they may pick some berries if they were in season (assumed to be 5% of total berry consumption). An evaluation of a City of Yellowknife resident spending time at the Giant Mine for recreational activities was also evaluated, including 5% of berry consumption from the Giant Mine.

At the former Townsite and marina, the remedial actions involve clean-up of the soils to the arsenic GNWT residential criterion. No plans have been made for the final land use in this area; however, the risk assessment has evaluated the strictest land use where someone would live in this area. The scenarios and additional assessments completed for future conditions are outlined in Table E.13.

Table E.13 Summary of exposure scenarios for HHRA – future conditions

Location	Diet	Assessments	
		Wading	Recreational Use of Giant Mine (including Berry Collection)
Ndilo	Typical YKDFN	x	x
City of Yellowknife	Typical NSMA	o	x
Townsite	Typical City of Yellowknife	x	x

x – Scenario completed. o – Scenario not assessed.

E.9.1 Sensitivity Assessment

A number of assumptions have gone into the risk assessment in order to evaluate realistic, yet conservative, estimates of exposure. A few sensitivity assessments were carried out to see the effect of some of these assumptions on the results.

The first sensitivity analysis was related to country food concentrations. An average value for the samples was used to reflect what people would eat food from a wide variety of areas. To determine whether this assumption was realistic or not and would result in a substantial change in the results, a sensitivity assessment was completed using the maximum measured concentrations for the country foods.

In the risk assessment, it was assumed that 5% of berries for the people living in Ndilo came from the community to account for the fact that children have been reported eating berries from bushes around Ndilo. Although it is unlikely to occur, since there are not enough berry bushes to support this, a sensitivity assessment was completed to evaluate the consumption of 100% of berries from Ndilo.

One moose sample obtained from the voluntary sampling had an arsenic level of 0.65 mg/kg wet weight and was obtained from a shoulder blade sample with very little meat on it. The meat was scraped off the bone and, therefore, this sample is likely not representative of meat but is more indicative of levels in the bone. In addition, the concentration of arsenic in moose liver collected from the area is much lower than this measured concentration. However, since moose represents the most consumed meat from the 2017 Dietary Survey Update and to ensure that potential risks were not being misrepresented, a sensitivity assessment was completed using the arsenic concentration of 0.65 mg/kg wet weight from this moose sample.

The concentration or arsenic in ptarmigan was an order of magnitude higher than concentrations measured in background (0.02 mg/kg ww vs. 0.004 mg/kg ww). Therefore, the sensitivity analysis considered that ptarmigan/grouse made up all the wild game that people ate.

Although the assumption of indoor dust equal to 70% outdoor soil concentrations is an accepted practice, a sensitivity assessment was completed to address the uncertainty around this assumption. An assessment was completed to illustrate the potential exposures assuming that indoor dust is equal to (or 100% of) outdoor soil concentrations.

An additional uncertainty involved the arsenic bioaccessibility in animals. A value of 50% was used based on the measurements in hare in Yellowknife from a study by Koch et al. (2013). The sensitivity assessment looked at the consideration of 100% bioaccessibility of arsenic in animals, even though it is well known that arsenic in food samples are not 100% available.

There have been several “hot spots” identified in soils in the community of Ndilo. The sensitivity analysis evaluated the impact of cleaning up the three highest “hot spots” in the Ndilo community.

It is very difficult to quantify the effects of climate change in the future. In the Developer’s Assessment Report (DAR; INAC/GNWT 2010), the Canadian Climate Change Scenarios Network (CCCSN) assessment indicated that precipitation may increase by up to 15% over the next 50 years. As the future assessment was evaluating a 100 year scenario, it was assumed the change in precipitation could be as high as 30%. The increased precipitation could lead to increased run-off and soil erosion, with a subsequent increase in environmental concentrations. In an attempt to evaluate this effect, the sensitivity assessment looked at the effect of increasing the water and sediment concentrations and, consequently, fish concentrations by 30%.

ATTACHMENT E.1

QUESTIONNAIRE FOR 2017 DIETARY SURVEY WORKSHOPS

APPENDIX E – ATTACHMENT 1: QUESTIONNAIRE FOR 2017 DIETARY SURVEY WORKSHOPS

Workshop Questionnaire for January 17th and 18th, 2017 Workshops

Caribou

Previous information collected in your community showed that 89% of people from Ndilo and Dettah ate caribou 4 days a week. Now that caribou is not available, what do you eat instead? Other foods such as moose, fish? Store-bought food? A mixture of store-bought and traditional food?

Serving size – 85g or 3 oz

Moose

From our discussions in the community, moose is hunted mainly in the fall but can also be hunted any time if you see one. Previous information collected showed that about half of people from Ndilo and Dettah ate this much moose meat 1 day every three weeks or about 17 times a year.

How often do you eat moose in the fall (every day, 2 to 4 days a week; once a week)? What about other times of the year (once every 2 weeks, once every 3 weeks)? Do you eat this much meat at a meal? or would you eat this much over several meals in a day? How much would you eat if you ate less or more? How about children how much would they generally eat? Where are you most likely to go to hunt for moose?

How many of you eat moose liver? The previous study said that about a quarter of people from Ndilo and Dettah ate moose liver 1 day every 5 weeks or about 10 times a year. Is this how many times you would eat in the fall? Would you eat more than 10 times a year? How much? One person ate this much moose liver in a day. Would you eat more liver/ how much? How about less liver/how much? What about children how much would they generally eat?

What about moose heart? How much do you eat and how often? What about children. Do they eat heart?

Rabbit

We understand that rabbits are harvested year round; however, more are collected in the fall when they are white. Previous information in a dietary survey showed that about a quarter of people from Ndilo and Dettah ate this much rabbit meat 1 day every three weeks or about 17 times a year.

How many eat rabbit meat every day in the fall? How many eat rabbit meat 2 days a week in the fall? How many eat rabbit meat once a week in the fall? How many eat rabbit meat once every 2 weeks? How about in the winter and spring, how often would you eat rabbit (< 1 per week, every few weeks, a couple times per week, every day)? How about in the summer, how often would you eat rabbit (every day, 2 to 4 times a week, 1 per week, every few weeks)? Do you eat this much meat at a meal? or would you eat this much over several meals in a day? How much would you eat if you ate less or more? How about children how much would they generally eat?
Where are you most likely to go to trap rabbits?

Muskrat

Muskrat are generally trapped in March and April. The previous study showed that about a little more than a quarter of people from Ndilo and Dettah ate muskrat. Do you eat muskrat? How many of you ate muskrat in the last year?

One to two people ate this much muskrat meat 1 day every three weeks or about 17 times a year. How many eat muskrat meat once every 3 weeks in the spring? How many eat muskrat meat once every 3 weeks in the spring? How many eat muskrat meat once a week in the spring? Would you eat muskrat in the winter? How about the summer or fall? How many times would you eat?

Do you eat this much meat at a meal? or would you eat this much over several meals in a day? How much would you eat if you ate less or more? How about children do they eat muskrat? How much would they generally eat? Where are you most likely to go to trap muskrat?

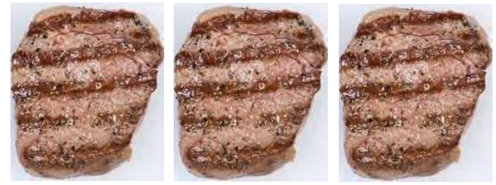
Beaver

Beavers are generally trapped when the ice is thick enough to travel. Most of the trapping seems to be done in March and April (spring). Do you eat beaver? How many of you ate beaver in the last year?

The previous study showed about a quarter of people from Ndilo and Dettah ate beaver 1 day every five weeks or about 10 times a year. How many eat beaver meat once every 5 weeks in the spring? How many eat beaver meat once every 3 weeks? How many eat beaver meat once every 2 weeks? Would you eat beaver in the winter? How about the summer or fall? How many times would you eat?

One person ate this much beaver meat in a day. Do you eat this much meat at a meal/day? How much would you eat if you ate less or more? How about children do they eat beaver? How much would they generally eat? Where are you most likely to go to trap beaver?

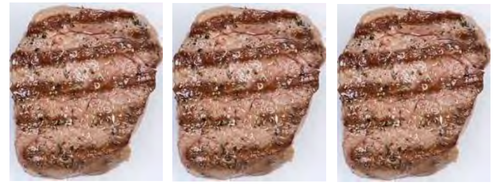
Grouse



Spruce grouse are most likely harvested in the fall and winter but are also caught if seen. Previous information showed that about 1 in 5 people from Ndilo and Dettah ate grouse meat 1 day every 5 weeks or about 10 times a year.

Would you eat grouse every week in the fall/winter? How about once a month? How about in the spring and summer would you eat any grouse? Would you eat more than 10 times a year? About 1 or 2 people ate this much grouse meat in a day. How much do you eat? How many grouse would you have for a family meal? What about children how much would they generally eat? Where are you most likely to go to hunt grouse?

Ptarmigan



Ptarmigan seem to be harvested in the late fall through to the end of winter or early spring. Previous information showed that about 1 in 5 people from Ndilo and Dettah ate ptarmigan meat 1 day every 5 weeks or about 10 times a year.

Would you eat ptarmigan every week in the fall/winter? How about once a month? How about in the spring and summer would you eat any ptarmigan? Would you eat more than 10 times a year?

About 1 or 2 people ate this much ptarmigan meat in a day. How much do you eat? How many ptarmigan would you have for a family meal? What about children how much would they generally eat? Where are you most likely to go to hunt ptarmigan?

Duck

Ducks are reported to be harvested from the spring through to the fall. The previous study showed that about half the people from Ndilo and Dettah ate duck meat 1 day every 3 weeks or about 17 times a year.

In the spring to fall time of harvest would you eat duck? Once a week? Twice a week? Every two weeks? Every three weeks? What about in the winter – how often would you eat duck? Would you eat more than 10 times a year? One person ate this much duck meat in a day. How much would you eat? How many ducks would you have for a family meal? What about children how much would they generally eat? Where are you most likely to go to hunt duck?

Canada Goose

Canada Geese are generally hunted in the spring (late April). The previous study showed that about 1 in 3 people from Ndilo and Dettah ate goose meat 1 day every 5 weeks or about 10 times a year. Did you eat any goose in the last year?

In the spring would you eat goose? Once a week? Once a month? Every three weeks? What about in the winter – would you save a goose for Christmas? What about at other times such as spring or summer, would you eat any goose? Would you eat more than 10 times a year? How much would you eat? Would one goose be good for a family meal? What about children how much would they generally eat? Where are you most likely to go to hunt Canada goose?

Fish serving size

Whitefish

Whitefish are reported to be caught year round. Previous information showed that about 8 in 10 people from Ndilo and Dettah ate whitefish approximately 1 day a week. How many of you eat whitefish? Would you eat more than one day a week?

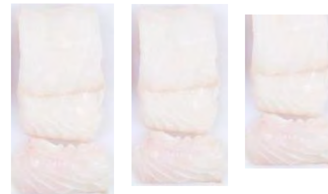
About 25 people said they ate this much whitefish in a day. Would you eat more than this? Would you eat less? How much? How many whitefish would you eat in a week? How about children, how much would they eat? Where would you go to fish for whitefish?

Trout

Trout are reported to be caught year round. Previous information showed that a little less than 8 out of 10 people from Ndilo and Dettah ate trout 1 day every 2 to 3 weeks or 21 times a year. How many of you eat trout? Would you eat more than one day every 2 week? Would you eat once per week?

About 25 people said they ate this much trout in a day. Would you eat more than this? Would you eat less? How much? How many trout would you eat in a week? How about children, how much would they eat? Where would you go to fish for trout?

Connie



From information we have gathered, it seems that connie are rarely caught. Previous information in the dietary survey showed that 1 in 5 people from Ndilo and Dettah ate connie 1 day every 3 weeks or 17 times a year. How many of you ate connie in the last year? Would you eat more than 17 times a year? Less than 17 times a year? 10 times a year? Less than 5 times a year?

About 1 to 2 people people said they ate this much connie in a day. Would you eat more than this? Would you eat less? How much? How about children, how much would they eat? Where would you go to fish for connie?

Pike

Pike have been reported to be caught for dog food. Previous information showed that about 1 in 3 people from Ndilo and Dettah ate pike 1 day every 5 weeks or 10 times a year. How many of you ate pike in the last year? Do you mainly use for dog food?

One person said they ate this much pike in a day. Would you eat more than this? Would you eat less? How much? How about children, would they eat pike? how much would they eat? Where would you go to fish for pike?

 Serving Size equivalent to ½ cup of berries – 50 g berries

Berries

A previous study indicated that more than half the people in the community consume berries about 1 to 2 days per week when they are in season (spring, summer or fall). Would you eat berries every day in season? Once a week?

They generally eat about this much berries in a day. How much would you typically eat in a day (winter (frozen)/spring/summer/fall)? How about children, how much would they eat? Where would you go to gather berries?

Rose Hips

The previous study indicated that about 7 in 100 people from Ndilo and Dettah ate Rose Hips about 1 day every 2 weeks. Rose Hips are harvested in the fall and early winter. How many of you eat Rose Hips? Would you eat rose hips twice a month? Once a month?

How much do you eat? How often? Do you eat the rose hips raw? Do you make tea with them? If you make tea, how do you prepare the tea? How about children, do they eat rose hips? how much would they eat? Where would you go to gather rose hips?

Labrador Tea

The previous study indicated that about 14 in 100 people from Ndilo and Dettah consume Labrador Tea about 1.5 days a week. When do you collect Labrador Tea? How many of you drink Labrador Tea? How often?

How do you prepare the tea? How about children, would they drink Labrador Tea? how much would they drink? Where would you go to gather Labrador tea?

Mushrooms

The previous survey indicated that about 4 in 100 people from Ndilo and Dettah ate mushrooms about 1 day every 5 weeks. How many of you eat mushrooms? Do you only eat in the summer when they are available? Would you eat once a week in the summer? Every couple of weeks?

How much do you eat? How about children, how much would they eat? Where would you go to gather mushrooms?

Chives

The previous study indicated that about 3 in 100 people from Ndilo and Dettah ate chives about 1 day a week. How many of you eat chives? How often would you eat chives? Do you put in food or just eat raw?

How much do you eat? How about children, would they eat chives? Where would you go to gather chives?

Store Bought Foods

In 2014, a study conducted with Dettah indicated that about 94% of the population ate traditional food (meat and fish); 40% said most of their food was traditional food; 40% said about half of their food was traditional food and about 20% said they ate very little traditional food.

How much store bought food do you eat? Do you eat store bought meat 2 to 3 days a week? Do you eat more or less times a week? How about fish, do you eat store bought fish once or twice a week? Do you eat more or less times a week?

APPENDIX F

HUMAN HEALTH EXPOSURE ASSESSMENT

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX F: HUMAN HEALTH EXPOSURE ASSESSMENT

The various assumptions and components that comprised the human health exposure assessment are provided in this appendix, including bioavailability and speciation assumptions, calculated exposure point concentrations (EPCs), exposure equations, and a sample calculation.

F.1 Qualitative Assessment

The initial screen to identify constituents of potential concern (COPC) in soil and water for the Human Health Risk Assessment (HHRA) was described in detail in Appendix D. The screening process for soils identified that antimony, arsenic, cadmium, lead, manganese, vanadium, and zinc were COPC from a consideration of all the soil data at the Giant Mine.

In trying to determine the COPC to carry through for a quantitative evaluation in Ndilo, Dettah, Latham Island, City of Yellowknife, and Ingraham Trail, a qualitative assessment was carried out involving a comparison of the measured concentrations of antimony, arsenic, cadmium, lead, manganese, vanadium, and zinc at each of these locations to the human health component of appropriate guidelines. The human health component of the Canadian Council of Ministers of the Environment (CCME) agricultural soil quality guidelines (CCME 2017) or the human health component of the Ontario Ministry of the Environment and Climate Change (MOECC), formerly the Ontario Ministry of the Environment (MOE 2011) (for antimony and vanadium) were used. The human health components have been derived to be protective of human health. If the soil concentrations were below these human health components, the COPC was not considered further. A check was also made to background concentrations, and if the concentration was below the background, then the COPC was not considered further. The development of background concentrations is discussed in Appendix C.

As this report is a Detailed Quantitative Human Health Risk Assessment, the 95% Upper Confidence Limit of the Mean (95% UCLM) was used in the qualitative assessment to represent a reasonable maximum exposure when there were more than 10 samples. The 95% UCLM was obtained using ProUCL. ProUCL is a statistical program that provides 95% UCLM recommendations (based on data distribution, data set size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate. It is noted that the CCME

(2016) suggest that the BCA bootstrap approach from ProUCL can be used for the majority of datasets.

Table F.1 provides the summary statistics for concentrations of the soils in Ndilo. There are 47 samples for arsenic and 90 samples for each of cadmium, lead, and vanadium. Only 10 samples are available for both antimony and manganese. The table below shows that only antimony and arsenic have 95% UCLM concentrations that exceed the guidelines and background concentrations in Ndilo. For all the other COPC, both the 95% UCLM as well as the 95th percentile values are below guidelines. For manganese, all measured concentrations are below background.

Table F.1 Summary of concentrations of COPC in the soils in Ndilo

COPC	N	N<MDL	Soil Concentration (mg/kg)							
			Min	Max	Average	SD	95th Percentile	95% UCLM	Human Health Component [a]	BG
Antimony	10	0	0.3	79	29	27	70	45	7.5	2.2
Arsenic	47	0	7.0	1060	327	299	917	429	12	94
Cadmium	90	2	0.03	2.8	0.29	0.36	0.60	0.32	1.4	-
Lead	90	0	1.3	158	11	18	26	19	140	20
Manganese	10	0	6.0	31	19	9.0	30	25	-	165
Vanadium	90	1	1.0	105	31	16	49	34	39	68

Note: N – Number of samples; MDL – Method Detection Limit; UCLM – Upper Confidence Limit of Mean; BG – background; '-' – No value available.
[a] Human health component of the Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline component if CCME value unavailable. The component values for antimony and vanadium are from the MOE (2011); these values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.
COPC in **bold** are carried forward to a quantitative assessment.

Table F.2 provides the summary statistics for concentrations of the soils in Latham Island. There are very few soil samples collected on Latham Island itself; however, there are many other samples collected for Ndilo, which should have similar concentrations and soil characteristics; therefore, the two data sets were combined. There are 53 samples for arsenic and over 90 samples for cadmium, lead, and vanadium. Only 12 samples are available for antimony and manganese. Similar to Ndilo, only antimony and arsenic have 95% UCLM concentrations that exceed the guidelines and background.

Table F.2 Summary of concentrations of COPC in the soils in Latham Island

COPC	N	N<MDL	Soil Concentration (mg/kg)							
			Min	Max	Average	SD	95th Percentile	95% UCLM	Human Health Component [a]	BG
Antimony	12	0	0.30	79	25	27	67	39	7.5	2.2
Arsenic	53	0	5.9	1060	293	297	906	385	12	94
Cadmium	90	2	0.03	2.8	0.29	0.36	0.59	0.32	1.4	-
Lead	90	0	1.3	158	11	18	26	19	140	20
Manganese	12	0	6.1	49	21	13	39	27	-	165
Vanadium	90	1	1.0	105	31	16	49	34	39	68

Note: N – Number of samples; MDL – Method Detection Limit; UCLM – Upper Confidence Limit of Mean; BG – background; '-' – No value available. COPC in **bold** are carried forward to a quantitative assessment.
[a] Human health component of the Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline component if CCME value unavailable. The component values for antimony and vanadium are from the MOE (2011); these values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.

Table F.3 provides the summary statistics for concentrations of the soils in the City of Yellowknife. There are 260 samples for arsenic and 34 samples for each of antimony and manganese. Only nine samples are available for cadmium, lead, and vanadium, which were obtained from a mushroom sampling program by Obst (2014). The table shows that, in the City of Yellowknife the 95% UCLM concentration of arsenic exceeds the guideline and background. The 95% UCLM for manganese exceeds the background concentration as well. For lead and vanadium, there are only 9 samples and the maximum concentrations are below guidelines or background. The maximum concentration of cadmium at 2 mg/kg is just above the guideline of 1.4 mg/kg; however, all other concentrations are measured at 0.1 or 0.2 mg/kg, thus, cadmium is not considered further.

Table F.3 Summary of concentrations of COPC in the soils in City of Yellowknife

COPC	N	N<MDL	Soil Concentration (mg/kg)							
			Min	Max	Average	SD	95th Percentile	95% UCLM	Human Health Component [a]	BG
Antimony	34	2	0.1	17	2.1	3.3	7.3	3.7	7.5	2.2
Arsenic	260	0	3.6	1190	90	135	301	110	12	94
Cadmium	9	1	0.05	2	0.5	0.6	1.4	NA	1.4	-
Lead	9	0	4	126	39	41	112	NA	140	20
Manganese	34	0	1.6	1890	236	425	1026	364	-	165
Vanadium	9	0	10	60	25	14	47	NA	39	68

Note: N – Number of samples; MDL – Method Detection Limit; UCLM – Upper Confidence Limit of Mean; BG – background; '-' – No value available. COPC in **bold** are carried forward to a quantitative assessment.
[a] Human health component of the Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline component if CCME value unavailable. The component values for antimony and vanadium are from the MOE (2011); these values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.

Table F.4 provides the summary statistics for concentrations of the soils along the Ingraham Trail. There are very few samples available. Based on this small dataset, the 95% UCLM concentration of antimony exceeds the guideline. The dataset for manganese was skewed, and, thus, the 95th percentile was used for comparison. The 95th percentile manganese concentration is above background. For arsenic, the 95% UCLM concentration is below background and for all other COPC, the maximum concentrations are below guidelines or background. Additional samples of soils along the Ingraham Trail were collected by students from Queen's University in 2017 and provided in a report from the Northwest Territories Geological Survey (Jamieson et al. 2017). Appendix P provides the information. The consideration of the 16 additional samples along the Ingraham Trail results in lower concentrations and thus the qualitative assessment provided here is unchanged.

Table F.4 Summary of concentrations of COPC in the soils in Ingraham Trail

COPC	N	N<MDL	Soil Concentration (mg/kg)							
			Min	Max	Average	SD	95th Percentile	95% UCLM	Human Health Component [a]	BG
Antimony	12	0	0.4	69	8.6	20	38	65	7.5	2.2
Arsenic	12	0	7.1	127	32	34	96	57	12	94
Cadmium	2	0	0.2	0.5	0.35	0.21	0.49	NA	1.4	-
Lead	2	0	22	122	72	71	117	NA	140	20
Manganese	12	0	15	500	79	135	285	NA	-	165
Vanadium	2	0	10	20	15	7	20	NA	39	68

Note: N – Number of samples; MDL – Method Detection Limit; UCLM – Upper Confidence Limit of Mean; BG – background; '-' – No value available.
[a] Human health component of the Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline component if CCME value unavailable. The component values for antimony and vanadium are from the MOE (2011) - these values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.
COPC in **bold** are carried forward to a quantitative assessment.

Table F.5 provides the summary statistics for concentrations of the soils in Dettah. Chemistry data are only available for arsenic, antimony, and manganese and again there is only a small dataset. The maximum concentration of arsenic is above guidelines and background. The maximum concentrations of antimony and manganese are below guidelines or background. Additional samples of soils in Dettah were collected by students from Queen's University in 2017 (Jamieson et al. 2017). Appendix P provides the information. The consideration of the two additional samples in Dettah results in lower concentrations and thus the qualitative assessment provided here is unchanged.

Table F.5 Summary of concentrations of COPC in the soils in Dettah

COPC	N	N<MDL	Soil Concentration (mg/kg)						
			Min	Max	Average	SD	95th Percentile	Human Health Component [a]	BG
Antimony	8	0	0.17	6.2	2.4	2.4	6.0	7.5	2.2
Arsenic	9	0	7.2	144	44	50	133	12	94
Manganese	8	0	5.8	59	28	17	53	-	165

Note: N – Number of samples; MDL – Method Detection Limit; UCLM – Upper Confidence Limit of Mean; BG – background; '-' – No value available.
[a] Human health component of the Canadian Council of Ministers of the Environment (CCME 2017) agricultural land use guideline supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline component if CCME value unavailable. The component values for antimony and vanadium are from the MOE (2011) - these values are based on an agricultural scenario similar to the CCME and are deemed appropriate for use.
COPC in **bold** are carried forward to a quantitative assessment.

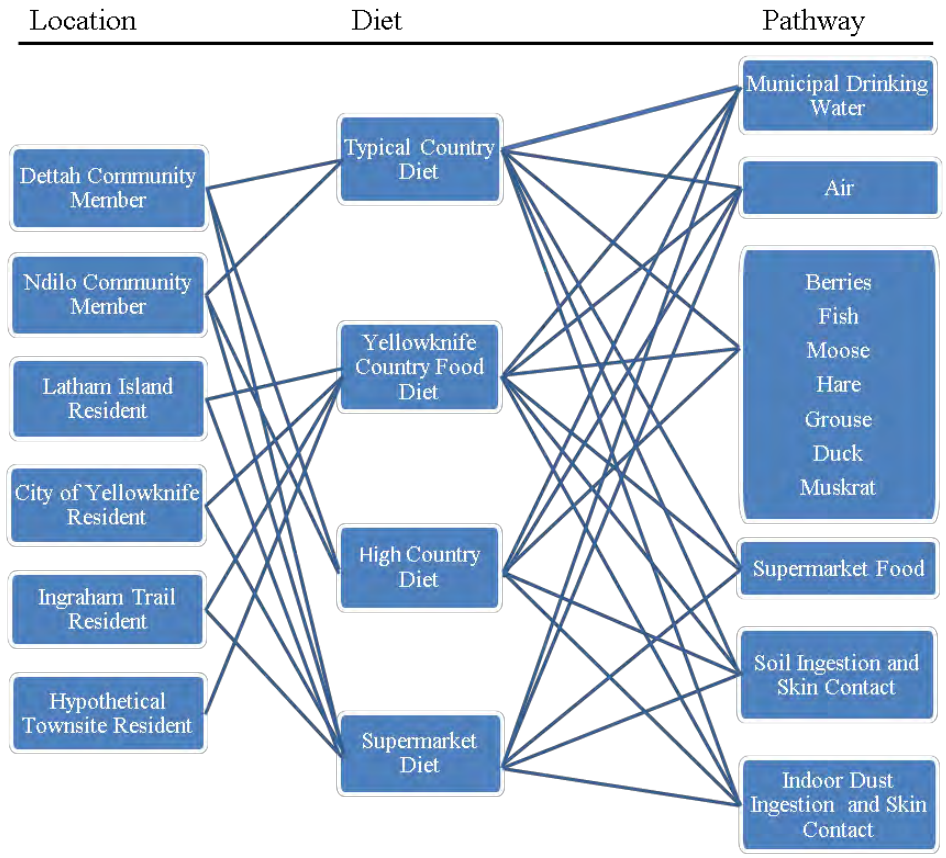
Based on the qualitative analysis on the soils, concentrations of cadmium, lead, and vanadium are below guidelines and/or background and, thus, do not represent a risk from an HHRA perspective. Arsenic, antimony, and manganese are the only COPC carried forward for a quantitative analysis.

F.2 Exposure Scenarios

F.2.1 Current

The exposure assessment estimated exposures to people living in the vicinity of the Giant Mine with diets characterized in Appendix E at specific locations of interest. The exposure scenario that is considered to represent exposures at every location (i.e., base case) is provided in Figure F.1. It was assumed in this scenario that the source of drinking water for all residents was the municipal source and that all people would be exposed to concentrations in the air, soil, and indoor dust where they live. Thus, this scenario captures the unique exposure in their areas. Members of the Yellowknives Dene First Nation (YKDFN) community (Ndilo and Dettah) were assumed to have either a purely supermarket food diet, a typical country food diet that is also supplemented with supermarket food, or a high country food diet. People in the City of Yellowknife were assumed to have a purely supermarket food diet. In addition, because the Metis community also lives there and has some avid hunters and fishers, it was assumed that these people would eat some country food as well as supermarket food. It was assumed that the Ingraham Trail resident would also have a similar country food diet as the City of Yellowknife country food eaters. An unrealistic scenario was also evaluated where it was assumed that someone with a typical country food diet was living at the former Townsite. This scenario is used to demonstrate the impact of the remedial actions on the former Townsite location.

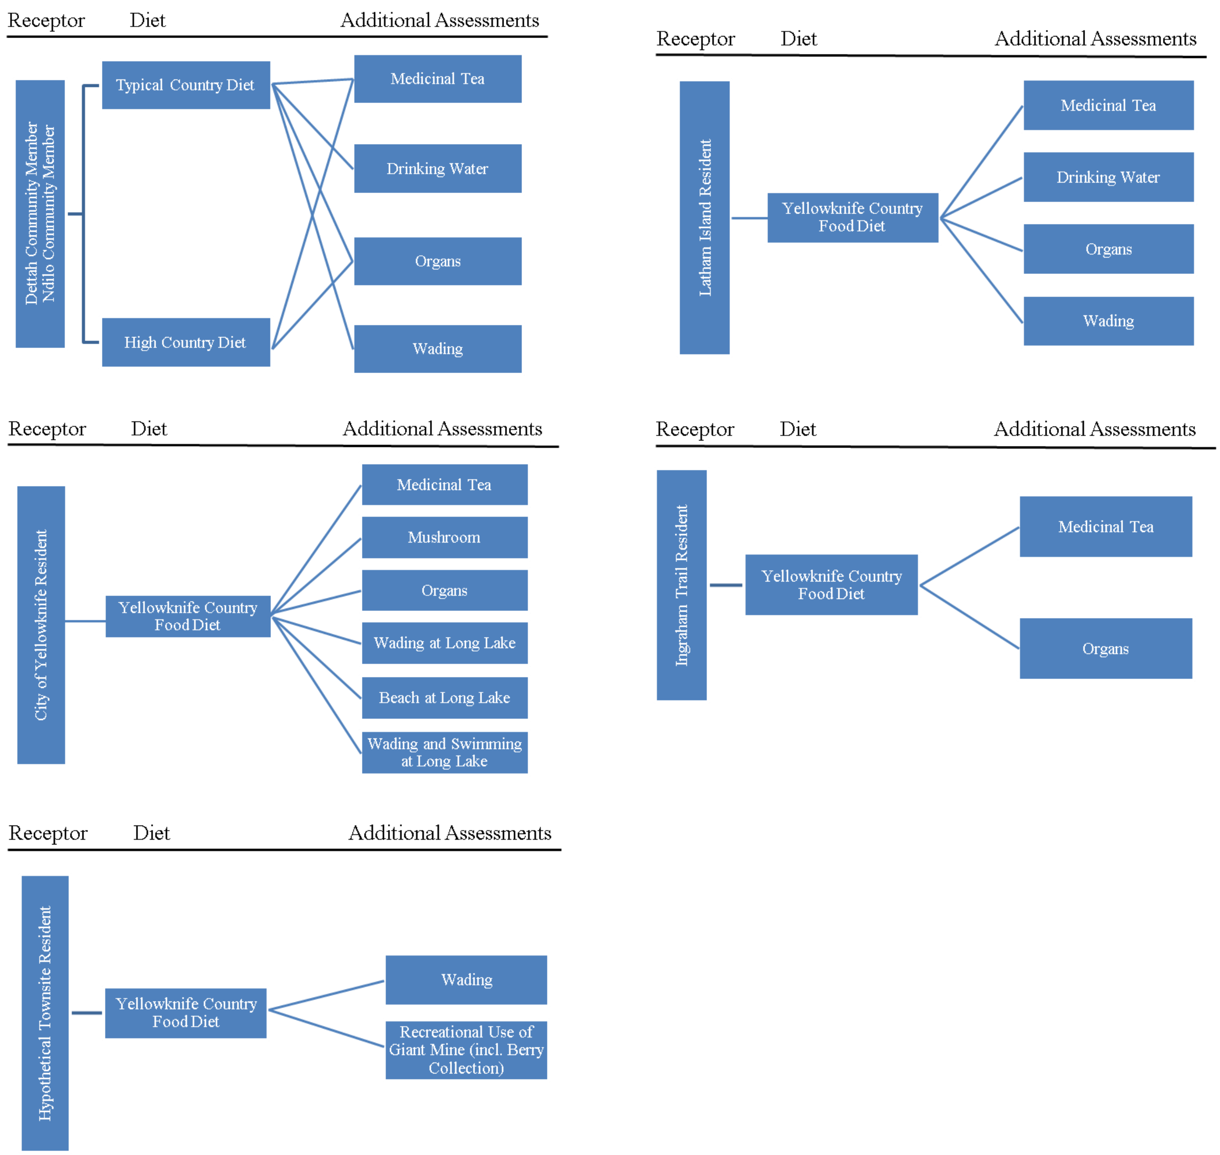
Figure F.1 Base case exposure scenario



Other scenarios were also considered that were added to the base case. These scenarios are summarized in Figure F.2. The scenarios for Ndilo and Dettah involve the assumption that people in these two communities would drink water from Yellowknife Bay instead of from the municipal source and that they would also wade in the shallow shoreline sediments. In addition, it was assumed that organs from moose, fish, and birds would be eaten and that they would drink medicinal tea. The exposures for the different scenarios were added to the base case scenario. These same scenarios were considered for the Latham Island resident.

The Metis indicated in the dietary survey that they consumed mushrooms and, therefore, this scenario was considered for the City of Yellowknife resident that has a country food diet. In addition, the Fred Henne Campground and Long Lake were identified as areas where residents like to go and camp and swim/wade; thus, this scenario was considered. Eating organ meat and drinking medicinal tea was also evaluated for the City of Yellowknife resident, as well as the Ingraham Trail resident. For the unrealistic scenario at the former Townsite, it was assumed that people would wade in the shallow sediments. This wading scenario is also used to evaluate exposures at the boat launch and marina areas as the sediment concentrations are similar. An unrealistic scenario where people could access the Giant Mine under current conditions was also used to help frame the impact of the remedial activities.

Figure F.2 Additional exposure scenarios considered



F.2.2 Future

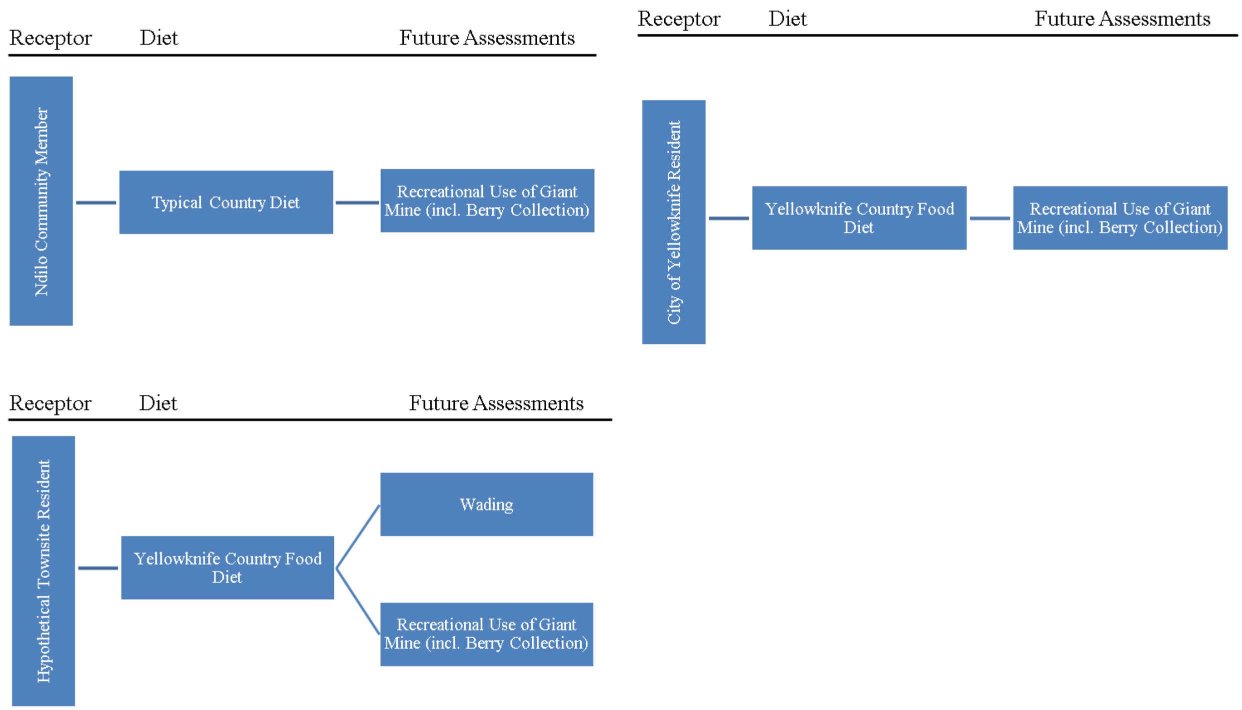
The objective of the HHRA is to determine the effects of the remedial activities at the Giant Mine on the residents in the vicinity of the site. The remedial actions at the site involve the capping of the tailings, the remediation of arsenic concentrations in the disturbed areas of the site to the GNWT industrial criterion, active management in the form of excavation and/or fencing of areas with arsenic concentrations above

3000 mg/kg, and moving the water treatment discharge pipe to near the mouth of Baker Creek. These remedial activities will not have any effect on the unique location exposures that were evaluated in the base case. In addition, remedial activities will not impact on the concentrations in the country foods, as none of the samples were obtained from the Giant Mine. The remedial activities will allow access to the Giant Mine for recreational activities such as walking, running, cycling etc., and this exposure was evaluated in the future scenario. The effect of relocating the treated water discharge to near the mouth of Baker Creek was evaluated using modelling (see Appendix K) to determine the future water and sediment concentrations in Back Bay and North Yellowknife Bay. The modelling determined that the concentrations in the future are expected to be no different than the current measured concentrations.

Figure F.3 provides a summary of the exposure scenarios considered for future conditions. As seen in the future scenario, it was assumed that people in Ndilo would spend some time at the Giant Mine doing recreational activities. It was also assumed that, while they were on the site, they may pick some berries if they were in season (assumed to be 5% of total berry consumption). An evaluation of a City of Yellowknife resident spending time at the Giant Mine for recreational activities was also evaluated, including 5% of berry consumption from the site.

At the former Townsite, the remedial actions involve clean-up of the soils to the arsenic GNWT residential criterion. No plans have been made for the final land use in this area; however, the risk assessment has evaluated the strictest land use where someone would live in this area. Additional details on exposure assumptions and scenario selection are provided in Appendix E.

Figure F.3 Exposure scenarios for future conditions



F.3 Bioavailability/Bioaccessibility

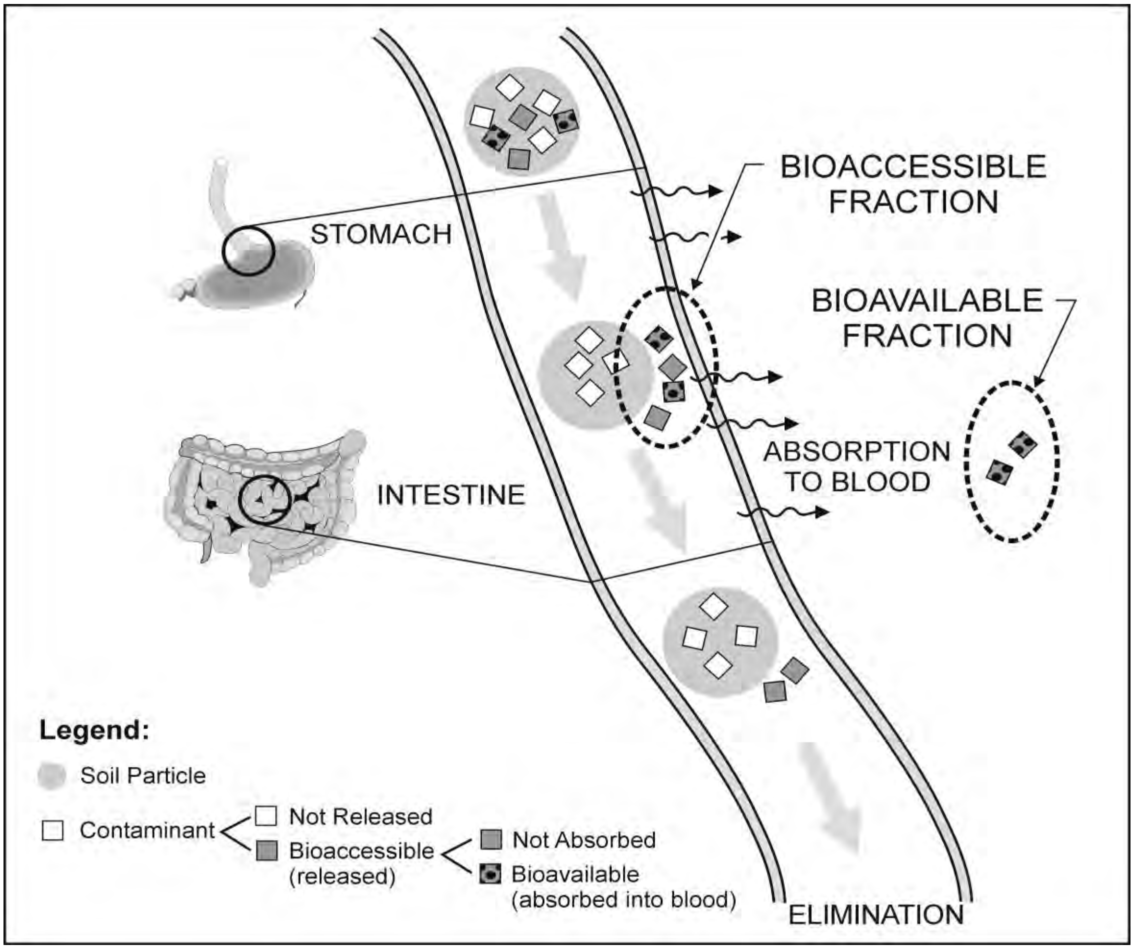
Oral bioavailability is defined as the fraction of an administered dose that reaches the central blood compartment from the gastrointestinal tract. Bioavailability defined in this manner is commonly referred to as "absolute bioavailability".

Relative bioavailability refers to comparative bioavailabilities of different forms of a substance or for different exposure media containing the substance (i.e., bioavailability of a metal from soil relative to its bioavailability from water). This is generally referred to as a Relative Absorption Factor (RAF). This is discussed in Section F.6 for dermal absorption.

The oral bioaccessibility of a substance is the fraction of the administered dose that is soluble in a gastrointestinal environment and is available for absorption (into the central blood compartment). The bioaccessible fraction is not necessarily equal to the RAF but depends on the relation between results from a particular *in vitro* test system and an appropriate *in vivo* model. Oral bioaccessibility is the measure of arsenic availability that is considered for the risk assessment.

Figure F.4 provides a schematic representation of the difference between bioaccessibility and bioavailability.

Figure F.4 Schematic representation of bioaccessibility and bioavailability



For the Giant HHRA, it was important to examine the bioaccessibility of arsenic in particular since it was the primary chemical associated with the activities at the Giant Mine and it is present in many different chemical forms (e.g., arsenopyrite, arsenic trioxide, etc.). Some of these forms can be absorbed into the bloodstream while others cannot. In this study, laboratory analyses of soils, sediments, fish tissue, and plants were conducted to determine the levels of arsenic that were available for exposure.

For the purposes of the Giant Mine, data on arsenic bioaccessibility in soils, sediments, and fish were obtained from samples collected in the study area as part of sampling programs for the Giant Mine Remediation Program (GMRP). Bioaccessibility data for arsenic in plants and wildlife were obtained from a publication by Koch et al. (2013)

related to bioaccessibility and speciation of arsenic in country foods from contaminated sites in Canada where Giant Mine was part of the study.

The bioaccessibility of antimony and manganese were assumed to be 100% for this study, as there were no available data. This represents a conservative assumption.

F.3.1 Bioaccessibility in Soils

As part of the GMRP, soil samples were collected across the Giant Mine, and a subset of the samples were sent for analysis of arsenic bioaccessibility at Royal Military College (RMC). Samples were obtained from both disturbed and undisturbed areas at the Giant Mine. These samples were reviewed and considered in determination of the bioaccessibility or arsenic in soils at the Giant Mine.

In addition, soils were collected at the former Giant Mine Townsite area and off site at Long Lake where people camp and a subset of the samples were sent for bioaccessibility analyses.

F.3.1.1 Undisturbed Soils on Giant Mine

The data for bioaccessibility for the undisturbed soils was obtained from a Golder (2016a) report entitled *Arsenic Characterization Undisturbed Areas Giant Mine, Yellowknife NT.* According to this report, 10 shallow soil samples were collected in the undisturbed areas of the Giant Mine, and all were submitted to Dr. Iris Koch at the RMC to conduct arsenic bioaccessibility testing using the Environmental Sciences Group (ESG) glycine method. The glycine method simulates the leaching of material from the soils into the gastrointestinal tract and is considered to measure the fraction of arsenic that is available for absorption. Figure F.5 provides a map of the Giant Mine indicating the locations of the samples that were sent for bioaccessibility testing, and Table F.6 provides a summary of the bioaccessibility results for the undisturbed soils. Undisturbed soils are defined as soils where no mining or milling activities occurred. These areas are characterized by bedrock outcrops, wetlands, and forested areas.

As seen from the table, even though the total arsenic in the undisturbed soils ranged from 135 mg/kg to 3,700 mg/kg, there is no corresponding increase in the % bioaccessibility of arsenic. In fact, the lowest arsenic concentration in soils reports a bioaccessibility over 100%. Golder (2016a) reports that they believed that the total arsenic measured in this sample (IV-F-2) that came from a forested area may have been low due to the heterogeneity and organic content issues associated with the sample and that this sample was not considered to be reliable. For the purposes of the risk assessment, an average concentration was used to apply to the undisturbed soils. Based on nine samples (minus IV-F-2), the average arsenic bioaccessibility was 38% for the undisturbed soils. This value was considered to be a reasonable representation of the bioaccessibility of arsenic in the undisturbed soils at the Giant Mine as seven of the nine samples have bioaccessibility values in the 22% to 43% range (mean 31%).

Figure F.5 Map showing locations of bioaccessibility samples in undisturbed soils

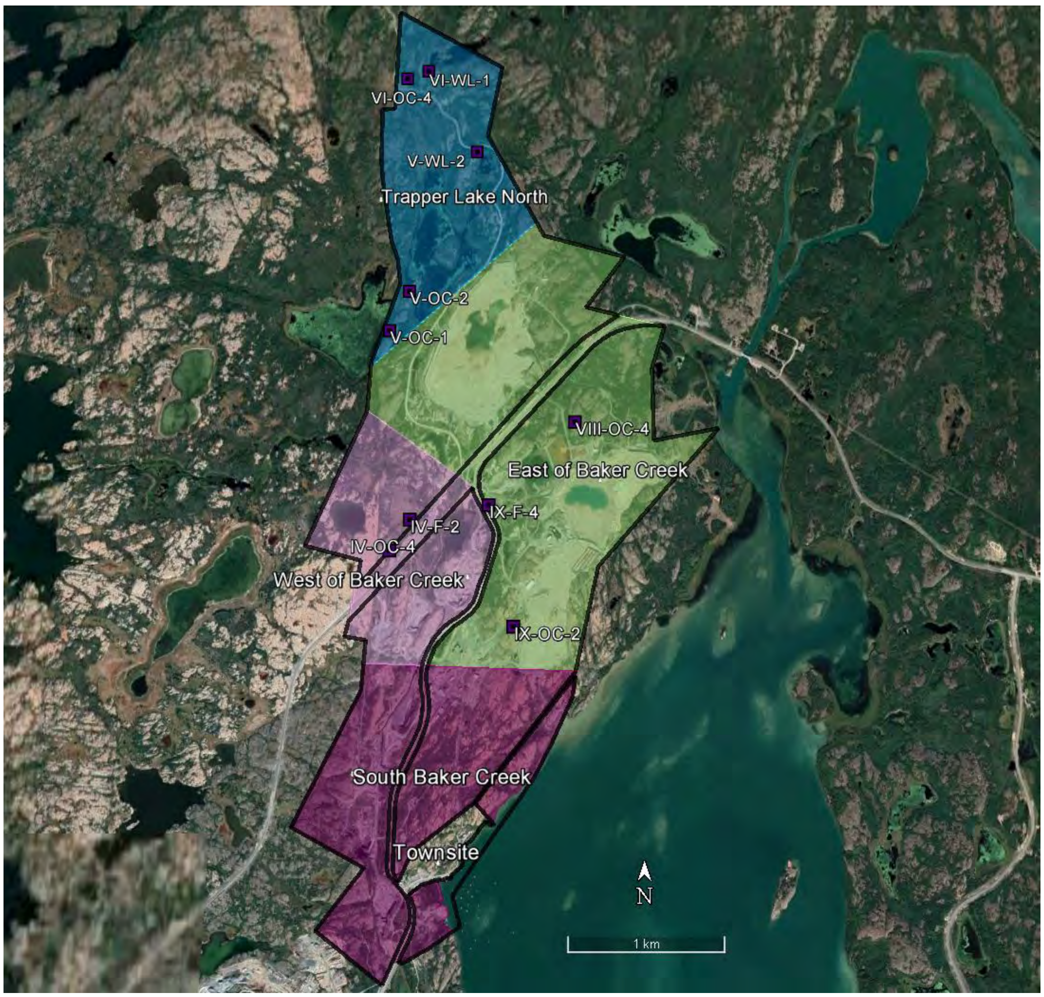


Table F.6 Summary of arsenic bioaccessibility results for undisturbed soils

Sample ID	Medium	Depth (mbgs)	Arsenic (mg/kg)	Bioaccessibility	
				BA As (mg/kg)	Ba As (%)
IV-OC-4	Soil	0-0.1	3700	803	22
IX-OC-2	Soil	0-0.1	660	287	43
VIII-OC-4	Soil	0-0.1	790	223	28
VI-OC-4	Soil	0-0.1	510	123	24
V-OC-1	Soil	0-0.1	960	208	22
V-OC-2	Soil	0-0.1	205	133	65
IV-F-2	Soil	0-0.1	135	229	170
IX-F-4	Soil	0-0.1	200	85	43
V-WL-2	Soil	0-0.1	240	150	63
VI-WL-1	Soil	0-0.1	770	267	35

Note: Sample IV-F-2 is not considered reliable. The average bioaccessibility of the other nine samples is 38%.

F.3.1.2 Disturbed Soils on Giant Mine

The data for bioaccessibility for the disturbed soils was obtained from a Golder (2016a) report entitled *Arsenic Characterization Disturbed Areas Giant Mine, Yellowknife NT*. A total of 82 samples were collected in disturbed areas of the Giant Mine. These were tailings areas and the Mill area. A subset of these samples (38 samples were sent for bioaccessibility analysis at RMC). Figure F.6 provides a map of the Giant Mine indicating the locations of the samples of disturbed soils that were sent for bioaccessibility testing, and Table F.7 provides a summary of the bioaccessibility results for the disturbed soils. Concentrations of arsenic in the tailings areas ranged from 665 mg/kg to 2,848 mg/kg and the % bioaccessibility ranged from 21% to 90%. Average bioaccessibilities in the tailings basins were as follows:

- south tailings basin – 50%;
- central tailings basin – 43%;
- north tailings basin – 36%; and
- northwest tailings basin – 48%.

The average overall bioaccessibility in the four tailings basins was 44%. For the Mill Area, arsenic concentrations ranged from 590 mg/kg to 5300 mg/kg, with an average bioaccessibility of 16%. The average arsenic bioaccessibility of the disturbed soils is 36% and was used to represent future conditions on the Giant Mine. The ERA considered the bioaccessibility for the different areas.

Figure F.6 Map showing locations of bioaccessibility samples in disturbed soils

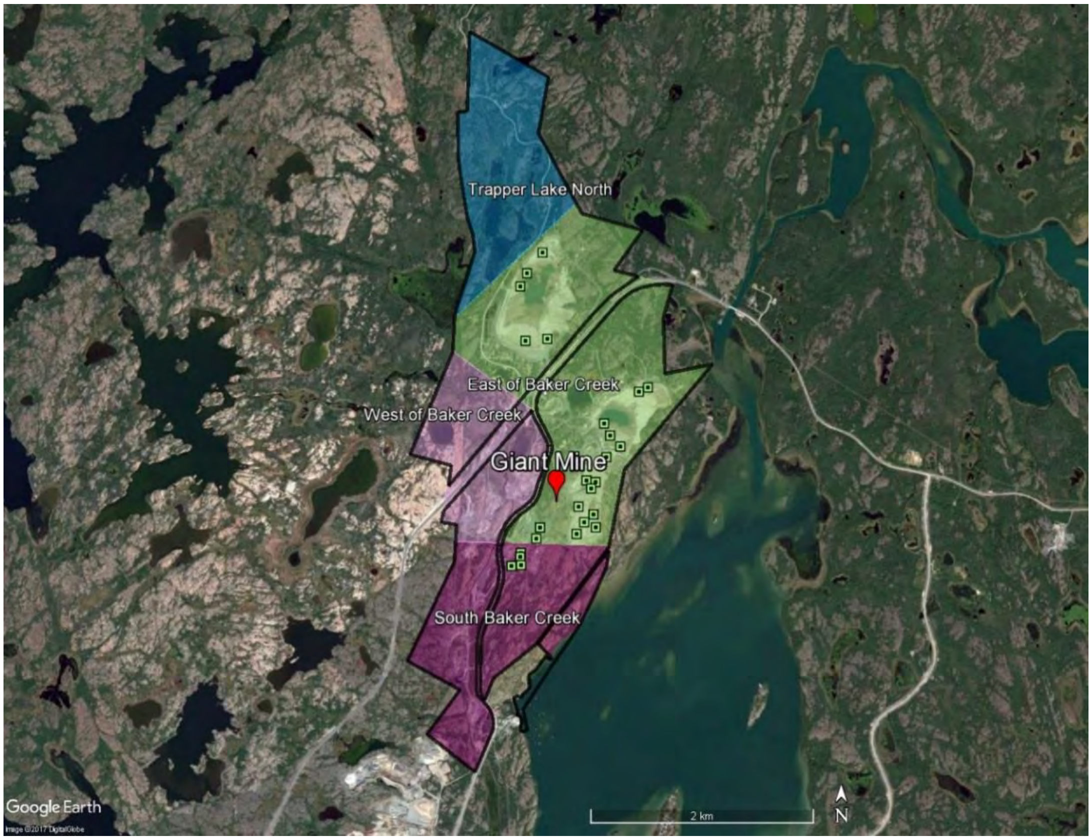

Table F.7 Summary of arsenic bioaccessibility results for disturbed soils

Sample Location	Sample ID	Depth (m bgs)	Total Arsenic (mg/kg)	Bioaccessibility	
				BA As (mg/kg)	BA As (%)
South Tailings Basin	ST-SS-01-1	0.0 - 0.10	3,150	1,207	38

	TP15-06-3	0.50 - 1.0	590	341	58

Note: The average bioaccessibility of the undisturbed soils is 36%.

F.3.1.3 Former Townsite

As part of the data gaps analysis for the risk assessment, it was determined that additional soil data as well as bioaccessibility information was needed for soils in the former Townsite area. Golder collected this additional information in the summer of 2016 and provided the results in a technical memo entitled *Giant Mine Data Report- Human Health and Ecological Risk Assessment Data Gaps* (Golder 2016b). Ten soil samples were collected and eight samples were sent to RMC for bioaccessibility analysis. Figure F.7 provides a map of the former Townsite indicating the locations of the samples that were sent for bioaccessibility testing, and Table F.8 provides a summary of the bioaccessibility results for the former Townsite soils. As seen from the table, the arsenic concentrations in the soil ranged from 280 mg/kg to 4,300 mg/kg and the bioaccessibility ranged from 7% to 54%. The average bioaccessibility of the 8 samples is 30%. This is similar to the bioaccessibility for the disturbed soils on the Giant Mine.

Figure F.7 Map showing locations of bioaccessibility samples for former Townsite soils

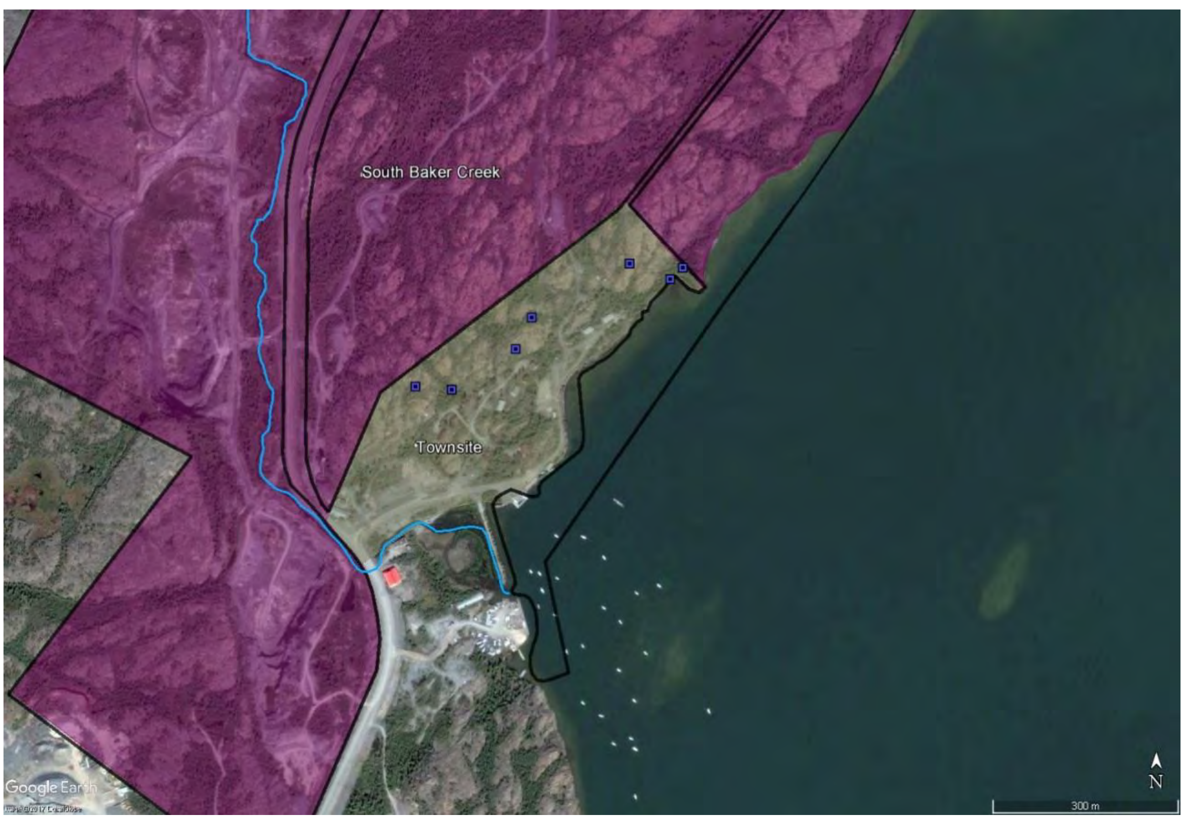

Table F.8 Summary of arsenic bioaccessibility results for former Townsite soils

Sample ID	BA Conc. (mg/kg dw)	Soil Conc. (mg/kg dw)	% As BA
SL-F-01-1 B2	100	1400	7.1
TS-F-02-1 B2	156	290	54
SL-F-03-1	63	280	22
SL-F-08-1	124	300	41
TS-OC-02-1 B2	310	1100	28
TS-OC-01-1 B2	561	2000	28
TS-OC-04-1 B2	274	1800	15
SL-OC-04-1	1803	4300	42

Note: The average bioaccessibility of the former Townsite soils is 30%.

F.3.1.4 Fred Henne Campground

As part of the data gaps analysis for the risk assessment, it was determined that additional soil data as well as bioaccessibility information was needed for soils at the Fred Henne Campground on Long Lake. This area is near the airport and is used by people in the Yellowknife area. Golder collected this additional information in the summer of 2016 and provided the results in a technical memo entitled *Giant Mine Data Report – Human Health and Ecological Risk Assessment Data Gaps* (Golder 2016b). Ten soil samples were collected at ten campsites focussing on areas where people would set up tents. Five samples were sent to RMC for bioaccessibility analysis.

Figure F.8 provides a map of indicating the locations of the soil samples in the Fred Henne Campground that were sent for bioaccessibility testing and Table F.9 provides a summary of the bioaccessibility results for the soils at the Fred Henne Campground. As seen from the table, the arsenic concentrations in the soil ranged from 50 mg/kg to 210 mg/kg, and the bioaccessibility was fairly consistent and ranged from 30% to 42%. The average bioaccessibility of the five samples is 36%. This is similar to the bioaccessibility for the undisturbed soils on the Giant Mine.

Figure F.8 Map showing locations of bioaccessibility samples for Fred Henne Campground soils

Table F.9 Summary of arsenic bioaccessibility results for Fred Henne Campground soils

Sample ID	BA Conc. (mg/kg dw)	Soil Conc. (mg/kg dw)	% As BA
16-Long Lake S-2	50	160	31
16-Long Lake S-3	49	160	30
16-Long Lake S-7	29	73	39
16-Long Lake S-8	89	210	42
16-Long Lake S-10	19	50	38

Note: The average bioaccessibility of the soils at the Fred Henne Campground is 36%.

F.3.2 Bioaccessibility in Sediments

F.3.2.1 Baker Creek

The Golder (2015) report entitled *Assessment of Arsenic in Sediment/Surface Water in Upper Baker Creek - Giant Mine Lease and Adjacent Lands* provides information on sediment samples collected in the upper reaches of Baker Creek. Ten sediment samples from Reaches 6 and 7 to 11 in Baker Creek were sent to RMC for bioaccessibility analysis.

Figure F.9 provides a map of Baker Creek indicating the locations of the samples that were sent for bioaccessibility testing, and Table F.10 provides a summary of the bioaccessibility results for the sediments in the upper reaches of Baker Creek. As seen from the table, the arsenic concentrations in the sediments ranged from 140 mg/kg to 1,500 mg/kg, and the bioaccessibility ranged from 9% to 44%. The average bioaccessibility in Reach 7 to 11 (all samples with the exception of BC-R6-001 [in Reach 6]) is 17%. For Reach 6, the single bioaccessibility in the sample of 44% was used in the risk assessment. This is the highest recorded bioaccessibility value in Baker Creek, therefore it may represent a conservative value for Reach 6.

Figure F.9 Map showing locations of bioaccessibility samples for sediments in Baker Creek

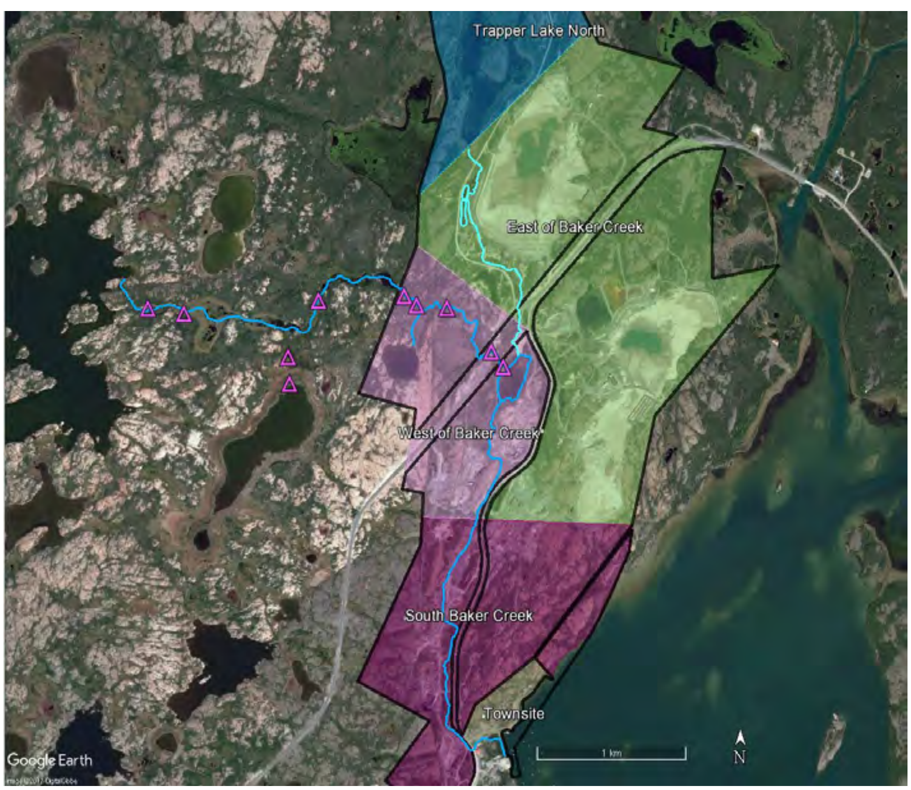

Table F.10 Summary of arsenic bioaccessibility results for sediments in Baker Creek

Sample ID	Arsenic Concentration (mg/kg dw)			% Arsenic Bioaccessibility
	Original Sediment	Dewatered Sediment	Bioaccessible (dewatered)	
BC-R6-001	340	380	166	44
BC-R07-002	180	180	58	32
BC-R09-015	320	310	37	12
BC-R09-018	220	250	30	12
BC-R09-020	140	140	21	15
BC-R10-028	550	560	81	14
BC-R10-039	350	410	53	13
BC-R11-029	220	260	47	18
UL1-042	460	510	113	22
UL1-043	1500	1400	123	9

Note: The average bioaccessibility of the sediments in Reaches 7 to 11 in Baker Creek is 17%.

F.3.2.2 Former Townsite

As part of the data gaps analysis for the risk assessment, it was determined that additional sediment data as well as bioaccessibility information was needed for sediments along the shoreline in the former Townsite area. This information is important to evaluate the potential for people wading in the shallow water in that area currently and in the future. Golder collected this additional information in the summer of 2016 and provided the results in a technical memo entitled *Giant Mine Data Report - Human Health and Ecological Risk Assessment Data Gaps* (Golder 2016b). Ten sediment samples were collected along the shoreline, and ten samples were sent to RMC for bioaccessibility analysis. Figure F.10 provides a map of the shoreline along the former Townsite indicating the locations of the samples that were sent for bioaccessibility testing, and Table F.11 provides a summary of the bioaccessibility results for the former sediments along the shoreline of the former Townsite. As seen from the table, the arsenic concentrations in the sediments ranged from 64 mg/kg to 1400 mg/kg and the bioaccessibility ranged from 16% to 35%. The average bioaccessibility of the 10 sediment samples is 26%. This is similar (slightly lower) to the bioaccessibility for the soils in this area, which is around 30%.

Figure F.10 Map showing locations of bioaccessibility samples for sediments along the shoreline of the former Townsite

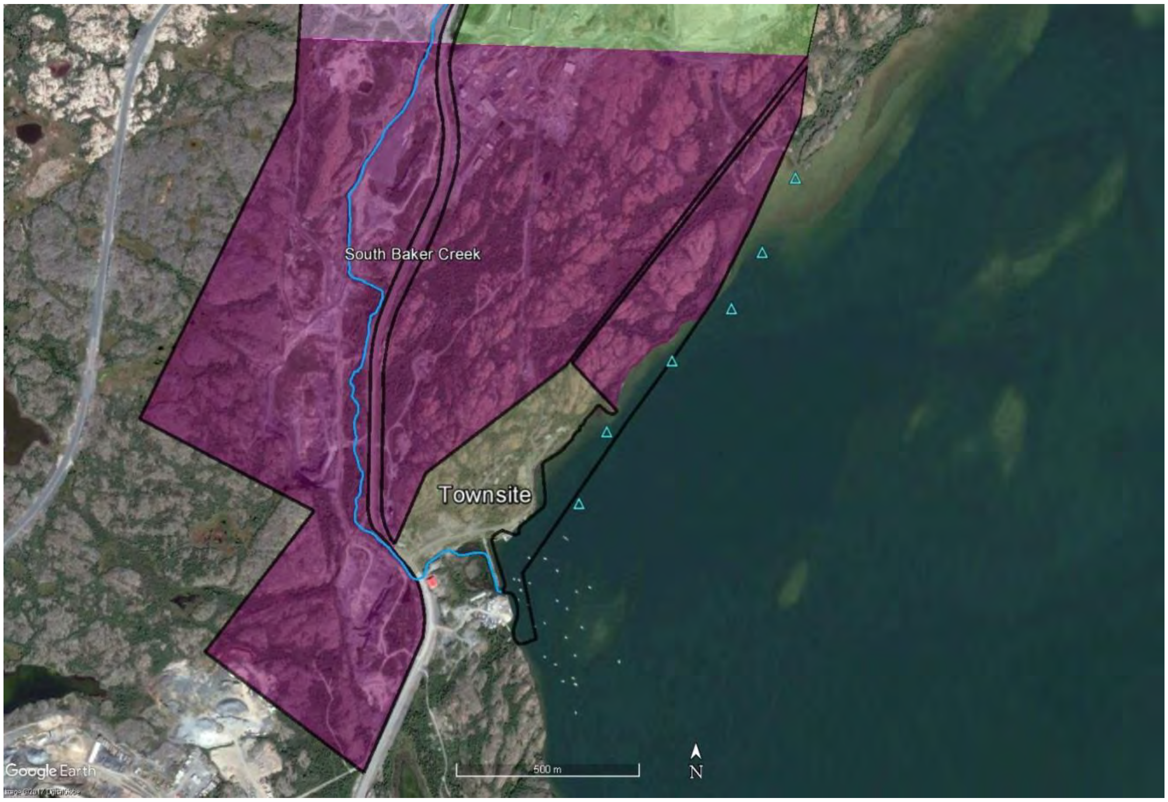

Table F.11 Summary of arsenic bioaccessibility results for sediments along the shoreline of the former Townsite

Sample ID	Depth (cm)	BA Conc. (mg/kg dw)	Sediment Conc. (mg/kg dw)	% As BA
2016 SQ-A-1	0 - 5	150	825	18
2016 SQ-A-2	5-10	130	840	16
2016 SQ-B-1	0 - 5	130	370	35
2016 SQ-B-2	5-10	157	670	23
2016 SQ-C-1	0 - 5	17	62	28
2016 SQ-O-50-1	5-10	269	1200	22

2016 SQ-1S-100-1	0-10	108	350	31
2016 SQ-2S-100-1	0 - 5	214	630	34
2016 SQ-2S-100-3	>10	88	320	28

Note: The average bioaccessibility of the sediments along the shoreline at the former Townsite is 26%.

F.3.2.3 Long Lake

As part of the data gaps analysis for the risk assessment, it was determined that additional sediment data as well as bioaccessibility information was needed for shallow sediments along the shoreline of Long Lake. This information is very helpful, as people swim and use the beach area at Long Lake. Golder collected this additional information in the summer of 2016 and provided the results in a technical memo entitled *Giant Mine Data Report - Human Health and Ecological Risk Assessment Data Gaps* (Golder 2016b). Ten sediment samples were collected along the public beach, day use, and boat launch areas. Five samples were sent to RMC for bioaccessibility analysis. Figure F.11 provides a map indicating the locations of the sediment samples in Long Lake that were sent for bioaccessibility testing, and Table F.12 provides a summary of the bioaccessibility results for the sediments in Long Lake. As seen from the table, the arsenic concentrations in the sediments ranged from 9 mg/kg to 100 mg/kg and the bioaccessibility ranged from 30% to 55%. The average bioaccessibility of the 5 samples is 45%.

Figure F.11 Map showing locations of bioaccessibility samples for shallow sediments in Long Lake

Table F.12 Summary of arsenic bioaccessibility results for shallow sediments in Long Lake

Sample ID	BA Conc. (mg/kg dw)	Sediment Conc. (mg/kg dw)	% As BA
16-Long Lake S-2	3.4	9	38
16-Long Lake S-3	6	20	30
16-Long Lake S-7	49	100	49
16-Long Lake S-8	23	42	55
16-Long Lake S-10	9.4	18	52

Note: The average bioaccessibility of the shallow sediments in Long Lake is 45%.

F.3.3 Bioaccessibility in Fish

Stantec (2014), in a report entitled *Analysis of Contaminants in Tissues of Fish Captured in the Yellowknife Bay Area, NT*, provides bioaccessibility data on large-bodied fish such as northern pike, lake whitefish, and inconnu caught at the mouth of Baker Creek and various areas in Yellowknife Bay, including a background area (Horseshoe Island for lake whitefish and northern pike, and Mackenzie Island for inconnu). Fish samples were sent to RMC for bioaccessibility testing. The results of the bioaccessibility testing for lake whitefish, northern pike, and inconnu are provided in Table F.13, Table F.14, and Table F.15, respectively. The arsenic concentrations are provided on a dry weight (dw) basis.

From Table F.13, it can be seen that for many of the locations, composite samples for lake whitefish were submitted for the bioaccessibility testing. In Baker Creek, the arsenic concentrations ranged from 0.43 mg/kg to around 1 mg/kg, and the bioaccessibility ranged from 42% to 137%. There were 2 samples with arsenic bioaccessibility values that were reported as 120 % and 137%, and these samples were not considered in the evaluation. The average bioaccessibility of the remaining fish samples in Baker Creek was 78%. In Back Bay, the arsenic concentrations ranged from 0.45 mg/kg to 1.6 mg/kg, and the bioaccessibility ranged from 54% to 127%. The one sample with a bioaccessibility of 127% was not considered. The average bioaccessibility for lake whitefish in Back Bay was 71%. In Mosher Island (South Yellowknife Bay), the arsenic concentrations ranged from 0.47 mg/kg to 1.5 mg/kg and the bioaccessibility ranged from 25% to 102%. The average bioaccessibility for lake whitefish in South Yellowknife Bay was 70%, which is the same as in Back Bay. At the background location (Horseshoe Island), the arsenic concentrations ranged from 0.3 mg/kg to 0.76 mg/kg, and the bioaccessibility ranged from 46% to 119%. The average bioaccessibility for lake whitefish in background was 72%, which is the same as in Back Bay.

From Table F.14, it can be seen that in Baker Creek the arsenic concentrations in northern pike ranged from 1.1 mg/kg to 2.3 mg/kg, and the bioaccessibility ranged from 20% to 58%. The average bioaccessibility of northern pike in Baker Creek was 44%. In Back Bay, the arsenic concentrations ranged from 0.72 mg/kg to 1.2 mg/kg, and the bioaccessibility ranged from 32% to 90%. The average bioaccessibility for northern pike in Back Bay was 64%. In Mosher Island (South Yellowknife Bay), the arsenic concentrations ranged from 0.88 mg/kg to 1.4 mg/kg, and the bioaccessibility ranged from 40% to 86%. The average bioaccessibility for northern pike in South Yellowknife Bay was 57%. At the background location (Horseshoe Island), the arsenic concentrations ranged from 0.47 mg/kg to 0.87 mg/kg, and the bioaccessibility ranged from 64% to 87%. The average bioaccessibility for northern pike in background was 78%.

From Table F.15, it can be seen that there are no samples of inconnu from Baker Creek and Back Bay. In Mosher Island (South Yellowknife Bay), the arsenic concentrations ranged from 0.23 mg/kg to 0.48 mg/kg. The bioaccessibility for the inconnu samples were all below detection limits, and the only value reported was 39%. At the background location (Mackenzie Island), the arsenic concentrations ranged from 0.38 mg/kg to 0.62 mg/kg and the bioaccessibility ranged from 33% to 51%. The average bioaccessibility for inconnu from background (Mackenzie Island) was 38%.

Table F.16 provides as summary of the bioaccessibility values for the large-bodied fish at the Baker Creek outlet and locations in Yellowknife Bay. For the ecological risk assessment, the average bioaccessibility values at the various locations were used. The average bioaccessibility for all the fish samples in Baker Creek is 61%. For Back Bay, the average bioaccessibility was 68% and for South Yellowknife Bay and background the average bioaccessibility is 55% and 62%, respectively.

Table F.16 Summary of average arsenic bioaccessibility values for all the fish species and locations

Inconnu				
% Bioaccessibility	NA	NA	39	37

F.3.4 Bioaccessibility in Vegetation at Giant Mine

As part of the data gaps analysis for the risk assessment, it was determined that additional vegetation data as well as bioaccessibility information was needed for vegetation present on Giant Mine. This information is very helpful for the ecological risk assessment, as animals consume plants. Golder collected this additional information in the summer of 2016 and provided the results in a technical memo entitled *Giant Mine Data Report-Human Health and Ecological Risk Assessment Data Gaps* (Golder 2016b). Leaves of cranberry and alder were collected to represent terrestrial forbs and shrubs. Five alder samples and five cranberry samples were sent to RMC for bioaccessibility analysis. Figure F.12 provides a map of indicating the locations of the alder and cranberry samples that were sent for bioaccessibility testing and Table F.17 provides a summary of the bioaccessibility results for the alder and cranberry leaves at the Giant Mine. The concentrations are provided on a wet weight (ww) basis.

As seen from the table, the arsenic concentrations in the vegetation ranged from 0.9 mg/kg ww to 35 mg/kg ww and the % bioaccessibility ranged from 14% to 56%. The average bioaccessibility of the ten samples is 34%. This value was used for all vegetation on the Giant Mine, as this was considered to be a reasonable representation of the availability of arsenic in plants. Koch et al. (2013) carried out some analyses of cranberry and Labrador tea samples from the Giant Mine. Four samples (two cranberry and two Labrador tea) in all were analyzed for bioaccessibility. The two cranberry samples had bioaccessibilities of 19% and 60% and the Labrador tea samples had lower bioaccessibility values of 10% and 17%. The average of these four plant samples is around 27%, which is in line with the 34% bioaccessibility value that is being used in this report for vegetation at the Giant Mine. For the consumption of Labrador tea, an average bioaccessibility of the two samples of 15% has been used.

Figure F.12 Map showing locations of bioaccessibility samples for alder and cranberry leaves at Giant Mine

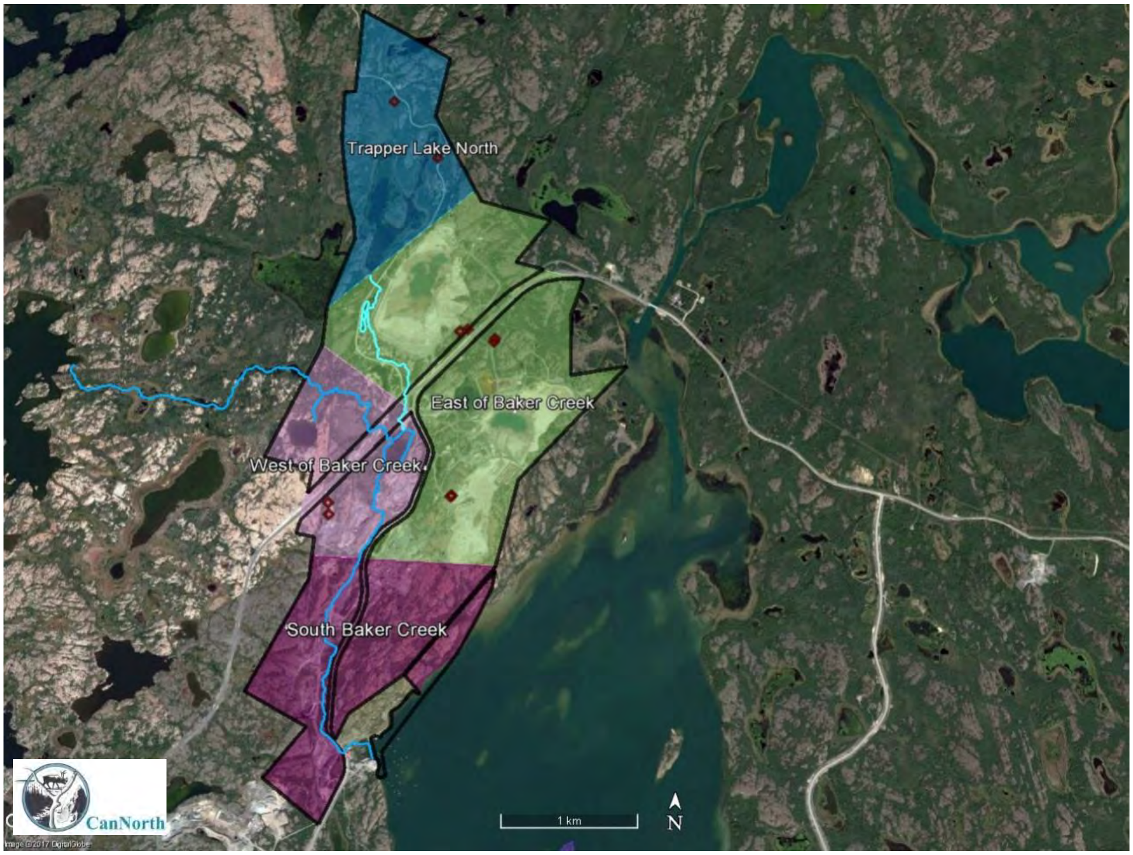

Table F.17 Summary of arsenic bioaccessibility results for alder and cranberry leaves at Giant Mine

Sample ID	Location	Plant Type	BA Conc. (mg/kg ww)	Foliage Conc. (mg/kg ww)	% As BA
16-Giant -AL-BIO-01	Trapper Lake	Alder Leaves	0.7	1.6	44
16-Giant -AL-19-BIO	West Baker Creek	Alder Leaves	0.6	1.4	43
16-Giant -AL-51-BIO	Near North Tailings Pond	Alder Leaves	2.2	15	14
16-Giant -AL-60-BIO	Near North west Tailings Pond	Alder Leaves	1.1	5.9	19
16-Giant -AL-61-BIO	East Quadrant	Alder Leaves	0.87	3.5	25

16-Giant -CR-61-BIO	East Quadrant	Cranberry Leaves	1.4	5.9	24

Note: The average bioaccessibility of the alder and cranberry leaves at the Giant Mine is 34%.

F.3.5 Bioaccessibility in Hare and Mushrooms

Koch et al. (2013) carried out some analyses of hare samples obtained from contaminated and uncontaminated sites in Yellowknife. Four hare samples were obtained from contaminated areas and three hare samples were obtained from uncontaminated areas and all were analyzed for bioaccessibility using the physiologically-based extraction test (PBET) method. Table F.18 provides a summary of the results from the Koch et al. (2013) paper. As seen from the paper, the highest bioaccessibility of hare in contaminated areas was 54%, and the highest bioaccessibility of hare in uncontaminated areas was 76%. Koch et al. (2013) noted that about 56% of the arsenic in the hare in the uncontaminated area was arsenobetaine. As seen from the table, the PBET testing considered gastric and gastric plus intestional bioaccessibility; however, there was no significant difference between the two methods and, therefore, all samples were considered. For the purposes of the risk assessment, an average bioaccessibility of 38% was used to represent small mammals (hare) on contaminated areas and an average bioaccessibility of 50% was used to represent small mammals (hare) from uncontaminated areas. Analyses were also conducted for hares from uncontaminated areas in Nova Scotia, and an average bioaccessibility of 49% was reported. In the absence of data for other animals, a bioaccessibility of 50% was used to represent the bioaccessibility in the flesh of moose, grouse, hare, duck/goose, muskrat, beaver, and grouse.

Table F.18 Summary of arsenic bioaccessibility results for hare from Yellowknife area

Sample	Location	BA Conc. (mg/kg ww)	Hare As Conc. (mg/kg ww)	% As BA
CYK12010G	Yellowknife, Contaminated	0.32	0.6	52

UCYK12000GI	Yellowknife, Uncontaminated	0.078	0.102	76
UCYK22000G	Yellowknife, Uncontaminated	<0.02	0.016	-
UCYK22000GI	Yellowknife, Uncontaminated	<0.02	0.016	-

Note: G – Gastric; GI – gastric+intestinal.

Koch et al. (2013) also conducted bioaccessibility tests on mushrooms from the Yellowknife area. Table F.19 presents a summary of the results. As seen in the table, the PBET testing considered gastric and gastric plus intestinal bioaccessibility; however, there was no significant difference between the two methods and, therefore, all samples were considered. The average bioaccessibility for mushrooms of 70% was used in the assessment.

Table F.19 Summary of arsenic bioaccessibility results for mushrooms from Yellowknife area

Sample	Mushroom As Conc. (mg/kg ww)	BA Conc. (mg/kg ww)	% As BA
BoleteYKG	2.3	1	45

Agaricussp.YK4GI	4.2	3.6	84

Note: G – Gastric; GI – gastric+intestinal.

F.3.6 Summary of Arsenic Bioaccessibility Values Used in the HHRA

Based on the bioaccessibility values provided in the sections above, the specific assumptions for arsenic bioavailability for the HHRA are provided in Table F.20. The soil bioaccessibility values for Long Lake and the former Townsite were all based on soil samples collected in those areas. For the Giant Mine site, the remedial plans indicate that an area of the site with arsenic concentrations above 3,000 mg/kg will be fenced. This area contains the disturbed soils and, thus, only the undisturbed soils represent exposure for humans. Thus, a bioaccessibility of 38% representing undisturbed soils was used. Dust was assumed to have the same bioaccessibility as soil.

For sediments, the bioaccessibility was based on measured data for Long Lake and the Townsite. For the rest of Yellowknife Bay, it was assumed that the bioaccessibility in the Townsite sediments was representative. This value seems reasonable, as it is lower than the sediments in Long Lake and the undisturbed soils at the Giant Mine.

For fish, it was assumed for lake whitefish, inconnu, and lake trout that the bioaccessibility was represented by the average value for all fish analyzed in Yellowknife Bay (e.g., Back Bay, Mosher Island, and background locations).

For medicinal tea, mushrooms, and hare, the bioaccessibility values were obtained from the literature for samples collected in the Yellowknife area (Koch et al. 2013). In the absence of data for other animals, it was assumed that the bioaccessibility of arsenic in the hare of 50% was considered to be representative.

The bioaccessibility of arsenic in other media (e.g., water, air, berry, organs, and lake trout) was assumed to be 100% in the absence of other information.

Table F.20 Summary of arsenic bioaccessibility assumptions for HHRA

Media	Location	Bioavailability Assumption	Rationale	Data Reference
Soil/Dust	Fred Henne Campground	36%	Average of five samples from Fred Henne Campground	Site-specific Golder (2016a), Table 17
	Townsite	30%	Average of eight samples from Townsite	Site-specific Golder (2016a), Table 4
	Giant	38%	Average of nine samples representative of undisturbed soils	Site-specific Golder (2016a)
	All off-site locations including Background	38%	Assumed to be represented by undisturbed soils	-
Sediment	Long Lake	45%	Average of five samples from Long Lake	Site-specific Golder (2016b), Table 17

	Yellowknife Bay, including BG	26%	Assume same as shoreline Townsite sediments since in Yellowknife Bay	-
Lake Whitefish	All	73%	Average of Back Bay, Mosher Island, and Background	Site-specific Stantec (2014), Appendix C
Inconnu	All	38%	Average of Mosher Island and Background	Site-specific Stantec (2014), Appendix C
Northern Pike	All	67%	Average of Back Bay, Mosher Island, and Background	Site-specific Stantec (2014), Appendix C
Medicinal Tea	All	15%	Average of two samples from literature for Yellowknife area.	Koch et al. (2013)
Mushroom	All	70%	Average of 10 samples from literature for Yellowknife area.	Koch et al. (2013)

Media	Location	Bioavailability Assumption	Rationale	Data Reference
Hare	All	50%	Average of hare muscle from uncontaminated areas from literature for Yellowknife area	Koch et al. (2013)
Moose	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area	Koch et al. (2013)
Grouse	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area	Koch et al. (2013)
Duck	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area	Koch et al. (2013)
Muskrat	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area	Koch et al. (2013)
Beaver	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area	Koch et al. (2013)
Goose	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area	Koch et al. (2013)

F.4 Arsenic Speciation

Chemicals such as arsenic are found in different forms in the environment. Speciation is the process of determining the proportions of actual chemical forms in a sample, since the chemical form can affect the bioavailability and relative toxicity of the chemical. For example, in fish, there are many forms of arsenic both in an inorganic and organic form. Many forms of inorganic arsenic are considered to be toxic (see Appendix G); however, arsenobetaine (an organic form of arsenic) is considered to be the non-toxic (ATSDR 2007). The incorporation of speciation information in fish and other plants helps to increase the accuracy of, and confidence in, the health risk predictions. The discussion below focuses on arsenobetaine, as all other arsenic species are considered to be as toxic as inorganic arsenic.

The summaries presented in the section focus on the portion of arsenobetaine found in fish species as well as mushrooms. This portion of arsenic assumed to be present as arsenobetaine was removed from the arsenic concentration in order to more accurately represent the potential risks from consumption of arsenic in fish and mushrooms. Arsenobetaine speciation data were available for the fish species lake whitefish, inconnu, and northern pike as well as for mushroom. There were no data on arsenic speciation in lake trout and, therefore, it was assumed that none of the arsenic present was in the form of arsenobetaine.

F.4.1 Arsenobetaine Speciation in Fish

In addition to bioaccessibility data, Stantec (2014) also provides arsenobetaine speciation data for large-bodied fish. The results of the arsenobetaine speciation testing for lake whitefish, northern pike, and inconnu are provided in Table F.13, Table F.14, and Table F.15, respectively. The concentrations are provided on a dw basis.

From Table F.13, it can be seen that, for many of the locations, composite samples for lake whitefish were submitted for the speciation testing. In Baker Creek, the arsenic concentrations ranged from 0.43 mg/kg to around 1 mg/kg, and the arsenobetaine ranged from 50% to 145%. There were two samples with arsenobetaine values that were over 100%, and these samples were not considered in the evaluation. The average % arsenobetaine of the remaining fish samples in Baker Creek was 67 %. In Back Bay, the arsenic concentrations ranged from 0.45 mg/kg to 1.6 mg/kg, and the % arsenobetaine ranged from 38% to 95%. The average % arsenobetaine for lake whitefish in Back Bay was 65%, which is the similar to Baker Creek. In Mosher Island (South Yellowknife Bay), the arsenic concentrations ranged from 0.47 mg/kg to 1.5 mg/kg and the % arsenobetaine ranged from 7% to 78%. The average % arsenobetaine for lake whitefish in South Yellowknife Bay was 59%. At the background location (Horseshoe Island), the arsenic concentrations ranged from 0.3 mg/kg to 0.76 mg/kg, and the % arsenobetaine ranged from 31% to 58%. The average % arsenobetaine for lake whitefish in background was 43%.

From Table F.23, it can be seen that there are no samples of inconnu from Baker Creek and Back Bay. In Mosher Island (South Yellowknife Bay), the arsenic concentrations ranged from 0.23 mg/kg to 0.48 mg/kg. The % arsenobetaine for the inconnu samples were all below detection limits with the exception of three samples with an average % arsenobetaine of 26%. At the background location (Mackenzie Island), the arsenic concentrations ranged from 0.38 mg/kg to 0.62 mg/kg, and the % arsenobetaine ranged from 18% to 24% with two samples below detection limits. The average % arsenobetaine for inconnu in background was 20%.

Table F.24 provides as summary of the average % arsenobetaine values for the large-bodied fish at the Baker Creek outlet and locations in Yellowknife Bay. For the ecological risk assessment, the average % arsenobetaine values at the various locations were used. The average % arsenobetaine for all the fish samples in Baker Creek is 46%. For Back Bay, the average % arsenobetaine was 54%, and for South Yellowknife Bay and background, the average % arsenobetaine is 38% and 36%, respectively.

Table F.24 Summary of average arsenobetaine speciation for all the fish species and locations

Location	Baker Creek Outlet	Back Bay	Mosher Island	Background
Lake Whitefish				
% Arsenobetaine	67	65	59	43
Northern Pike				
% Arsenobetaine	24	43	29	44
Inconnu				
% Arsenobetaine	NA	NA	26	20

F.4.2 Speciation in Wildlife and Mushrooms

Koch et al. (2013) also conducted speciation tests on mushrooms from the Yellowknife area. Table F.25 presents a summary of the results for arsenobetaine, which is considered to be the non-toxic form of arsenic. As seen in the table, for most of the samples the % arsenobetaine ranges between 38% and 43%. For two samples, the % arsenobetaine was under 10%. The average % arsenobetaine for mushrooms of 33% was used in the assessment.

Table F.25 Summary of arsenobetaine concentrations in mushrooms from Yellowknife area

Sample	Mushroom As Conc. (mg/kg ww)	Arsenobetaine Conc. (mg/kg ww)	% As BA
Agaricussp.YK1G	4.8	0.43	9
Agaricussp.YK1GI	4.8	0.38	8
Agaricussp.YK2G	1.2	0.49	40
Agaricussp.YK2GI	1.2	0.51	43
Agaricussp.YK3G	2.7	1.3	48
Agaricussp.YK3GI	2.7	1.1	41
Agaricussp.YK4G	4.2	1.6	38
Agaricussp.YK4GI	4.2	1.7	40

Note: G – Gastric; GI – gastric+intestinal; average % arsenobetaine was 33%.

F.4.3 Summary of Arsenobetaine Values Used in the HHRA

The specific assumptions for arsenic speciation with respect to arsenobetaine content for use in the HHRA are provided in Table F.26. As seen from the table, for lake whitefish, northern pike, and inconnu, the % arsenobetaine was represented by the average % arsenobetaine from all locations in Yellowknife Bay (Back Bay, Mosher Island, and background locations).

For mushrooms, the % arsenobetaine was based on literature values pertaining to samples collected in the Yellowknife area. For all other samples, speciation of arsenic was not accounted for.

Table F.26 Summary of arsenic speciation assumptions

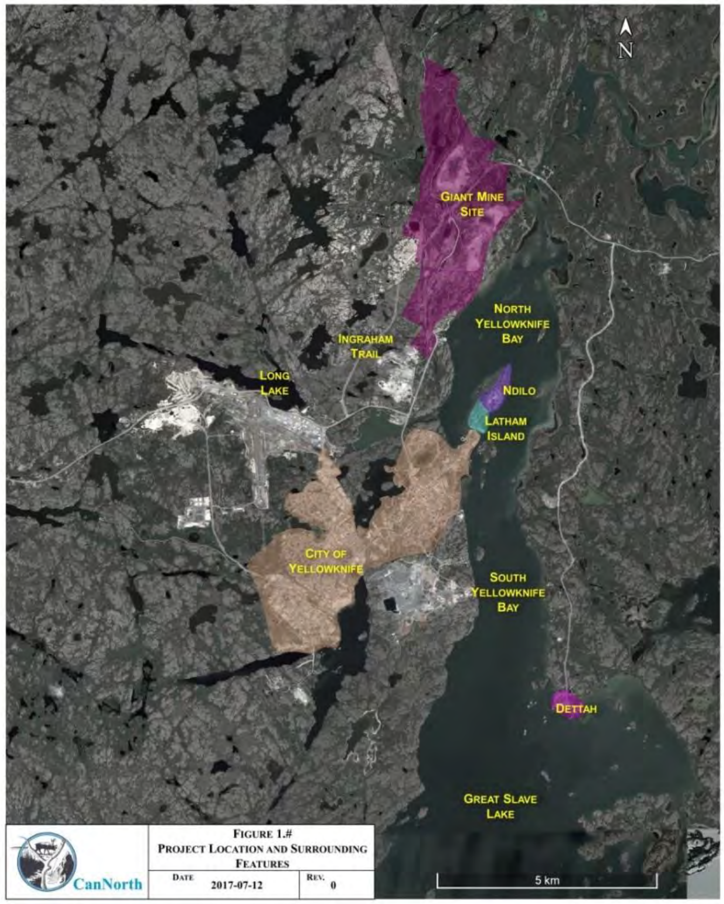
Media	Location	Arsenobetaine Assumption	Rationale	Data Reference
Lake Whitefish	All	59%	Average of Back Bay and Mosher Island	Stantec (2014), Appendix C
Inconnu	All	23%	Average of Mosher Island and Background	Stantec (2014), Appendix C
Northern Pike	All	35%	Average of Baker Creek Outlet, Back Bay, Mosher Island, and Background	Stantec (2014), Appendix C
Mushroom	All	33%	Average of eight samples	Koch et al. (2013)

F.5 Exposure Point Concentrations

Exposure point concentrations (EPCs) are estimations of the concentration of a chemical in the environment and are generally a conservative estimate of the average chemical concentration in the environment.

The developed EPCs for each location considered for the HHRA are provided in the following sections. Figure F.13 shows the locations considered in the development of the EPCs.

Figure F.13 Locations considered for the development of EPCs



F.5.1 Current

Available site data and details on the data handling are provided in Appendix B. For the purposes of determining EPCs, the United States Environmental Protection Agency (U.S. EPA 2002) recommends the 95% UCLM as being a reasonable estimate of the concentration that an individual will likely be exposed to over time. For Detailed Quantitative Human Health Risk Assessments, Health Canada also supports the use of the 95% UCLM (Health Canada 2010a). Thus, for the HHRA, this statistic was used as the EPC where sufficient data are available. The approach for developing the EPCs for all media (other than food) at the various HHRA receptor locations are as follows:

- If a sufficient number of samples was available (i.e., 10 or more samples), the 95% UCLM was selected as the EPC, which is considered to be a reasonable estimate of what the receptor will be exposed to over time.

- If there were insufficient samples (i.e., less than 10), the 95th percentile or the maximum concentration was selected as the EPC on a case-by-case basis after examination of the data.

The 95% UCLM was calculated using ProUCL, which is a statistical program that provides 95% UCLM recommendations (based on data distribution, data set size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate; in these cases, the highest appropriate 95% UCLM was selected. It is noted that the CCME (2016) suggest that the BCA bootstrap approach from ProUCL can be used for the majority of datasets; the selection of the highest 95% UCLM that may be greater than the BCA bootstrap recommendation is, therefore, a conservative approach.

Country Food

All receptor locations were assumed to consume country food at the same EPCs derived from measured concentrations. Measured concentrations were based on the results of the voluntary samples that were collected (Appendix B) and are presented in Table F.27. In the case of country food, the average concentrations were used with the exception of fish where there was a large number of samples and the 95%UCLM was used. For berries and fish, assumptions were made related to where each receptor location would source these food items; these assumptions are outlined in Appendix E. The gathering location map for berries is provided in Figure F.14, and the fishing location map is provided in Figure F.15. Figure F.16 shows a summary of the locations of the voluntary samples within 50 km of the site. Fish samples were represented by whitefish as the measured concentrations of lake trout and inconnu (which are also reported to be eaten) were similar. Therefore, lake whitefish was used as a surrogate for consumption of fish. Figure F.17 provides a schematic representation of the concentrations of arsenic, antimony, and manganese in country food in comparison to background.

Table F.27 Summary of EPCs – country food

Country Food	Location	Concentration (mg/kg ww)			Statistic	Remarks
		Arsenic	Antimony	Manganese		
Berries	Ndilo	0.11	0.007	16.1	Average	Average of six samples including raspberries, Saskatoon berries and rose hips
	T1 (incl. Ndilo)	0.11	0.004	17.5	Average	Average of 14 samples including cranberries, raspberries, Saskatoon berries and rose hips
	Beyond T1	0.04	0.001	20.2	Average	Average of six samples including five cranberry and one raspberry sample
Fish	North Yellowknife Bay (A2)	0.21	0.03	0.15	95% UCLM except Antimony (MDL)	Assumed to be represented by 36 whitefish samples
	South Yellowknife Bay (A3)	0.18	0.03	0.15	95% UCLM except antimony (MDL), manganese (95th percentile)	Assumed to be represented by 21 whitefish samples
Moose	Measured	0.04	0.002	0.25	Average	Average of five samples
Hare	Measured	0.10	0.01	0.19	Average	Average of five samples
Ptarmigan/ Grouse	Measured	0.04	0.015	0.39	Average except arsenic (geomean)	Average of nine samples; arsenic concentration is based on the geometric mean due to the skewed data set
Duck/Goose	Measured	0.05	0.002	0.53	Average for duck and goose	Average of four samples
Muskrat/ Beaver	Measured	0.03	0.01	0.21	Average of beaver and muskrat	Average of four samples

Note: T1 is within 10 km of the site.

Figure F.14 Hunting/trapping/gathering location reference map

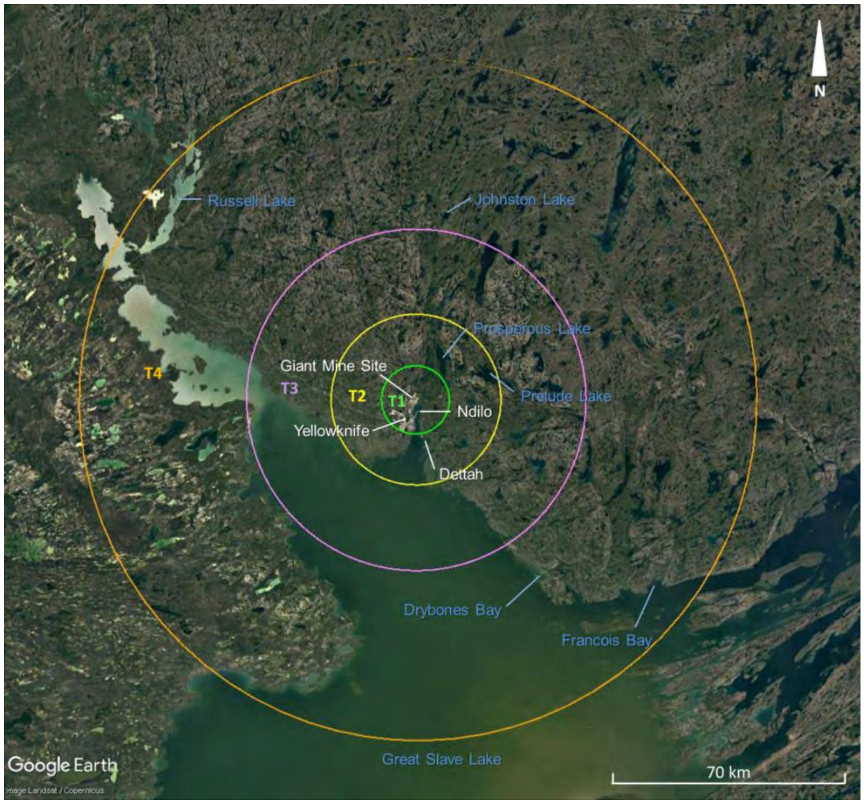


Figure F.15 Fishing location reference map

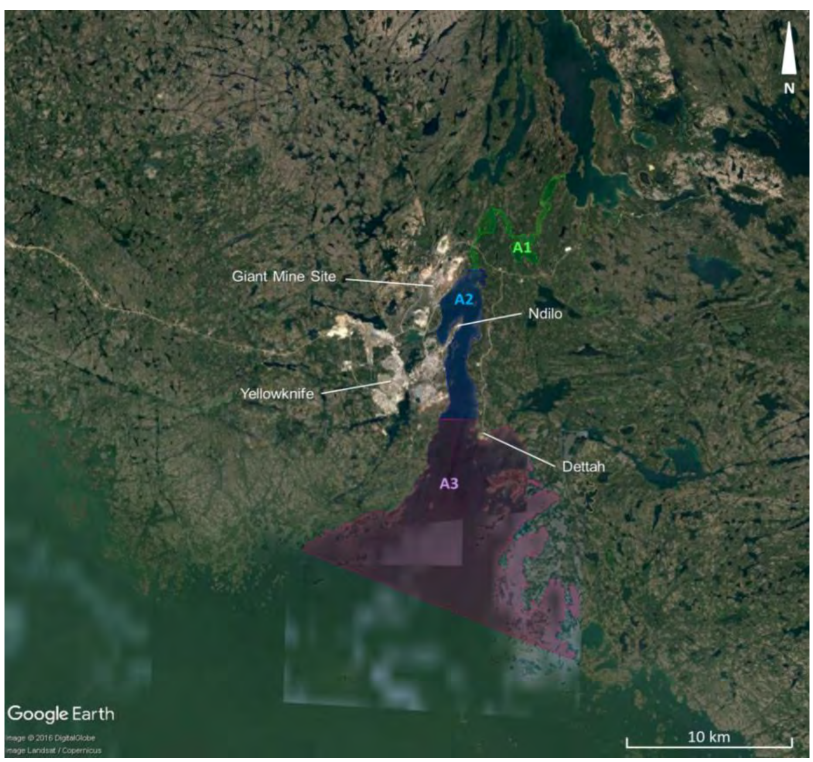

Figure F.16 Voluntary Samples from within 50 km of the Giant Mine

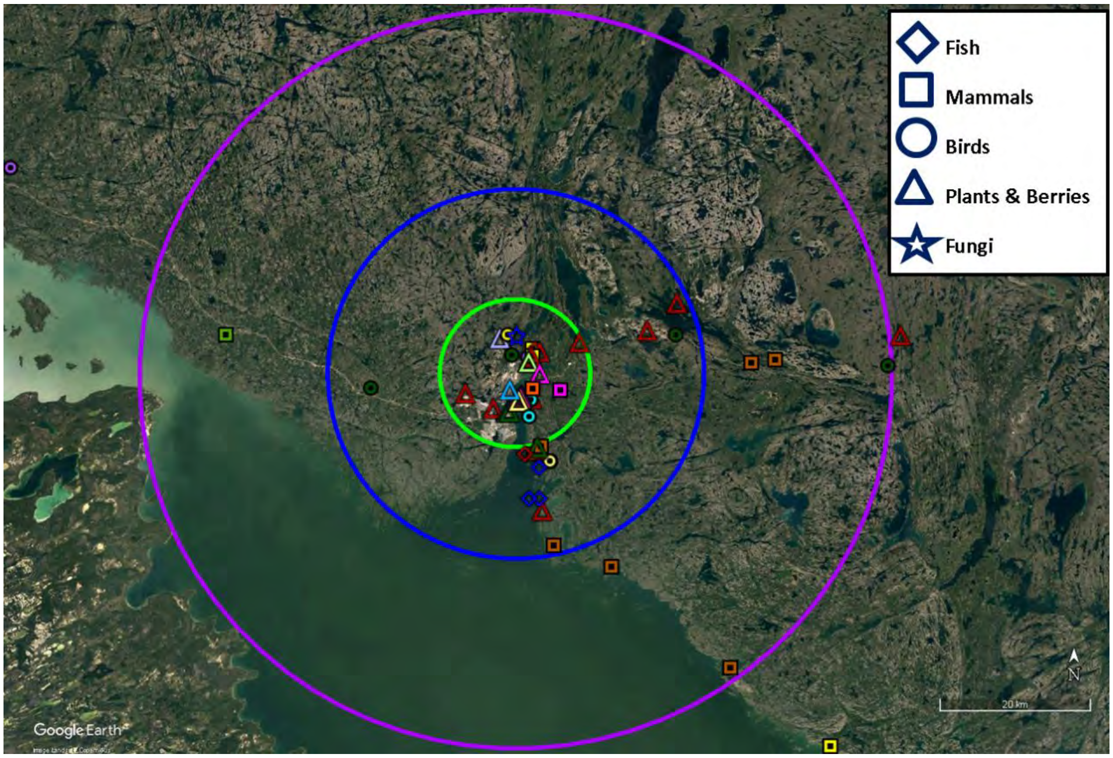

Figure F.17 Schematic representation of concentrations in country foods as compared to background

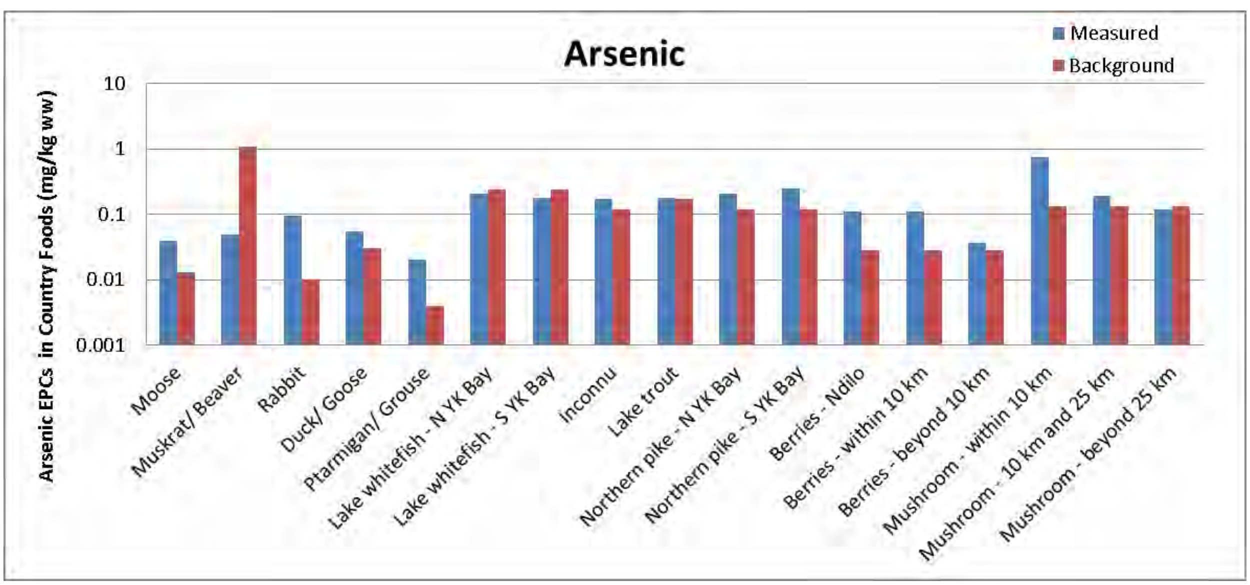
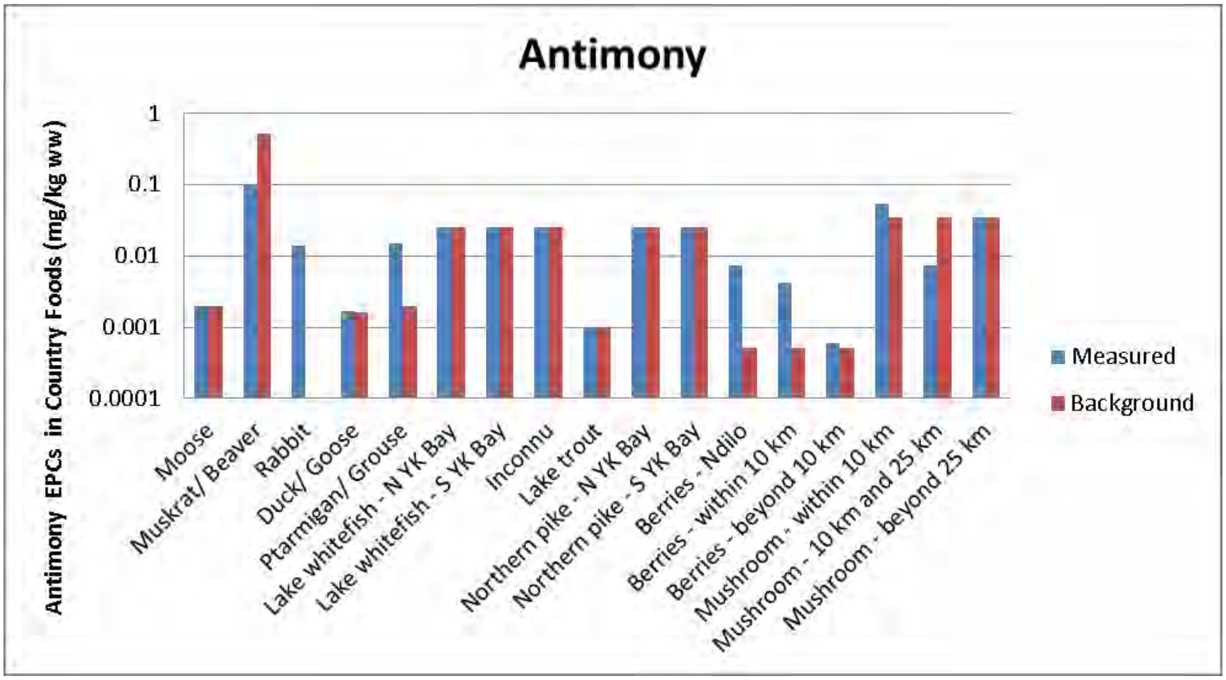
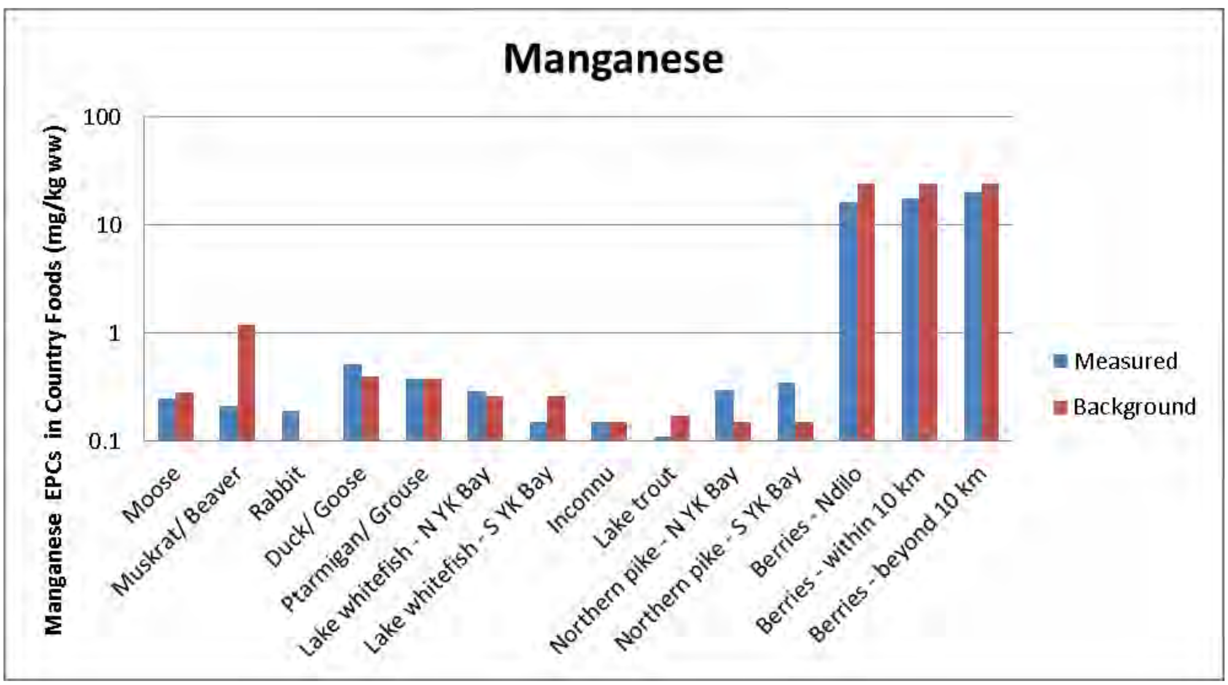






The EPCs considered for the additional assessments for medicinal tea, ingestion of mushrooms, organ consumption, and berries from the Giant Mine (for the future scenario) are summarized in Table F.28.

Table F.28 Summary of EPCs – additional assessments for country food

Media	Location	Concentration (mg/kg ww)			Statistic
		Arsenic	Antimony	Manganese	
Berries (Future)	Giant Mine	6.4	0.54	269	95% UCLM of berry shoots and leaves
Medicinal Tea	All Areas (incl. Ndilo)	0.48	0.04	188	Average of four samples
Mushroom	City of YK	See Appendix P			
Organ - Moose	All Areas	0.007	0.001	1.2	Max of one heart and one liver sample
Organ – Fish Liver	North YK Bay (A2)	0.32	0.02	1.2	Average of 20 samples
	South YK Bay (A3)	0.15	0.03	1.2	Average of 40 samples
Organ – Ptarmigan Heart	All Areas	0.09	0.002	0.51	Average of nine heart samples
Organ – Ptarmigan Gizzard and Liver	All Areas	1.1	0.007	10.7	Average of nine gizzard and liver samples
Organ – All	All Areas	0.24	0.02	1.8	Weighted (by ingestion rate) average of moose organs, fish livers, and ptarmigan heart, gizzard, and liver)

A number of sensitivity assessments were completed related to country foods. The sensitivity analyses only focused on arsenic. The two scenarios that result in changes to the EPCs for country food are:

- Country food – Average concentrations of arsenic were used in the assessment as shown in Table F.27, as it was unlikely that people would eat all their country foods at the maximum concentration. Nonetheless, the use of maximum measured concentrations was considered in the sensitivity assessment (summarized in Table F.29).
- Moose – One moose sample obtained from the voluntary sampling had an arsenic level of 0.65 mg/kg wet weight. This sample was determined to be an outlier. The sensitivity analysis examined the effect of consuming moose meat at this concentration.

Table F.29 Summary of arsenic EPCs – sensitivity assessments for country food

Media	Location	Concentration (mg/kg ww) Arsenic	Statistic	Remarks
Maximum Concentration Assumption				
Moose	All Areas	0.07	Maximum of six samples	Assumes arsenic bioaccessibility assumption of 50%
Hare	All Areas	0.09	Maximum of five samples	Assumes arsenic bioaccessibility assumption of 50%
Ptarmigan/Grouse	All Areas	0.29	Maximum of eight samples	Assumes arsenic bioaccessibility assumption of 50%; arsenic concentration is based on the geometric mean due to the skewed data set
Duck	Measured	0.07	Maximum of five samples for duck and goose	Assumes arsenic bioaccessibility assumption of 50%
Muskrat	Measured	0.06	Maximum of four beaver and muskrat samples	Assumes arsenic bioaccessibility assumption of 50%

F.5.1.1 Exposure Point Concentrations by Location

Air quality monitoring in the area has shown that the concentrations in Yellowknife are similar (see Appendix B), and the values used in the assessment are provided in this section for the various locations.

There are no measured indoor dust samples for use in the HHRA and, therefore, assumptions were made to estimate an indoor dust concentration at the receptor locations. There are a number of published studies that discuss how indoor dust concentrations can be derived from outdoor soil concentrations. Oomen and Lijzen (2004) provides a summary of various research papers, published in the late 1980s to late 1990s, that have reported the contribution of exterior soil to interior house dust. The percent of soil in house dust ranges from 8% (Sterling et al. 1998) to >80% (Hawley 1985). Based on an analysis of these studies, Oomen and Lijzen (2004) conclude that most studies suggest that approximately 30% to 50% of house dust originated from exterior soil. They also note that the U.S. EPA (1998) Integrated Exposure Uptake Biokinetic (IEUBK) model for lead uses a default value of 70% (i.e., 0.7 g soil/g dust), which is based on an analysis of empirical data describing the relationship between soil and dust lead concentrations measured from a variety of residential communities. Based on all of this information, Oomen and Lijzen (2004) indicate that a range of 30% to 70% of exterior soil in house dust is a good estimate for the exposure assessment of house dust.

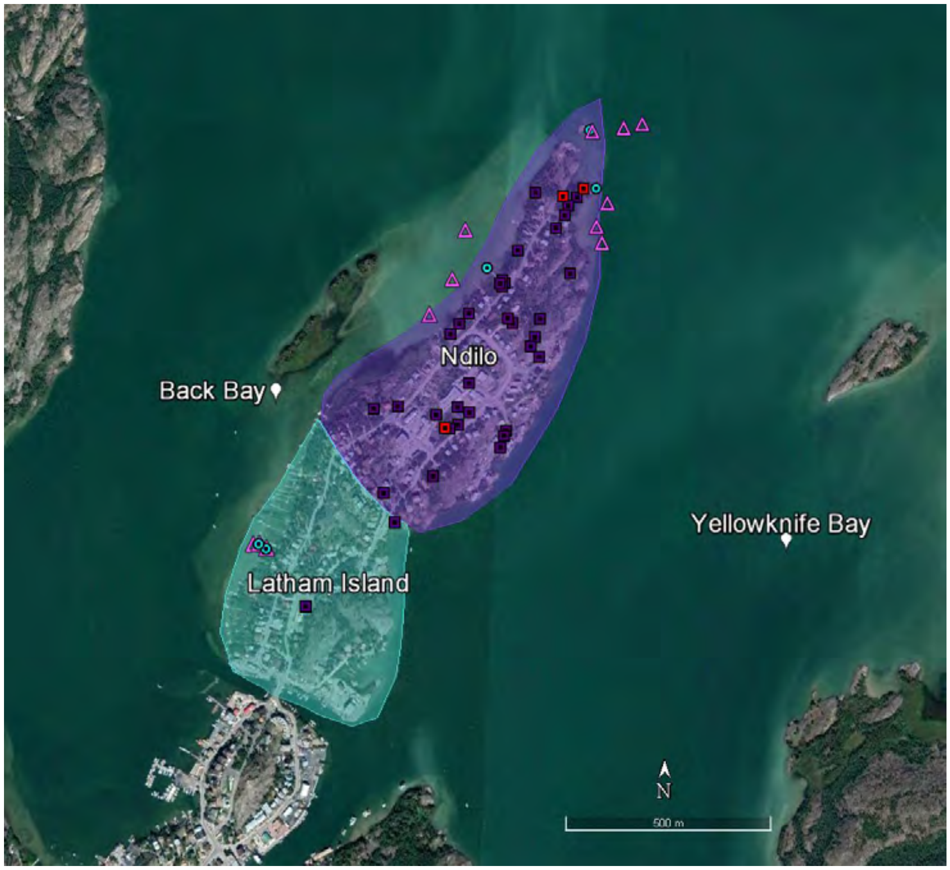
Partridge (2016) conducted studies near a smelter site in Colorado and found that the data from his study demonstrated that only about 32% of the outdoor soil was found in indoor dust, indicating that the IEUBK (U.S. EPA 1998) default assumption of 70% may be conservative. Calabrese and Stanek (1992) also determined that approximately 31% of outdoor soil is found in indoor dust.

Based on this discussion, the default U.S. EPA value of 70% was used to determine the concentration of arsenic, antimony, and manganese in indoor dust from outdoor soil and represents an upper range of the reported literature studies.

Ndilo

The sampling locations for water, soil, and sediments for Ndilo are shown on Figure F.18. As seen from the figure, there is adequate soil coverage to develop a reasonable estimate of soil exposure. It should be noted that the samples shown in the figure only represent shallow soil samples (<10cm depth). Similarily, the sediment samples represent a reasonable estimate of the wading scenario. Yellowknife Bay is quite large and the three sampling locations for water are reasonable. It should be noted that the concentrations of arsenic, antimony, and manganese in North Yellowknife Bay are all below Health Canada drinking water guidelines. The EPCs used in the risk assessment for Ndilo are shown in Table F.31. For soils, there were enough samples that the 95% UCLM was used to represent exposure. For sediment, the exposure was represented by the maximum concentration.

Figure F.18 Sampling locations for water, soil, and sediments in Ndilo



Several arsenic "hot spots" have been identified in soils in the community of Ndilo (indicated in red in Figure F.18 above). Therefore, a sensitivity analysis was conducted to evaluate the impact of remediating the three highest "hot spots" in the Ndilo community. The arsenic concentrations associated with this sensitivity analysis are also included in Table F.31.

Latham Island

The sampling locations for water, soil, and sediments for Latham Island are shown on Figure F.18. As seen from the figure, there are very few samples available. Since Latham Island is so close to Ndilo, the samples were consolidated together to calculate the Latham Island exposure. The sediment samples in Latham Island were specifically collected for the risk assessment to address concerns about children wading at this location. It should be noted that the concentrations of arsenic, antimony, and manganese in Back Bay are all below Health Canada drinking water guidelines.The EPCs used in the risk assessment are shown in Table F.32. There are enough soil and sediment samples that the 95% UCLM was used to represent exposure.

Dettah

The sampling locations for water, soil, and sediments for Dettah are shown on Figure F.19. As seen from the figure, there are not many soil samples available; however, these samples represent the only data that has been collected. The water and sediment samples were considered to be adequate to represent the wading scenario and the drinking water scenario. It should be noted that the concentrations of arsenic, antimony, and manganese in South Yellowknife Bay are all below Health Canada drinking water guidelines. The EPCs used in the risk assessment are shown in Table F.33. There are only a small number of soil samples available at Dettah, and arsenic was the only COPC measured. The two highest arsenic soil concentrations were from the hill in Dettah and the Marina. None of these locations are where people live. Thus, a 95% UCLM was developed to represent the residential exposure scenario in Dettah. The maximum concentration was used to represent the sediment exposure. Two additional soil samples were collected in Dettah as shown in Appendix P.

Figure F.19 Sampling locations for water, soil, and sediments in Dettah

City of Yellowknife

The sampling locations for soil samples for City of Yellowknife are shown on Figure F.20. These locations only represent sampling locations where coordinates are available.

Antimony and manganese EPCs were based on these sampling locations. For arsenic, a total of 260 soil samples were used to develop the EPCs. Thus, the available data represented a reasonable estimate of soil exposures. The EPCs used in the risk assessment are shown in Table F.34. These were represented by the 95% UCLM.

In addition to considering the exposure from living in Yellowknife, additional evaluations were carried out related to camping and swimming/wading activities at the Fred Henne Campground and Long Lake. Figure F.21 shows the locations of the soil, water, and sediment sampling locations, and Table F.35 provides the EPCs used in the assessment. The arsenic soil concentrations at the Fred Henne Campground are below background and, thus, anyone camping at this location will not experience increased risk. The maximum measured sediment concentration was used to represent the exposure while wading and the 95% UCLM of measured water concentrations was used to represent exposure while swimming.

Figure F.20 Soil sampling locations in City of Yellowknife

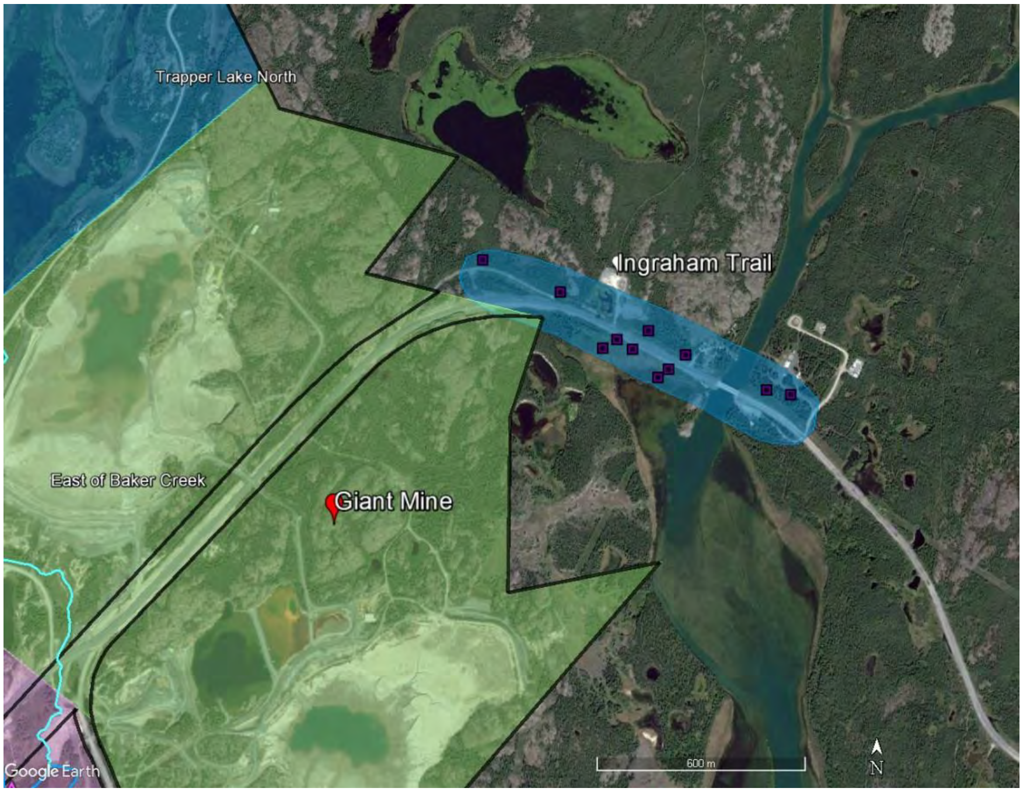
Figure F.21 Soil, water, and sediment sampling locations in Fred Henne Campground and Long Lake

Ingraham Trail

The sampling locations for soil samples for Ingraham Trail near Giant Mine are shown on Figure F.22. These locations are considered to represent exposures for people living along this part of the Trail. The EPCs for soil used in the risk assessment are shown in Table F.36. The 95th percentile value of the data set was used to represent the residential exposure.

Additional soil samples were collected along the Ingraham Trail as part of studies by Queen's University (Jamieson et al. 2017), these locations are shown in Appendix P. As seen from the information in Appendix P, the EPCs developed below are higher than the EPCs with the additional data provided in Appendix P and thus represents a conservative estimate of the EPCs on the Ingraham Trail.

Figure F.22 Soil sampling locations on Ingraham Trail near Giant Mine



Former Townsite

The sampling locations for soil and sediment samples at the former Townsite are shown on Figure F.23. These samples were used to evaluate the unrealistic scenario that someone would live at this location without any remediation. The sediment samples were used to assess a wading scenario. This wading scenario also accounts for someone currently using the boat launch or the nearby marina, as the sediment concentrations were considered to be representative of conditions in those areas. The EPCs used in the risk assessment are shown in Table F.37. The 95% UCLM was used to represent exposures at the Townsite.

Figure F.23 Soil and sediment sampling locations at former Townsite

Drinking Water

All receptor locations were assumed to obtain water from the municipal supply. These concentrations are summarized in Table F.30. Additional assessments were completed for the ingestion of drinking water from South Yellowknife Bay (for Dettah receptors), North Yellowknife Bay (for Ndilo receptors), and Back Bay (for Latham Island receptors). All the concentrations in the table are below the Health Canada drinking water guidelines.

Table F.30 Summary of current EPCs – drinking water

Media	Location	Concentration (mg/L)			Statistic
		Arsenic	Antimony	Manganese	
Drinking Water	Municipal	0.002	0.0002	0.002	95% UCLM except Antimony (Yellowknife River BG, 95%ile)
	South Yellowknife Bay	0.001	0.0001	0.001	95% UCLM
	North Yellowknife Bay	0.002	0.0004	0.003	95% UCLM
	Back Bay	0.002	0.0003	0.003	95% UCLM

Table F.31 Summary of current EPCs – Ndilo

Recreational Soil	2766	162	969	mg/kg dw	Giant Mine	95% UCLM	-

F.5.2 Future

The remedial actions at the site involve the capping of the tailings, the remediation of arsenic concentrations in the disturbed areas of the site to the GNWT industrial criterion, the active management, in the form of excavation and/or fencing, of areas with arsenic concentrations above 3,000 mg/kg, and moving the water treatment discharge pipe to near the mouth of Baker Creek. These remedial activities will not have any effect on the unique location exposures described above. In addition, remedial activities will not impact on the concentrations in the country foods, as none of the samples were obtained from the Giant Mine. The effect of the treated water discharge near the mouth of Baker Creek was evaluated using modelling to determine what the water and sediment concentrations would be in Back Bay and North Yellowknife Bay. It should be noted that the future predicted concentrations are no different that the range of current measured concentrations.

The EPCs associated with future conditions for the assessment are provided in Table F.38. The following sections provide rationale for the derivation of the future EPCs for sediment and soil.

Table F.38 Summary of future EPCs

Media	Concentration			Units	Location	Remarks
	Arsenic	Antimony	Manganese			
Sediment	30	-	-	mg/kg dw	Townsite	Near shore sediments dredged and covered; concentration of 30 mg/kg dw
	40	-	-	mg/kg dw	North Yellowknife Bay	Based on modelling (Appendix K).
Berries	1.1	0.28	350	mg/kg ww	Giant Mine	Calculated using transfer factor approach and remediated soil concentration
Soil	160	16	220	mg/kg dw	Townsite	Soil remediated to GNWT residential criterion
	747	49	1083	mg/kg dw	Giant Mine	Calculated assuming areas with arsenic concentrations greater than 3,000 mg/kg are fenced (inaccessible)

Soil

For the former Townsite, the GMRP indicates that arsenic in the soils will be cleaned up to the GNWT residential criterion of 160 mg/kg. Soil remedial objectives have not been established for antimony and manganese and, thus, assumptions were made as to what the future concentrations will be. Based on the measured soil data (Table F.39) at two locations in the former Townsite where arsenic concentrations are close to the residential GNWT criterion (YK126 and YK302), the antimony soil concentrations are about 10%

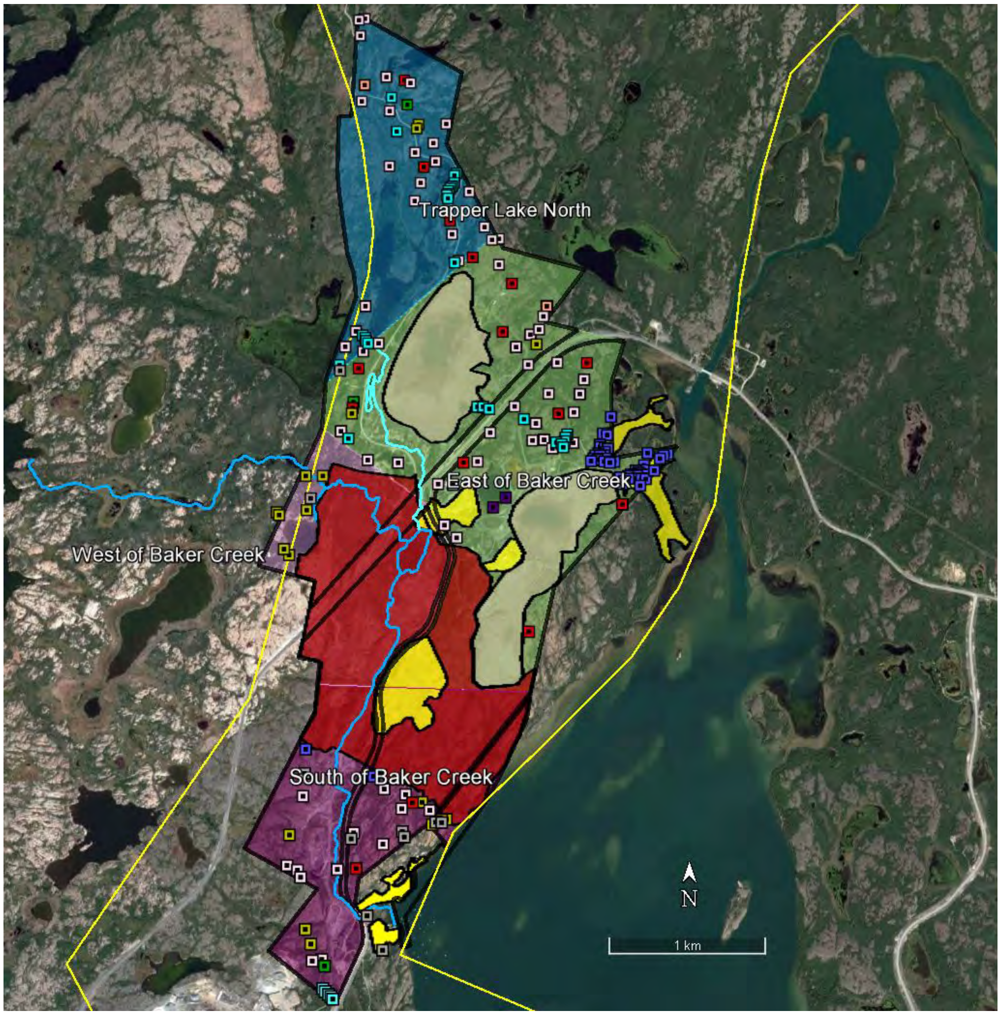
of the arsenic soil concentrations, and manganese soil concentrations are approximately 40% higher than arsenic soil concentrations. Therefore, in the future after remediation, the antimony concentrations at the former Townsite are assumed to be 16 mg/kg and the manganese concentrations 220 mg/kg.

Table F.39 Summary of selected former Townsite soil data

COPC	Concentration (mg/kg dw)	
	YK126	YK302
Arsenic	161	163
Antimony	21	14
Manganese	222	Not available

A recreational scenario was also considered for people going onto the remediated Giant Mine in the future for exercise or other recreational activities. The remedial activities on the site were taken into account in determining the future concentrations of arsenic, antimony, and manganese in the soil. Figure F.24 shows the samples considered in deriving the concentrations at the Giant Mine in the future. For the future scenario, it was assumed that people will not be able to go into the red area, as this area has arsenic concentrations over 3000 mg/kg and will be undergoing active management. The yellow areas on the Giant Mine in Figure F.24 were assumed to be remediated to an arsenic concentration of 340 mg/kg. The tailings were assumed to be covered with rock and to not represent any potential for exposure. No remedial criteria have been developed for antimony and manganese; thus, the future conditions are based on all of the samples shown on Figure F.24. To develop the arsenic concentrations, all the samples shown on Figure F.24 were considered in the data set. In addition, samples in the two yellow areas in East Baker Creek were examined. If the arsenic concentrations exceeded 340 mg/kg, then the concentrations in those samples were adjusted to 340 mg/kg. All other samples with arsenic measured concentrations were left unchanged. The 95% UCLM for arsenic was then derived for the entire dataset, which was considered to represent exposure for someone going on the site to undertake recreational activities. This approach represents an overestimate of the potential exposure, as there are parts of the site that are heavily forested and have wetlands that cannot easily be accessed. For sediments, the GMRP indicates that dredging will occur in the shoreline sediments along the Townsite and near the mouth of Baker Creek. Deeper sediments will be covered. Discussions with the GMRP Team indicated that it is expected that arsenic concentrations in this dredged area would be approximately 30 mg/kg. Table F.38 provides the future EPCs used in the risk assessment.

Figure F.24 Samples considered in deriving future concentrations for HHRA for Giant Mine



F.5.3 Background

Background concentrations for soil, surface water, and sediment were determined as described in Appendix C. Table F.40 provides the EPCs for background used in the assessment.

Table F.40 Summary of EPCs – background

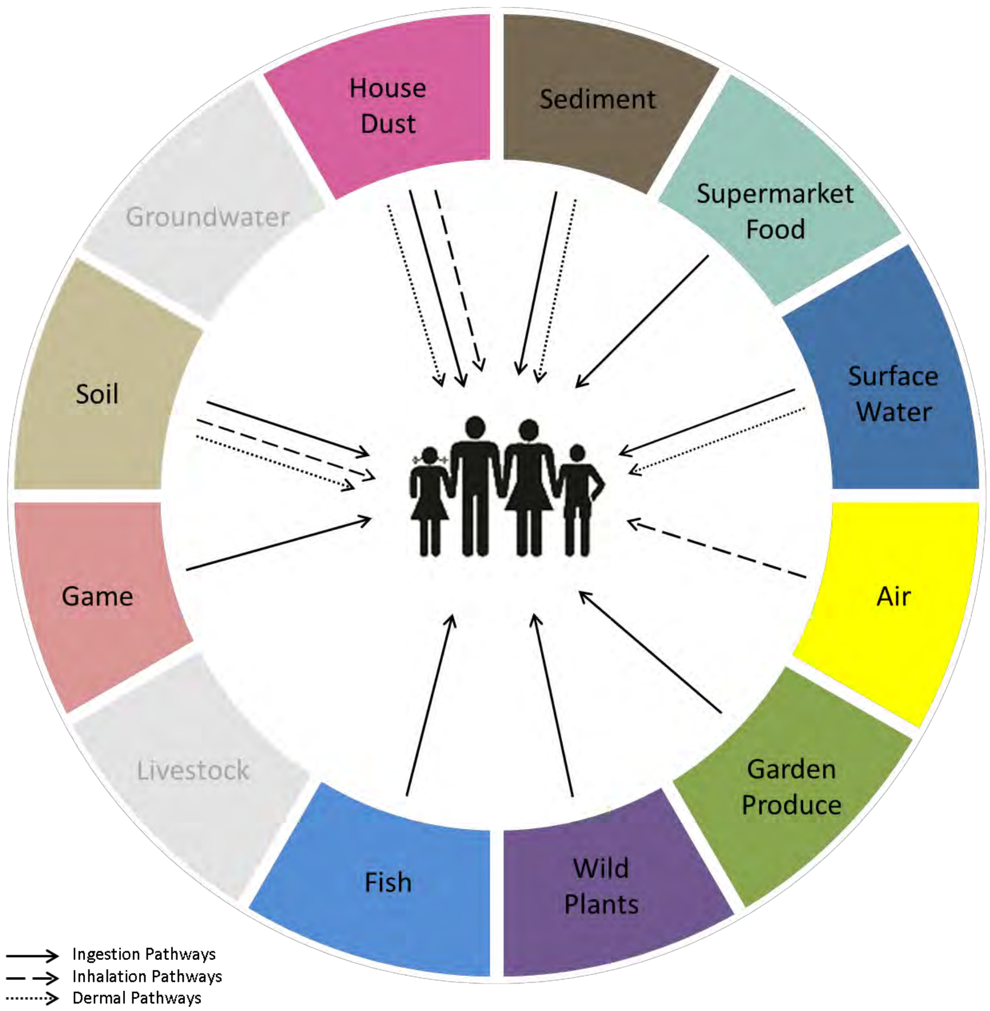
Media	Concentration			Units	Location	Statistic	Remarks
	Arsenic	Antimony	Manganese				
Drinking Water	0.002	0.0002	0.002	mg/L	Municipal	95% UCLM except antimony (Yellowknife River background, 95th percentile)	-
Sediment	23	1.2	434	mg/kg dw	Background	95% UCLM	-
Air	$1x10^{-6}$	0	0	mg/m^3	Background	Mean	Mean background in air in Canada in urban areas
Soil	94	2.2	165	mg/kg dw	Yellowknife Greenstone Belt	95% UCLM except manganese (minimum)	-
	41	0.9	165	mg/kg dw	Regional	95% UCLM except manganese (minimum)	-
Dust	29	2.0	15	mg/kg dw	Regional	-	Factor of 0.7 applied to outdoor soil based on U.S. EPA (1998)
Berries	0.03	0.001	24.4	mg/kg ww	Background	Sample from Tibbit Lake, Ingraham Trail (>50km from site)	-
Mushroom	0.13	0.04	5.9	mg/kg ww	Background	95% UCLM	-
Fish	0.24	0.03	0.26	mg/kg ww	Background	95% UCLM except antimony (Max/95th percentile)	-
Moose	0.01	0.002	0.22	mg/kg ww	Background	Average of two samples > 80 km from site	-
Organ	-	-	-	mg/kg ww	Background	No data	-
Hare	0.02	-	-	mg/kg ww	Background	Lowest measured value except antimony, manganese (no data)	-
Grouse	0.004	0.002	0.38	mg/kg ww	Background	Average of three samples 100 km from site	-
Duck	0.03	0.002	0.40	mg/kg ww	Background	Average for duck and goose	-
Muskrat	1.1	0.53	1.2	mg/kg ww	Background	One sample for beaver from Drybones Bay	-

Note: No data for medicinal tea.

F.6 Equations

The HHRA considered various pathways of exposure, described in Appendix E and illustrated in Figure F.25. The exposure equations used in the assessment are provided in the following section for the human health risk assessment. The exposure assessment considered dermal exposures to dust, soil, sediment, and surface water while swimming and, similarly, ingestion pathways for water, food, soil, incidental sediment, and water ingestion while swimming and wading. The exposure equations used in the assessment were obtained from Health Canada (2010a, 2010b) and are provided below. A sample calculation is provided in Section F.7. The inhalation pathway was assessed via a comparison of air concentrations with reference concentrations for toxicity; therefore, equations for the inhalation pathway are not provided.

Figure F.25 Exposure pathways for HHRA



F.6.1 Dermal Pathways

Dermal exposure for contact with indoor dust, soil, sediment, and water while swimming was calculated using the following equation:

$$I_{dermal}^{media} = \frac{C_{media} \times DLR \times RAF \times ED \times BioA}{BW} \qquad \text{(F-1)}$$

Where:

I_{dermal}^{media}	=	Intake of COPC in media (dust, soil, sediment, surface water) through the dermal pathway (mg/(kg-d))
C_{media}	=	Concentration of COPC in media (dust, soil, sediment) (mg/(kg dw)) or water (mg/L)
DLR	=	dermal loading rate (kg/d or L/hr)
RAF	=	Dermal absorption factor (-)
BW	=	Body weight (kg)
BioA	=	Bioaccessibility assumption (-)
ED	=	Exposure duration, as follows for each media: sediment (7 d/wk per 7 d/wk), dust (7 d/wk per 7 d/wk), soil (7 d/wk per 7 d/wk), recreational soil (2 d/wk per 7 d/wk), swimming (1 hr/d, 3 d/wk per 7 d/wk).

Dermal absorption factors (RAF) are available from literature and are provided in Table F.41 for the COPC considered in the HHRA.

Table F.41 Dermal RAFs

COPC	Dermal RAF	Reference
Arsenic	0.03	Health Canada (2010c)
Antimony	0.1	MOE (2011)
Manganese	0.01	Health Canada (2010c), default

F.6.2 Ingestion Pathways

Water ingestion, as drinking water and incidentally while swimming, was calculated using Equation F-2:

$$I_{wat} = \frac{C_{wat} \times IR_{wat} \times ED}{BW} \qquad \text{(F-2)}$$

Where:

I_{wat}	=	Intake of COPC through the ingestion of water (mg/(kg-d))
C_{wat}	=	Concentration of COPC in water (mg/L)
IR_{wat}	=	Drinking water ingestion rate (L/d) or incidental swimming ingestion (L/hr)
BW	=	Body weight (kg)
ED	=	Exposure duration, as follows for: drinking water (7 d/wk per 7 d/wk), swimming (1 hr/d,, 3 d/wk per 7 d/wk).

Food ingestion was calculated using Equation F-3:

$$I_{foodx} = \frac{C_x \times IR_x \times F_{food} \times BioA}{BW} \qquad \text{(F-3)}$$

Where:

I_{foodx}	=	Intake of COPC through the ingestion of food (mg/(kg-d)), where 'x' is berry, medicinal tea, mushroom, fish, moose, hare, grouse, duck, or muskrat
C_x	=	Concentration of COPC in 'x' (mg/(kg ww))
IR_x	=	Ingestion rate of 'x' ((kg ww)/d)
F_{food}	=	Fraction of time eating food from location (varies)
BW	=	Body weight (kg)
BioA	=	Bioaccessibility assumption (-)

Dust, soil, and sediment ingestion was calculated using Equation F-4:

$$I_x = \frac{C_x \times IR_x \times ED \times BioA}{BW} \qquad \text{(F-4)}$$

Where:

I_x	=	Intake of COPC through the ingestion of x: dust, soil, or sediment (mg/(kg-d))
C_x	=	Concentration of COPC in x: dust, soil, or sediment (mg/(kg dw))
IR_x	=	Ingestion rate of x: dust, soil, or sediment ((kg dw)/d)
BW	=	Body weight (kg)
BioA	=	Bioaccessibility assumption (-)
ED	=	Exposure duration, as follows for each media: sediment (2 hrs/d per 24 hrs/d, 7 d/wk per 7 d/wk), dust (7 d/wk per 7 d/wk), soil (5 d/wk per 7 d/wk), recreational soil (2 d/wk per 7 d/wk).

F.7 Exposure Results

The intakes of arsenic, antimony, and manganese were estimated using the exposure assumptions and equations outlined above. Exposures via the inhalation pathway are not assessed as intakes, but rather in comparison to reference concentrations associated with toxicological effects. Therefore, the inhalation pathway is not included in the following exposure results. The sample calculations provided in Appendix I illustrate that the inhalation pathway is insignificant in the current assessment. Figure F.26 presents a summary of the estimated intakes for arsenic for the typical country food diet receptor from Ndilo. This figure illustrates that the toddler is the most highly exposed life stage. Therefore, for presentation purposes, the estimated intakes for toddlers under the base case scenarios are provided in Figure F.27, Figure F.29, and Figure F.30 for total arsenic, antimony, and manganese, respectively. Estimated intakes for all life stages and scenarios are provided in Table F.42, Table F.43, and Table F.44 for total arsenic, antimony, and manganese, respectively.

Figure F.26 Estimated total arsenic intakes for Ndilo Country Food scenario

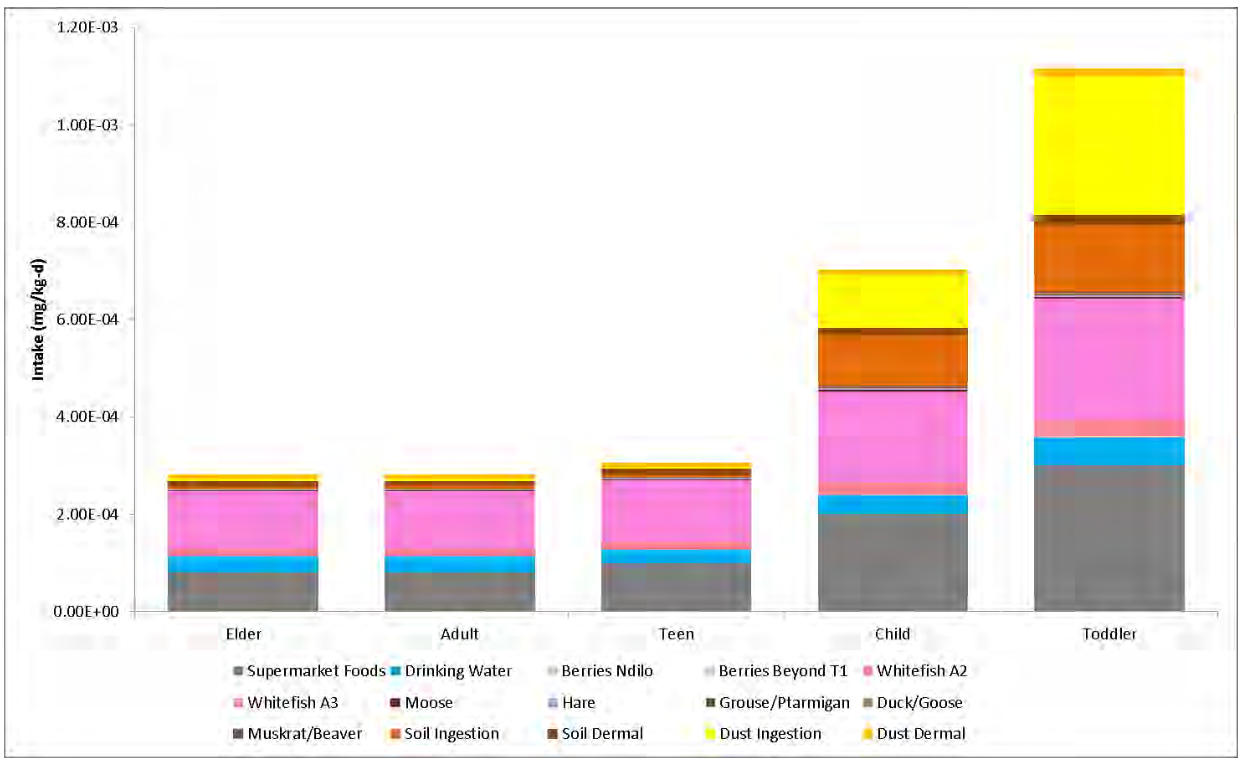


Figure F.27 shows that, after supermarket foods, toddlers are most exposed to arsenic in fish, with soil and indoor dust also contributing to the total intake for arsenic. Intakes to indoor dust and soil vary depending on the receptor location, as arsenic concentrations in soil vary by location. Estimated intakes for all life stages and scenarios are provided in Table F.42.

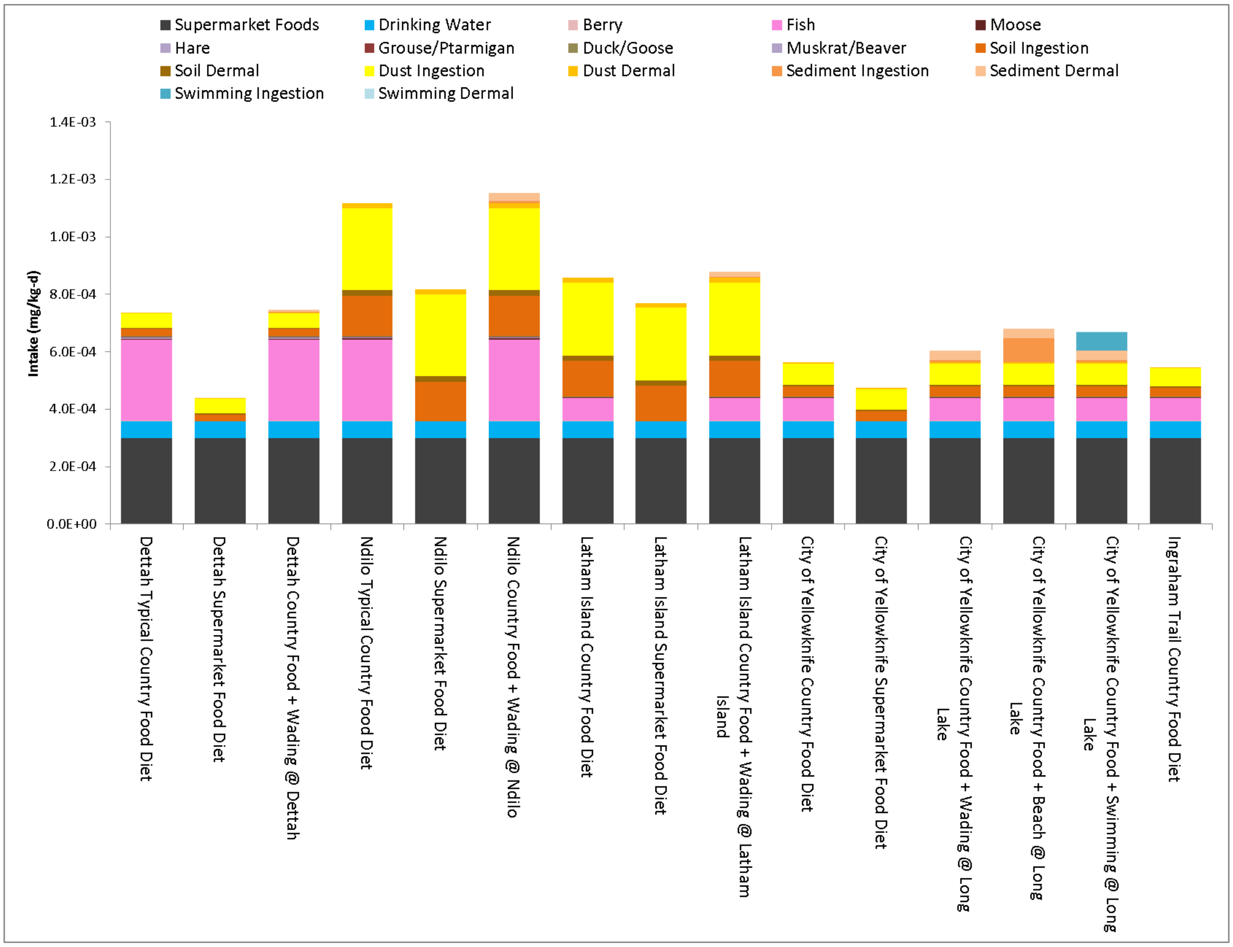
Figure F.27 Estimated intakes for toddler – total arsenic



Because arsenic is evaluated on an incremental basis, Figure F.28 is provided to illustrate the relevant pathways of exposure for incremental arsenic. The incremental arsenic exposure is obtained by subtracting the background arsenic exposure (Figure F.31) from the estimated total arsenic intakes (Figure F.27). Figure F.28 shows that, since a number of the country foods (such as fish) are at background arsenic concentrations, food pathways contribute marginally to the overall incremental intake of arsenic. Table F.45 provides a breakdown of the incremental intakes by food and other ingestion pathways. Thus, at the residential locations, exposures to indoor household dust and soil, through both ingestion and skin contact, dominate the intakes of incremental arsenic by the toddler receptor. For the wading or beach scenarios, dermal contact with sediment is shown to contribute to the intake of incremental arsenic, as does the ingestion of water at

Long Lake for the swimming scenario. These exposures will not be altered by any of the remedial activities at the Giant Mine.

Figure F.28 Estimated intakes for toddler – incremental arsenic

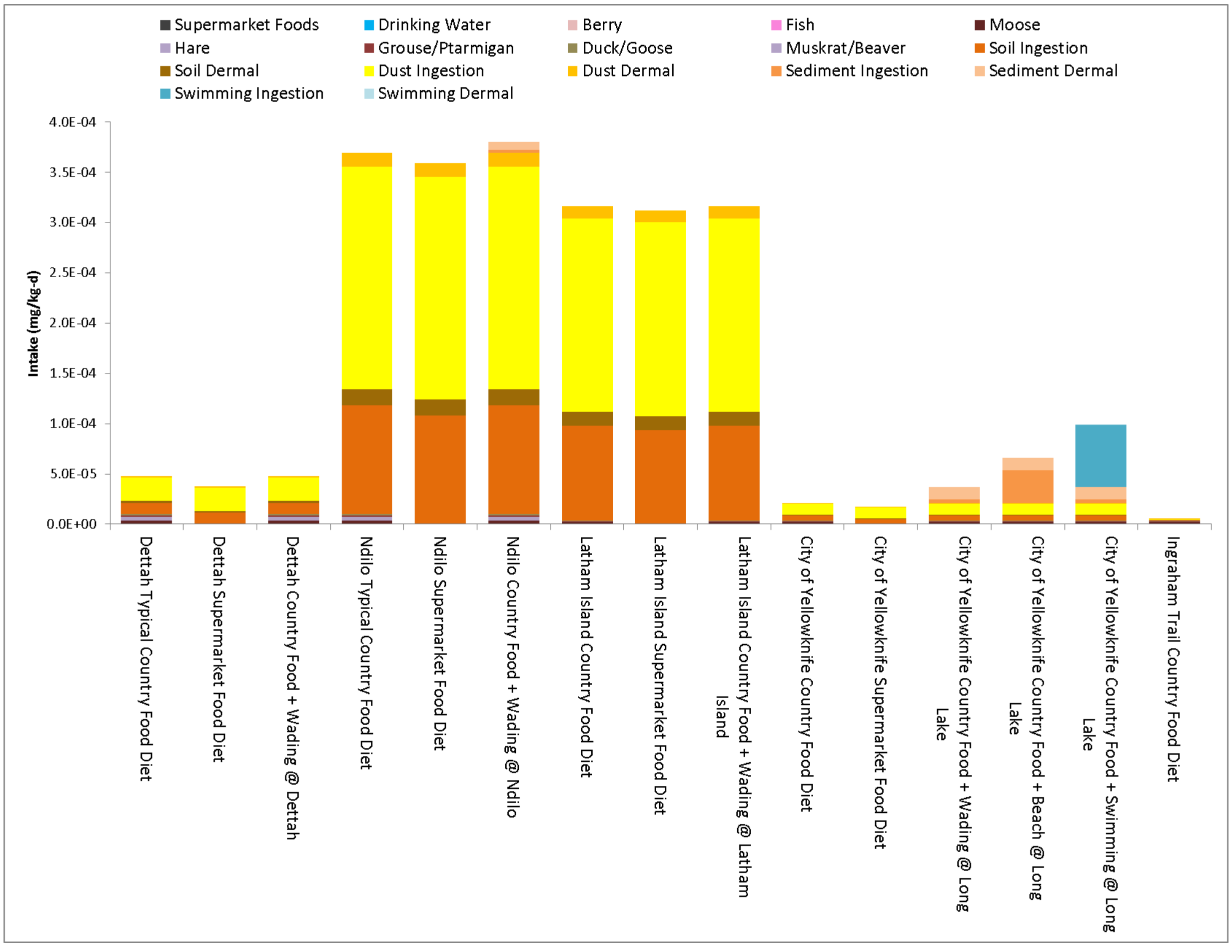


Figure F.29 shows that, after supermarket foods, toddlers are most exposed to antimony in fish. For some locations, antimony in soil and indoor dust contributes to the total exposure via the ingestion and skin contact pathways. Estimated intakes for all life stages and scenarios are provided in Table F.43.

Figure F.29 Estimated intakes for toddler – antimony

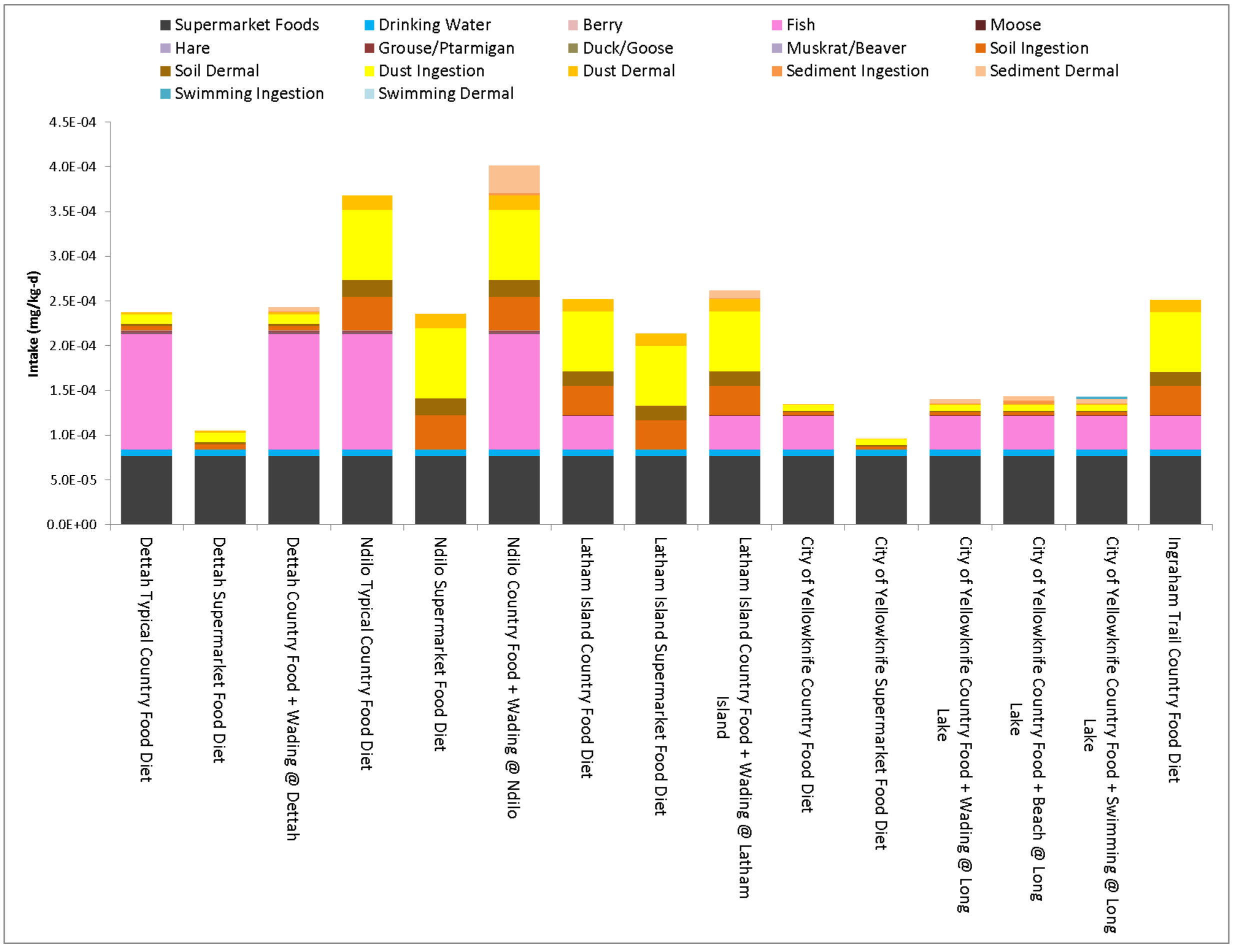

Figure F.30 shows that supermarket foods contribute almost completely to the total intake of manganese for toddlers. Other pathways such as drinking water, air, country foods, soil, and indoor dust are essentially negligible compared with supermarket food intakes. Estimated intakes for all life stages and scenarios are provided in Table F.44.

Figure F.30 Estimated intakes for toddler – manganese

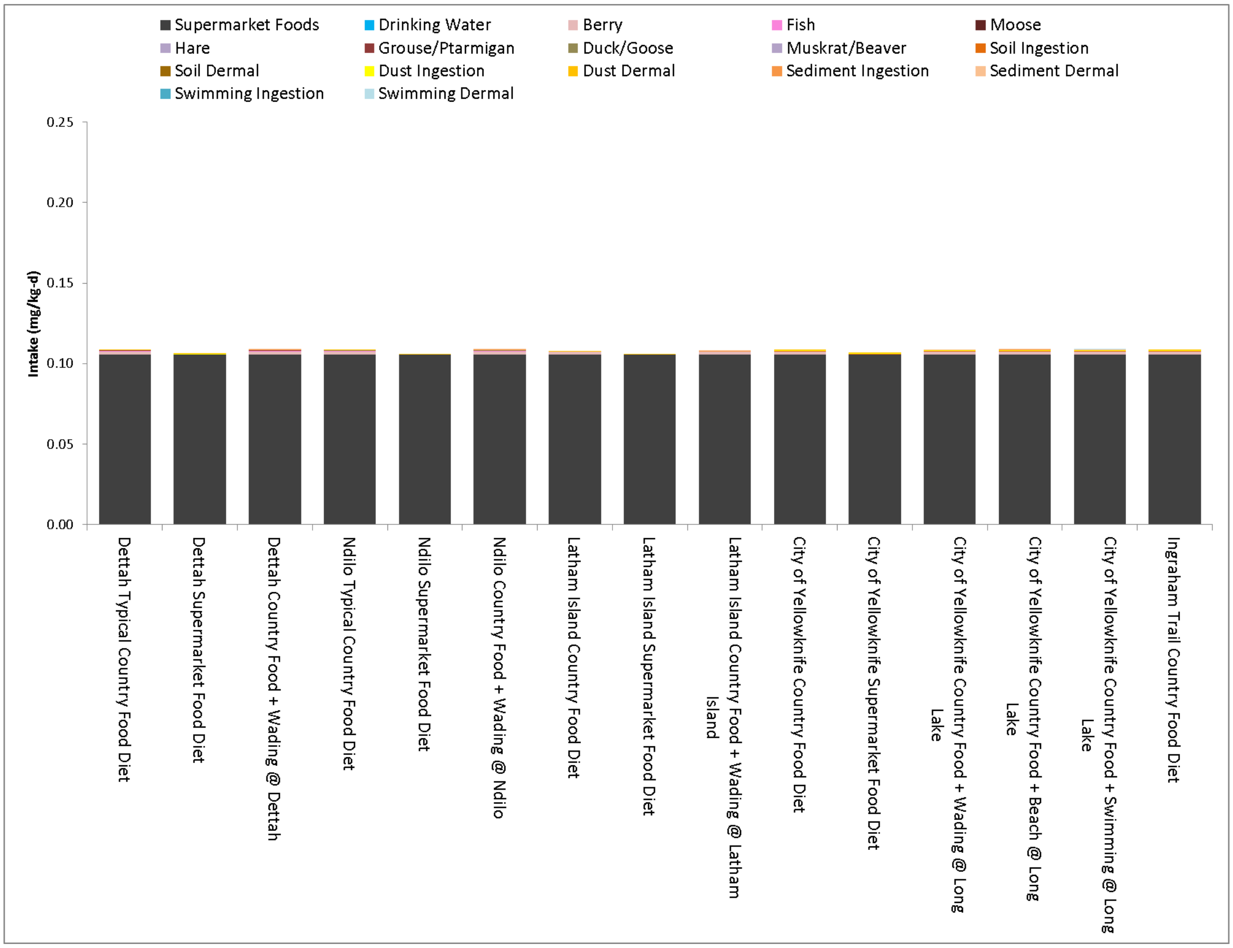

Figure F.31 shows estimated intakes associated with background exposures for the five life stages considered in the HHRA for total arsenic, antimony, and manganese. Intakes for total arsenic from background are dominated by the intake of arsenic in fish and supermarket foods, and, to a lesser extent, drinking water. Background exposures to antimony are similarly dominated by intakes from fish and supermarket foods, and, to a lesser extent, muskrat/beaver. Background exposures to manganese are dominated by the intake of manganese in supermarket foods. Estimated intakes for all life stages and scenarios are provided in Table F.46.

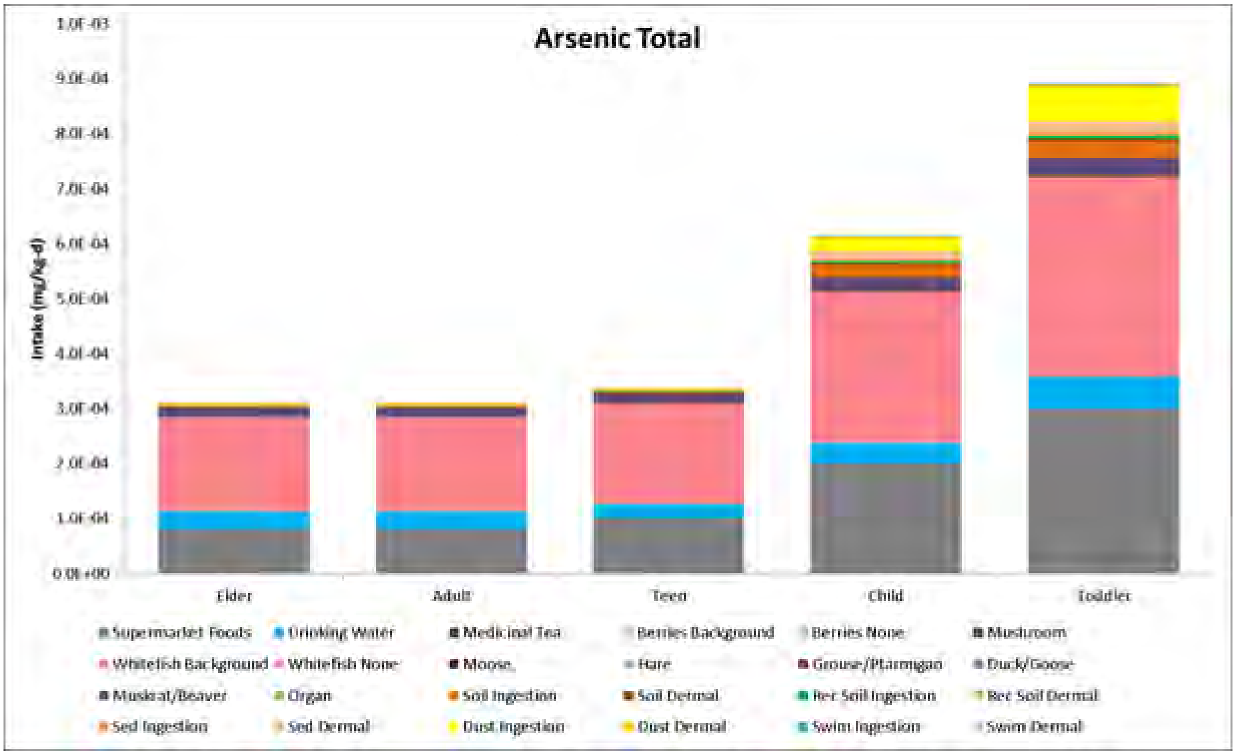
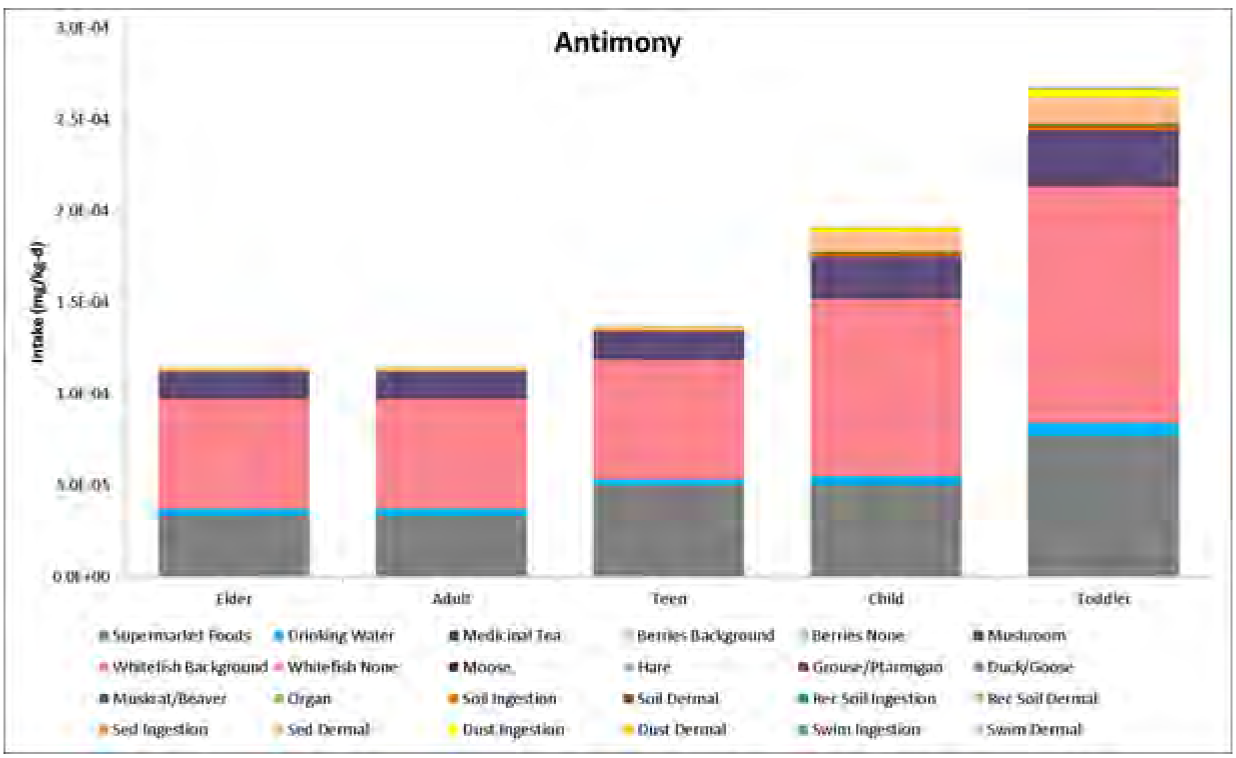
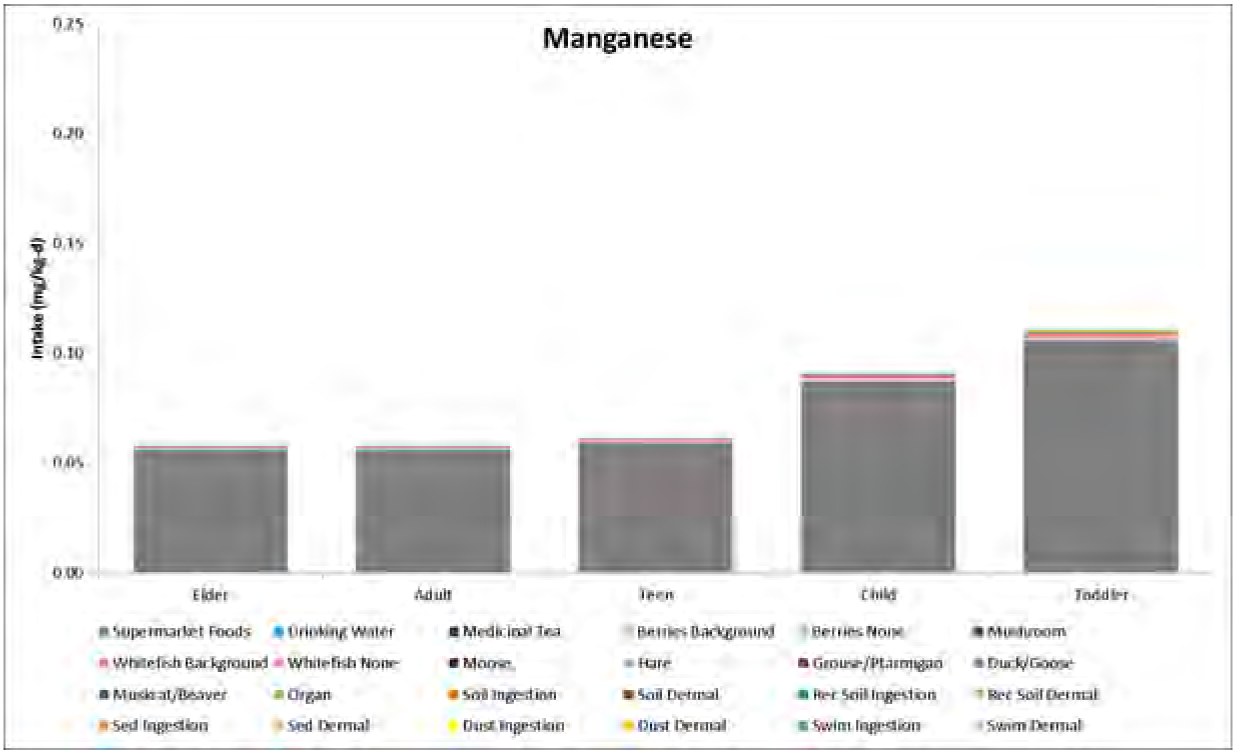
Figure F.31 Estimated intakes for background







Background exposures are, in some cases, underestimated due to a lack of available data. Background air concentrations for antimony and manganese were assumed to be zero in the absence of other information. Similarly, there were no data to determine the background concentrations of antimony and manganese in hare flesh, moose organs, or grouse organs.

As mentioned, estimated intakes for all life stages and scenarios are provided in Table F.42, Table F.43, and Table F.44 for arsenic, antimony, and manganese, respectively. Intakes associated with background exposures are provided in Table F.46. Exposures via the inhalation pathway are not assessed as intakes, but rather in comparison to reference concentrations associated with toxicological effects. Therefore, the inhalation pathway is not included in the tables. The sample calculations provided in Appendix I illustrate that the inhalation pathway is insignificant in the current assessment.

Table F.42 Estimated intakes by pathway – total arsenic

F.8 Sample Calculation

An example sample calculation for Ndilo Typical Country Food Diet scenario exposure for adult is provided in the following steps. Sample calculations for all lifestages, pathways, COPC, locations, and scenarios are provided in Appendix I. As discussed previously, the same equation (Equation F-3) was used to estimate exposure from ingestion of all foods (i.e., berry, medicinal tea, mushroom, fish, moose, hare, grouse, duck, and muskrat) and therefore sample calculations for each food item are not shown here. Similarly, Equation F-4 was used to estimate exposure from ingestion of dust, soil, and sediment, while Equation F-1 was used to estimate exposure from dermal contact with dust, soil, sediment, and water. Thus, only a few of these pathways are shown below.

Exposure via drinking water (Equation F-2) – antimony:

$$Intake - water = \frac{0.0002\frac{mg}{L} \times 1.5\ \frac{L}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg} = 4.2 \times 10^{-6}\frac{mg}{kg\ d}$$

Exposure via fish ingestion (Equation F-3) – antimony:

$$Intake - fish\ (A2) = \frac{0.025\frac{mg}{kg\ ww} \times 0.17\ \frac{kg\ ww}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg} \times 10\%$$

$$= 6.0 \times 10^{-6}\frac{mg}{kg\ d}$$

$$Intake - fish\ (A3) = \frac{0.025\frac{mg}{kg\ ww} \times 0.17\ \frac{kg\ ww}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg} \times 90\%$$

$$= 5.4 \times 10^{-5}\frac{mg}{kg\ d}$$

$$Intake - fish\ (total) = 6.0 \times 10^{-6}\frac{mg}{kg\ d} + 5.4 \times 10^{-5}\frac{mg}{kg\ d} = 6.0 \times 10^{-5}\frac{mg}{kg\ d}$$

Exposure via moose ingestion (Equation F-3) – antimony:

$$Intake - moose = \frac{0.0018\,\frac{mg}{kg\ ww} \times 0.0069\ \frac{kg\ ww}{d} \times 7\,\frac{d}{wk} \times 52\,\frac{wk}{yr}}{7\,\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg}$$
$$= 1.8 \times 10^{-7}\,\frac{mg}{kg\ d}$$

Exposure via soil ingestion (Equation F-4) – antimony:

$$Intake - soil = \frac{45\,\frac{mg}{kg\ dw} \times 1.6 \times 10^{-6}\ \frac{kg\ dw}{d} \times 7\,\frac{d}{wk} \times 16\,\frac{wk}{yr}}{7\,\frac{d}{wk} \times 16\ \frac{wk}{yr} \times 70.7kg} = 1.0 \times 10^{-6}\,\frac{mg}{kg\ d}$$

Total exposure via ingestion – antimony:

$$\begin{aligned} &Total\ Intake - ingestion \\ &= Intake - water\left(4.2 \times 10^{-6}\,\frac{mg}{kg\ d}\right) + Intake \\ &- fish\left(6.0 \times 10^{-5}\,\frac{mg}{kg\ d}\right) + Intake - moose\left(1.8 \times 10^{-7}\,\frac{mg}{kg\ d}\right) \\ &+ Intake - berry\ \left(3.3 \times 10^{-8}\,\frac{mg}{kg\ d}\right) + Intake \\ &- hare\left(5.5 \times 10^{-7}\,\frac{mg}{kg\ d}\right) + Intake - grouse\left(5.9 \times 10^{-7}\,\frac{mg}{kg\ d}\right) \\ &+ Intake - duck\left(1.2 \times 10^{-7}\,\frac{mg}{kg\ d}\right) + Intake \\ &- muskrat\left(2.7 \times 10^{-7}\,\frac{mg}{kg\ d}\right) + Intake - soil\left(1.0 \times 10^{-6}\,\frac{mg}{kg\ d}\right) \\ &+ Intake - dust\left(1.1 \times 10^{-7}\,\frac{mg}{kg\ d}\right) + Intake \\ &- supermarket\left(3.3 \times 10^{-5}\,\frac{mg}{kg\ d}\right) = 1.0 \times 10^{-4}\,\frac{mg}{kg\ d} \end{aligned}$$

Exposure via soil dermal contact (Equation F-1) – antimony:

$$Dermal - soil = \frac{45\frac{mg}{kg\ dw} \times 1.7 \times 10^{-4}\ \frac{kg\ dw}{d} \times 7\frac{d}{wk} \times 16\frac{wk}{yr}}{7\frac{d}{wk} \times 16\ \frac{wk}{yr} \times 70.7kg} \times 0.1$$

$$= 1.1 \times 10^{-5}\frac{mg}{kg\ d}$$

Total exposure via dermal contact – antimony:

$$Total\ Dermal = Dermal - soil\left(1.1 \times 10^{-5}\frac{mg}{kg\ d}\right) + Dermal - dust\left(7.9 \times 10^{-6}\frac{mg}{kg\ d}\right) = 1.9 \times 10^{-5}\frac{mg}{kg\ d}$$

Incremental exposure via drinking water (Equation F-2) – arsenic:

$$Incremental\ Intake - water = \frac{(0.0016 - 0.0016)\frac{mg}{L} \times 1.5\ \frac{L}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg}$$

$$= 0\frac{mg}{kg\ d}$$

Incremental exposure via fish (Equation F-3) – arsenic:

$$Incremental\ Intake - fish\ (A2) = \frac{(0.063 - 0.07)\frac{mg}{kg\ ww} \times 0.17\ \frac{kg\ ww}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg} \times 10\%$$

$$= 0\frac{mg}{kg\ d}$$

$$Incremental\ Intake - fish\ (A3) = \frac{(0.054 - 0.07)\frac{mg}{kg\ ww} \times 0.17\ \frac{kg\ ww}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg} \times 90\%$$

$$= 0\frac{mg}{kg\ d}$$

$$Incremental\ Intake - fish\ (total) = 0\ \frac{mg}{kg\ d} + 0\ \frac{mg}{kg\ d} = 0\ \frac{mg}{kg\ d}$$

Incremental exposure via moose ingestion (Equation F-3) – arsenic:

$$Incremental\ Intake - moose = \frac{(0.020 - 0.006)\frac{mg}{kg\ ww} \times 0.0069\ \frac{kg\ ww}{d} \times 7\frac{d}{wk} \times 52\frac{wk}{yr}}{7\frac{d}{wk} \times 52\ \frac{wk}{yr} \times 70.7kg} = 2.9 \times 10^{-6}\frac{mg}{kg\ d}$$

Incremental exposure via soil ingestion (Equation F-4)– arsenic:

$$Incremental\ Intake - soil = \frac{(163 - 35.7)\frac{mg}{kg\ dw} \times 1.6 \times 10^{-6}\ \frac{kg\ dw}{d} \times 7\frac{d}{wk} \times 16\frac{wk}{yr}}{7\frac{d}{wk} \times 16\ \frac{wk}{yr} \times 70.7kg} = 2.9 \times 10^{-6}\frac{mg}{kg\ d}$$

Total incremental exposure via ingestion – arsenic:

$$Total\ Incremental\ Intake - ingestion = Incremental\ Intake - water\left(0\frac{mg}{kg\ d}\right) + Incremental\ Intake - fish\left(0\frac{mg}{kg\ d}\right) + Incremental\ Intake - moose\left(2.9\times10^{-6}\frac{mg}{kg\ d}\right) + Incremental\ Intake - berry\left(4.5\times10^{-7}\frac{mg}{kg\ d}\right) + Incremental\ Intake - hare\left(1.6\times10^{-6}\frac{mg}{kg\ d}\right) + Incremental\ Intake - grouse\left(7.3\times10^{-7}\frac{mg}{kg\ d}\right) + Incremental\ Intake - duck\left(7.1\times10^{-7}\frac{mg}{kg\ d}\right) + Incremental\ Intake - muskrat\left(0\frac{mg}{kg\ d}\right) + Incremental\ Intake - soil\left(2.9\times10^{-6}\frac{mg}{kg\ d}\right) + Incremental\ Intake - dust\left(3.2\times10^{-6}\frac{mg}{kg\ d}\right) + Incremental\ Intake - supermarket\left(0\frac{mg}{kg\ d}\right) = 1.1\times10^{-5}\frac{mg}{kg\ d}$$

Incremental exposure via soil dermal contact (Equation F-1) – arsenic:

$$Incremental\ Dermal - soil = \frac{(163-35.7)\frac{mg}{kg\ dw}\times1.7\times10^{-4}\ \frac{kg\ dw}{d}\times7\frac{d}{wk}\times16\frac{wk}{yr}}{7\frac{d}{wk}\times16\ \frac{wk}{yr}\times70.7kg}\times0.03 = 9.3\times10^{-6}\frac{mg}{kg\ d}$$

Total incremental exposure via dermal – arsenic:

$$Total\ Incremental\ Dermal = Incremental\ Dermal - soil\left(9.3\times10^{-6}\frac{mg}{kg\ d}\right) + Incremental\ Dermal - dust\left(6.7\times10^{-6}\frac{mg}{kg\ d}\right) = 1.6\times10^{-5}\frac{mg}{kg\ d}$$

APPENDIX G

HUMAN HEALTH TOXICITY REVIEW

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX G: HUMAN HEALTH TOXICITY REVIEW

In terms of human health, toxicity is the potential for a chemical to cause some type of damage, either permanent or temporary, to the structure or functioning of any part of the body. The toxicity depends on the amount of the chemical taken into the body (generally termed the intake or dose) and the length of time a person is exposed. Every chemical has a specific dose and duration of exposure that is required to produce a toxic effect in humans. Toxicity assessments generally involve the evaluation of scientific studies, generally based either on laboratory animal tests or on workplace exposure investigations, by a number of experienced scientists in a wide range of scientific disciplines in order to determine the maximum dose that a human can be exposed to without having an adverse health effect; these values are adopted as the Toxicity Reference Value (TRV). These TRVs consider the most sensitive toxicological endpoints in individuals and adjust for them with uncertainty factors.

The TRVs for humans are intended to protect the most sensitive individuals (i.e., the elderly, pregnant women, and children) as well as people with compromised health such as asthmatics. For constituents of potential concern (COPC) that have non-carcinogenic effects, the TRVs are based on threshold effects concentrations. Typically, exposures below these TRVs would not be associated with adverse health effects and, thus, would not represent a concern. As exposures increase to levels above the TRV, the probability of increased health risk increases. However, exposures above the TRV do not necessarily mean that adverse health risks occur. For COPC that have carcinogenic effects (i.e., those COPC that can cause cancer), the TRVs are based on non-threshold effects.

For dermal exposure, TRVs are not generally available. Therefore, dermal exposures are generally added to the ingestion exposures once adjustments are made to account for differences in absorption (see Appendix F).

The COPC considered for the Human Health Risk Assessment (HHRA) are arsenic, antimony, and manganese.

Antimony and manganese are considered to be non-classifiable with respect to human carcinogenicity (with respect to the oral exposure route), meaning that there are insufficient human or animal data to indicate that they are carcinogens. Arsenic, however, is considered to have both carcinogenic and non-carcinogenic endpoints.

Table G.1 provides a summary of the TRVs selected for use in the HHRA for oral exposure. The TRVs were all obtained from Health Canada (2010) or the United States Environmental Protection Agency (U.S. EPA) Integrated Risk Information System (IRIS) database (U.S. EPA 2017). The TRVs, health effects (toxicological endpoints), and reference sources for each TRV are provided in the table. The following sections provide a brief discussion of the toxicity of the three selected COPC.

Table G.1 Summary of toxicity reference values for humans

COPC	Oral Toxicological Reference Value					Inhalation Toxicological Reference Value				
	Carcinogenic (mg/(kg-d))$^{-1}$		Non-Carcinogenic (mg/(kg-d))		Endpoint	Carcinogenic (mg/m^3)$^{-1}$		Non-Carcinogenic (mg/m^3)		Endpoint
Antimony	N/A		4.0x10^{-4}	U.S. EPA (2017; last updated 1991)	Longevity, blood glucose and cholesterol	N/A		N/A	N/A	–
Arsenic	1.8	Health Canada (2010)	N/A		Internal cancers	6.4	Health Canada (2010)	N/A		Lung cancer
Manganese	N/A		0.136 (toddler) 0.122 (child) 0.142 (teen) 0.156 (adult)	Health Canada (2010)	Neurotoxicity	N/A		5.0x10^{-5}	U.S. EPA (2017; last updated 1996)	Impairment of Neuro-behavioural function

N/A – Not applicable.
For antimony, the only inhalation TRV available is for antimony trioxide which is not considered the appropriate form of antimony in air in Yellowknife.
There are no TRVs for dermal exposures; dermal exposures are added to oral exposures after adjustments are made for absorption.

G.1 Arsenic

In its elemental form, arsenic (As) is a steel gray metal-like substance that is found naturally in the earth's crust. Arsenic has four oxidation states, (-3, arsine), (0, metal), (+3, arsenite), and (+5, arsenate), although it is usually found as inorganic arsenic sulphide or as metal arsenates and arsenides. Organic arsenic compounds can also form, but are typically less toxic than inorganic arsenic compounds.

Exposure pathways for arsenic typically include air, water, food and soil via inhalation and ingestion as well as dermal contact. Each exposure pathway can involve exposure to different forms of arsenicals with different bioavailabilities. For example, inorganic arsenic in drinking water is more bioavailable than organic arsenic in fish.

The absorption of arsenic compounds via oral exposure is largely dependent on its solubility in water, while the absorption of arsenic compounds via inhalation is dependent both on solubility and particle size. Dermal absorption of arsenic compounds is not well characterized, but it is thought to be lot less significant than other exposure routes.

G.1.1 Metabolism

Inorganic arsenic metabolism is quite complex and leads to the formation of various arsenic species that are very different in toxicity, tissue distribution, and rate of elimination. Inorganic arsenic, in both the trivalent and pentavalent oxidation states, can easily be absorbed within the gastrointestinal tract. In low-to-moderate exposure situations, absorbed pentavalent arsenic is largely reduced to trivalent arsenic in the blood (Vahter 2002). Hepatocytes mainly absorb trivalent arsenic (Lerman et al. 1983) and metabolize it to monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA), both of which may exist in the trivalent and pentavalent oxidation states. In order to carry out these transformations, the enzyme arsenic methyl transferase (AS3MT) is needed and S-adenosyl methionine serves as the methyl donor (Lin et al. 2002). Thus, human tissues, blood, and urine contain a mixture of arsenic metabolites that vary in toxicity.

Cell and animal-model systems provide evidence that the trivalent species of inorganic arsenic, MMA, and DMA are far more toxic than the less reactive pentavalent species. For example, MMA(III) has been shown to be particularly cytotoxic in human cell cultures (Styblo et al. 2000). It is unclear as to the extent to which DMA(V) can be reduced to the more toxic DMA(III); however, there is some evidence that DMA(III) is also found in human biologic samples (Valenzuela et al. 2005). Thus, the retention of arsenic in tissues is influenced by a host of factors, particularly methylation capacity. Tissues vary extensively in their arsenic methylation efficiency (Kobayashi et al. 2007), which probably affects their susceptibility to arsenic toxicity.

The ability to metabolize inorganic arsenic varies widely in humans, as shown by the widely varying proportions of inorganic arsenic, MMA, and DMA in urine and blood. It seems that women are more efficient than men in converting inorganic arsenic to DMA, particularly during pregnancy, when arsenic metabolism is enabled (Vahter et al. 2006). Also, children appear to methylate arsenic similar to adults (Wasserman et al. 2004). There is evidence from epidemiologic studies in populations exposed to high arsenic concentrations in drinking water in Taiwan, Argentina, and Bangladesh that shows that individuals who can efficiently convert inorganic arsenic to DMA are at lower risk for arsenic-induced disease than those who cannot convert arsenic as efficiently.

The form of arsenic impacts on the rate at which arsenic is excreted from the body. Some of the inorganic arsenic is mainly excreted via urine as the form of arsenic ingested. After methylation, it is also excreted as MMA and DMA. Between 50 to 90% of blood arsenic is cleared from the body in two to four days (NRC 1977). The remainder is cleared 10 to 100 times more slowly.

G.1.2 Toxic Forms of Arsenic

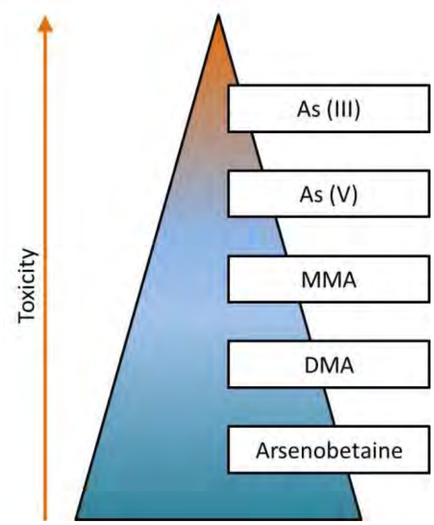
Trivalent arsenic (As^{3+}) is generally more toxic than pentavalent arsenic (As^{5+}) due to its affinity for sulfhydryl groups of biomolecules (e.g., thiol groups in enzymes). Pentavalent arsenic toxicity results from its interference with oxidative phosphorylation in cells by substituting for P (phosphate) in adenosine triphosphate (ATP) synthesis, which results in a deactivation of intracellular energy storage (Jang et al. 2016). The problem with arsenic toxicity is the formation of by-products of oxidation of arsenate, which are arsenite, MMA, and DMA, which does not allow for a clear dose-response curve. While the methylation of arsenate helps in the removal of arsenic from the body, it has been shown to increase the levels of these three toxicants.

Research has shown that all four forms of arsenic (As^{3+}, As^{5+}, DMA, MMA) have adverse effects at the cell metabolism level by damaging cell DNA or by reacting with critical sulfhydryl containing enzymes; however, it is unclear how to correlate data obtained from animal studies to actual human effects (Hughes et al. 2011). Arsenic and its metabolites are believed to have adverse influences at the cell level.

Organic arsenic compounds, such as arsenobetaine, are found in fish and shellfish. This form of arsenic is generally assumed to be the least toxic of the arsenic species (Department for Environment, Food and Rural Affairs & the Environment Agency [DEFRA/EA 2002]).

Figure G.1 shows a schematic of the relative toxicities of the arsenic species. Due to the fact that there are no definitive dose response curves for the various arsenic species As^{3+}, As^{5+}, DMA, MMA, they have all been assumed to have the same toxicity as As^{3+}. Arsenobetaine has been assumed to be non-toxic.

Figure G.1 Schematic of the relative toxicities of arsenic species



G.1.3 Toxicity Endpoints

Inorganic arsenic and its metabolites have many targets of toxicity and carcinogenicity. The International Agency for Research on Cancer (IARC 2012) lists the lung, urinary bladder, and skin as known targets for arsenic toxicity and the prostate, liver, and kidney as three probable targets for carcinogenicity. The Agency for Toxic Substances and Disease Registry (ATSDR 2016) provides a detailed discussion of the various toxicity endpoints for arsenic. The focus of this discussion is on the known targets for arsenic toxicity, as these are the endpoints used in the derivation of the TRVs by both Health Canada and the U.S. EPA.

As discussed above, the literature suggests that there is evidence of sex differences in the metabolism and toxicity of arsenic. However, the current available TRVs have not included these differences. The U.S. EPA is considering sex differences related to bladder and lung cancer in their updated document on arsenic toxicity.

Skin Effects

There is a well-established dose-response relationship with skin lesions and arsenic in drinking water. The ATSDR (2007) based its chronic minimal risk level of 0.0003 mg/kg-d on skin lesions. Skin lesions have been noted to occur at concentrations as low as 10 µg/L in cross-sectional (Ahsan et al. 2006) and prospective cohort (Argos et al. 2011) studies from exposure in Bangladesh.

In a Mexican cross-sectional study of people living near mining operations consuming contaminated groundwater found that residents with skin lesions had urinary MMA concentrations of 7.5 µg/L, whereas residents who did not have skin lesions had 4.8 µg/L MMA in their urine (Valenzuela et al. 2005). Kile et al. (2011) also shown that urinary MMA concentration is associated with an increased risk of skin lesions in a case-control study.

Arsenic is a known skin carcinogen, first classified by the IARC in 1987 on the basis of observations of patients treated with the arsenical Fowler's solution. A causal relationship between arsenic in drinking water and skin cancer was verified by IARC in a 2012 publication based on ecologic studies in Taiwan, primarily in the southwest region, where geologic arsenic is endemic (Wu et al. 1989). Most published studies linking arsenic exposure to skin cancer have found supportive evidence of non-melanoma skin cancers (basal-cell and squamous-cell carcinoma).

Respiratory Effects

Arsenic exposure via drinking water has also been linked to lung cancer in humans. Associations have been observed in highly exposed populations in Taiwan, Japan, Chile, Argentina, and the United States (Guo 2004; IARC 2004, 2012).

Arsenic's non carcinogenic pulmonary effects have been less well studied than its lung-cancer effects, but results of a number of human epidemiologic studies suggest deleterious effects of arsenic on a variety of nonmalignant pulmonary outcomes, including respiratory symptoms, airway epithelial damage, impaired pulmonary function, chronic obstructive pulmonary disease (COPD), and tuberculosis (Mazumder et al. 2000, 2005; Milton and Rahman 2002; Milton et al. 2003; Parvez et al. 2008; Rahman et al. 2011; Smith et al. 2011).

Bladder Effects

Arsenic is also known to cause bladder cancer (IARC 2004, 2012) based on ecologic studies of highly exposed populations in Taiwan, Chile, and Argentina. These studies indicated higher mortality from bladder cancers in exposed populations than in non-exposed populations. A case-control study in Chile (Steinmaus et al. 2013) found evidence of a dose-related increase in bladder-cancer incidence, which establishes a causal relationship between arsenic exposure and bladder cancer.

G.1.4 Toxicity Reference Values – Inorganic Arsenic

The U.S. EPA published a toxicological summary of inorganic arsenic in 1988 and started to update the assessment in 2003. In 2005, IRIS released a draft arsenic assessment related to the carcinogenic effects of oral exposure to inorganic arsenic for public comment and review by the U.S. EPA's Science Advisory Board (SAB). The SAB provided recommendations in 2007, and in 2010 the U.S. EPA released a revised draft inorganic arsenic assessment focusing on carcinogenic effects. In 2011, the SAB provided comments and the U.S. EPA is currently working to develop an updated IRIS assessment focused on both cancer and non-cancer effects. Therefore, the current TRVs available in the IRIS database (U.S. EPA 2017) are still being used in risk assessments. As chronic exposure is being examined, this discussion will focus on the carcinogenic TRVs for arsenic.

The IRIS database (U.S. EPA 2017; last updated 1998) provides an oral slope factor of 1.5 $(mg/kg\text{-}d)^{-1}$ for skin cancer based on a cross-sectional study of Taiwanese people exposed to drinking water (Tseng et al. 1968a; Tseng 1977).

An oral slope factor of 2.8 $(mg/kg\text{-}d)^{-1}$ has previously been derived by Health Canada (2004) based on the incidence of skin cancers in the epidemiological studies by Tseng et al. (Tseng et al. 1968b) and Tseng (Tseng 1977). In 2010, Health Canada considered new data that have become available that suggest that the risk of internal cancers due to ingestion of drinking water is greater than previously believed. The cancer risk models based on the Taiwanese data have been updated (Morales et al. 2000), and an evaluation was completed by Health Canada of the cancer potency indices for liver, lung ,and bladder cancers. An oral slope factor of 1.8 $(mg/kg\text{-}d)^{-1}$ was derived (Health Canada 2010) and is used in this assessment. The risk specific dose associated with a "negligible" risk of 1 x 10^{-5} is 0.0056 µg/kg-d.

Health Canada has previously suggested that the approach of the Joint FAO/WHO Expert Committee on food Additives (JECFA) and the European Food Safety Authority (EFSA) be considered for risk assessments for the Giant Mine. JECFA (2011) derived a low-end Benchmark Dose Level ($BMDL_{0.5}$) for a 0.5% increased incidence of lung cancer using a range of assumptions to estimate exposure from drinking water and food with differing concentrations of arsenic. The $BMDL_{0.5}$ was determined to be 3 µg/kg d (range of 2 to 7 µg/kg-d based on the range of estimated dietary exposure). For a "negligible" risk value of 1 x 10^{-5}, the risk specific dose is determined to be 0.006 µg/kg d based on linear extrapolation. This risk specific dose is similar to the one determined by using the Health Canada (2010) slope factor of 1.8 $(mg/kg\text{-}d)^{-1}$. Therefore the use of the $BMDL_{0.5}$ or the cancer slope factor would give the same overall results with respect to estimates of the incremental cancer risk for the community in and around Yellowknife.

Table G.2 provides a summary of the oral carcinogenic endpoints.

Table G.2 Carcinogenic oral exposure limits for arsenic

TRV $(mg/kg\text{-}d)^{-1}$	Basis	Effects	Source
1.8	-Poisson model fit (Morales et al. 2000). -Based on upper range of mean unit risks. -Exposure from drinking water.	Liver, lung and bladder cancers	Health Canada (2010)
1.5	-Time-and-dose-related formulation of the multistage model. -Exposure from drinking water (Tseng et al. 1968b; Tseng 1977).	Skin cancer in humans	U.S. EPA (2017; last updated 1998)
2.8	-Based on tumourigenic dose, TD_{05} (total intake that corresponds to 5% increase in incidence or mortality due to tumours associated with exposure). -TD_{05} of 0.018 mg/kg-d, derived from TC_{05} of 840 µg/L (Health Canada 1996) using a body weight of 70.7 kg and water ingestion rate of 1.5L/d -$SF_o = 0.05/TD_{05}$.	Skin cancer in humans	Health Canada (2004)

Health Canada (2010) provides an inhalation unit risk of 6.4 $(mg/m^3)^{-1}$. This was derived by Environment Canada/Health Canada (EC/HC 1993) in which three different TD_{05} values were presented (7.83 µg/m^3, 10.2 µg/m^3, and 50.5 µg/m^3) based on three occupational studies of smelter workers at the Tacoma, Anaconda, and Ronnskar smelters. The unit risk was obtained by dividing the most conservative value of 7.83 µg/m^3 into 0.05 (Health Canada 1996).

The IRIS database (U.S. EPA 2017; last updated 1998) provides an inhalation unit risk of 4.3 $(mg/m^3)^{-1}$. This is based on occupational studies of male workers at the Anaconda smelter in Montana and at the Tacoma ASARCO smelter in Washington who showed an increased risk of developing lung cancer following inhalation exposure to arsenic. The extrapolation method used to generate the slope factor was the absolute-risk linear model, and a geometric mean of the different unit risks from each study was used to derive the unit risk.

The California Environmental Protection Agency (CalEPA 2009) derived an inhalation unit risk of 3.3 $(mg/m^3)^{-1}$ for lung tumour incidence using a relative risk model adjusted for interaction with tobacco smoking on data from a human occupational exposure study by Enterline et al. (1987). (CDHS 1990)

The World Health Organization (WHO 2000) provide a unit risk of 1.5 $(mg/m^3)^{-1}$, derived from an estimated cancer risk of 1.5 x 10^{-3} for lifetime exposure to arsenic at a concentration of 1 $\mu g/m^3$ in air. The value was estimated by pooling risk estimates from studies conducted on workers at various smelters (Viren and Silvers 1994).

Table G.3 provides a summary of the carcinogenic inhalation exposure limits for arsenic.

Table G.3 Carcinogenic inhalation exposure limits for arsenic

TRV $(mg/m^3)^{-1}$	Basis	Effects	Source
6.4	-Based on tumourigenic concentration, TC_{05} (concentration that corresponds to 5% increase in incidence or mortality due to tumours associated with exposure). -TC_{05} of 0.0078 mg/m^3 (EC/HC 1993; Health Canada 1996). -$UR_i = 0.05/TC_{05.}$	Lung cancer	Health Canada (2010)
4.3	-occupational inhalation exposure (Brown and Chu 1983a, 1983b, 1982; Lee-Feldstein 1983; Higgins 1982; Enterline and Marsh 1982). -Geometric mean of geometric means from two datasets.	Lung cancer	U.S. EPA (2017; last updated 1998)
3.3	-Human occupational exposure study (Enterline and Marsh 1982); relative risk model, adjusted for interaction with tobacco smoking (CDHS 1990).	Lung tumor incidence	CalEPA (2009)
1.5	-Cancer risk of 1.5 x 10^{-3} for lifetime exposure to concentration of 1 $\mu g/m^3$ (URi=risk/concentration). -Estimated by pooling risk estimates from studies on various smelters (Viren and Silvers 1994).	Lung cancer	WHO (2000)

G.2 Antimony

Antimony toxicity occurs either due to occupational exposure or during therapy. Occupational exposure may cause respiratory irritation, pneumoconiosis, antimony spots on the skin and gastrointestinal symptoms. Antimony has not been designated as a potentially carcinogenic compound. The critical effect endpoint for antimony include effects on longevity, blood glucose, and cholesterol levels. In a chronic study conducted on rats fed potassium antimony tartrate in water, effects, including decreased longevity, decreased blood glucose levels, and altered cholesterol levels, were observed in the test organisms (U.S. EPA 2017).

G.2.1 Pharmacokinetics

There is no available quantitative information on absorption of antimony through the respiratory tract following inhalation exposure in humans or animals. Cooper et al. (1968) and Ludersdorf et al. (1987) showed increased levels of antimony in the urine and blood of workers exposed to antimony via inhalation, although absorption could have taken place through the gastrointestinal (GI) tract due to mucociliary clearance following inhalation.

There is little available information on absorption of antimony through the GI tract following oral exposure, but the few animal studies that were conducted suggest GI tract absorption ranges from 1.6% to 15% and is dependent on the chemical form and solubility of the antimonial (Health Canada 1997). There is no data available on the gut absorption of antimony in humans. The International Commission on Radiation Protection (ICRP 1981) recommends the following GI absorption values for antimony: 10% for antimony tartrate and 1% for all other antimony forms.

There are few data available on the distribution of antimony in humans following absorption. Human data on the absorption of the anti-parasitic agent trivalent antimony show higher accumulation in the liver, the thyroid, and the heart (Abdalla and Saif 1962).

G.2.2 Toxicity Endpoints

Antimonials used as anti-parasitic agents in humans are known to have side effects that include myocarditis, hepatitis, and nephritis (U.S. EPA 1980). Symptoms of acute oral and inhalation exposures to antimony include GI disorders, dehydration, muscular pain, shock, and kidney and urinary disorders. Dermal exposure to antimonials in humans can result in eczema and dermatitis (Stemmer 1976).

Subchronic oral and subcutaneous animal exposures to antimonials have resulted in liver, kidney, and GI disorders (Levina and Chekunova 1965; Fleming 1982). Subchronic inhalation exposures in animals to antimony dusts resulted in heart complications and electrocardiac disorders (Brieger et al. 1954). Subchronic oral animal exposures to antimonials in the diet showed reduced growth, appetite, and body weight gain and alterations in hematologic parameters (Health Canada 1997). Subchronic oral exposures to antimonials in water given to rats resulted in changes to the thymus, liver, kidneys, pituitary glands and spleen (Poon et al. 1998). Chronic rodent exposures to antimonials in drinking water resulted in weight loss, decreased weight gain, shortened life span, and reduced longevity (Schroeder et al. 1968, 1970; Kanisawa and Schroeder 1969).

Chronic occupational exposure to antimonials at low doses has been shown to result in myocardial effects, which can include heart complications, electrocardiac disorders, and sudden death (Brieger et al. 1954). Occupational exposures to antimonials have also been shown to cause reproductive effects in women, including increases in menstrual disorders and spontaneous abortions and development effects in offspring, including low birth weight (Beliaeva 1967). Acute and subchronic rat studies suggest that inhalation and intraperitoneal prenatal exposures to antimonials can decrease reproductive success and that oral exposure via drinking water can result in body weight decreases in pregnant dams and developing pups (Health Canada 1997).

G.2.3 Toxicity Reference Values

Health Canada (2010) has no published TRVs for antimony. Health Canada (1997) provide an oral tolerable daily intake of 0.0002 mg/kg-d derived from a NOAEL of 0.06 mg/kg-d from a 13-week rat study involving oral administration of potassium antimony tartrate at concentrations equivalent to 0 mg/L, 0.5 mg/L, 5.0 mg/L, 50 mg/L, and 500 mg/L via drinking water (Poon et al. 1998). The authors identified a NOAEC of 0.5 mg/L antimony which corresponded to a NOAEL of 0.06 mg/kg-d. An uncertainty factor of 300 was used; 10 to account for inter-species variability, 10 for human variability, and 3 for use of a short-term study to derive a chronic exposure limit.

The IRIS database (U.S. EPA 2017; last updated 1991) oral reference dose (RfD) of 4×10^{-4} mg/kg-d is based on a study in which male and female rats were administered antimony as potassium antimony tartrate in water. Over the period of the study, growth rates were not affected; however, the survival of the treated animals was reduced. Nonfasting blood glucose levels were decreased in treated males, and cholesterol levels were altered in both sexes. A decrease in mean heart weight for the males was noted. No increase in tumours was seen as a result of treatment. Since only one level of antimony was administered, a no observable effects level (NOEL) could not be determined. The lowest observable adverse effects level (LOAEL) is equal to the dose administered (0.35 mg/kg-d). An uncertainty factor of 1,000 was applied to the LOAEL (a factor of 10 each for interspecies conversion, for the protection of sensitive individuals, and because the effect level was a LOAEL not a NOEL). The overall confidence in the RfD is low. The study upon which the RfD was based used only one species and only one dose level. A NOEL was not determined, and gross pathology and histopathology were not well described.

The WHO (1996) provide an RfD of 0.00086 mg/kg-d based on a LOAEL of 0.43 mg/kg-d from a limited lifetime study where rats were exposed to antimony in drinking water at a single dose level. The toxicological endpoints were decreased longevity and altered blood levels of glucose and cholesterol. An uncertainty factor of 500 was used: 10 to account for interspecies conversion, 10 to account for human variability, and 5 because a LOAEL was used to derive the RfD.

The WHO (2003) considered the subchronic drinking water study in rats (Poon et al. 1998); however based on a re-analysis of the study by Lynch et al. (1999). The WHO (2003) used a NOAEL of 6 mg/kg-d, which corresponded to an antimony concentration in drinking water of 50 mg/L. This NOAEL is based on decreased body weight gain and reduced food and water intake. Applying an uncertainty factor of 1000 (a factor of 10 each for intra- and interspecies variation and the use of a subchronic study) resulted in a TRV of 0.006 mg/kg-d. The National Institute for Public Health and the Environment (RIVM; Van Engelen et al. 2006) also adopted this TRV as most appropriate limit value for the ingestion of antimony (Tiesjema and Baars 2009).

The only inhalation toxicity values located for antimony was specific to antimony trioxide, which is not appropriate for application in this assessment.

Table G.4 provides a summary of the TRVs for oral exposure for antimony.

As seen from the table, the U.S.EPA IRIS value of 0.0004 mg/kg-d was selected as the TRV to be used in the risk assessment. Given that the WHO (2003) evaluation of antimony is a more recent evaluation, the uncertainty analysis considers the effect on the results of using a TRV of 0.006 mg/kg-d.

Table G.4 Non-carcinogenic oral exposure limits for antimony

TRV mg/kg-d	Type	POD		Uncertainty Factors								Notes	Effects	Source
		Dose	Basis	A	H	L	S	D	I	X	Total			
0.0004	C	0.35	LOAEL	10	10	10					1000	-50 male and 50 female rats administered 5 ppm potassium antimony tartrate in water (Schroeder et al. 1970). -Male rats survived 106 and females survived 107 fewer days than controls at median lifespans. -No NOEL established since only one dose was used. -No increase in tumours was seen.	Longevity, blood glucose and cholesterol	U.S. EPA (2017; last updated 1991)
0.006	I	6	NOAEL	10	10		10				1000	- 13-week study in which rats were exposed to potassium antimony tartrate in drinking water at concentrations of 0.5, 5, 50 or 500 mg/L (Poon et al. 1998) NOAEL of 50 mg/L --> 6 mg/kg-d -no adjustment for duration from 13 week study	Decreased body weight gain and reduced food and water intake	WHO (2003)
0.00086	C	0.43	LOAEL	10	10	5					500	-Limited lifetime study in which rats were exposed to antimony in drinking water at a single dose level [same study (Schroeder et al. 1970) as cited in IRIS (U.S. EPA 2017)].	Decreased longevity and altered blood levels of glucose and cholesterol	WHO (1996)

TRV mg/kg-d	Type	POD		Uncertainty Factors								Notes	Effects	Source
		Dose	Basis	A	H	L	S	D	I	X	Total			
0.0002	I	0.06	NOAEL	10	10		3				300	-13-week study in which rats were exposed to potassium antimony tartrate in drinking water at concentrations of 0.5, 5, 50 or 500 mg/L (Poon et al. 1998) -NOAEL of 0.5 mg/L --> 0.06 mg/kg-d -no adjustment for duration from 13 week study	Histopathological changes	Health Canada (1997); value presented in technical document for the drinking water guideline

Note: Value shaded in bold used in the assessment.
POD - Point of Departure.
NOEL - No observable effects level.
LOAEL - Lowest observable adverse effects I level.

Type:
A - acute duration (< 15 days).
I - intermediate duration (>15 days to < 1 year).
C - chronic (> 1 year).

Uncertainty Factors:
A - interspecies (animal to human) variability.
H - intraspecies (human) variability.
L - use of a LOAEL to derive a TRV.
S - extrapolation from a sub-chronic to chronic TRV.
D - database deficiencies.
X – other.

G.3 Manganese

Manganese is essential for normal physiologic functioning in all animal species. Several diseases in humans have been associated with deficiencies and excesses of manganese intakes. Thus, any quantitative risk assessment for manganese must take into account aspects of both the essentiality and the toxicity of manganese. In humans, there is a lot of information about the range of essentiality for manganese. Additionally, there are many reports of toxicity, most prominently central nervous system effects similar to those resulting from Parkinson's disease, to humans exposed to manganese by inhalation; however, very little is known about the oral toxicity of manganese. Therefore, the toxicity information on oral exposures is related to safe dietary intakes.

The WHO (1973) reported the average daily consumption of manganese in diets to range from 2.0 to 8.8 mg Mn/d. Higher manganese intakes are associated with diets high in whole-grain cereals, nuts, green leafy vegetables, and tea. From manganese balance studies, the WHO concluded that 2 to 3 mg/d is adequate for adults and 8 to 9 mg/d is "perfectly safe." The Institute of Medicine (IOM 2001) set a tolerable upper intake level (UL) of 11 mg/d for adults based on a NOAEL for Parkinsonian-like neurotoxicity from Western diets. This value was adjusted for other age groups on the basis of relative body weights. A value was not derived for infants 12 months of age and younger. Health Canada refers to an Adequate Intake (AI) ranging from 0.003 mg/d for breast-fed infants; 0.6 mg/day to 2.2 mg/d for children depending on the age and sex; and for adults, 2.3 mg/day for males and 1.8 mg/day for females. The AI is the observed or estimated intake that appears to sustain a defined nutritional status (IOM 2001).

G.3.1 Pharmacokinetics

The main routes of absorption for manganese are the respiratory and gastrointestinal tracts. In the young infant, absorption of manganese is very high, approaching 99% at birth; absorption gradually decreases with age to around 5.5% in the adult (Health Canada 1979). The ATSDR (2012) indicates that the amount of manganese absorbed across the GI tract ranges from 3% to 5%. No studies ae available with respect to the amount of manganese that is absorbed by humans or animals after inhalation exposure to manganese dusts. Generally, the extent of inhalation absorption is a function of particle size (ATSDR 2012).

The major route of manganese excretion is via the bile to the feces although some excretion does occur in urine, milk, and sweat (ATSDR 2012).

Bones contain the highest amount of manganese, about 25% of the body burden; most of this seems to be deposited in the inorganic portion of the bone, which acts as a buffer. On a concentration basis, the testes, liver, pancreas and kidneys are the tissues that accumulate the most manganese (Health Canada 1979).

G.3.2 Toxicity Endpoints

In humans, inhalation of particulate manganese compounds can lead to an inflammatory response in the lung (although this may be caused by the particulate itself). This is characterized by an infiltration of macrophages and leukocytes, which phagocytize the deposited manganese particles. Damage to lung tissue is usually not extensive but may include local areas of edema. Symptoms and signs of lung irritation and injury may include cough, bronchitis, pneumonitis, and minor reductions in lung function; occasionally, pneumonia may result (ATSDR 2012).

There is some evidence of adverse cardiovascular effects after occupational exposure to manganese (ATSDR 2012).

Decreased libido and impotence are frequently observed in male workers exposed to high levels of manganese dusts in the workplace. These effects are at least partly neurological in origin; the recent human and animal studies indicate that manganese is damaging to the testes. Reproductive effects have been shown to be of concern in occupationally-exposed males and do not suggest that ambient exposure levels would be of concern to the general population. Information on reproductive effects of inhaled manganese in females is limited. The effects of excess manganese on human foetal development have not been thoroughly investigated. Studies from humans and animals suggest that high levels of manganese intake might lead to developmental effects (ATSDR 2012).

There is some evidence from a study on occupationally exposed welders that manganese may cause chromosomal aberrations; however due to inconsistencies, no overall conclusion can be made about the possible genotoxic hazard to humans from exposure to manganese compounds (ATSDR 2012).

The most sensitive and most significant effects caused by inhalation exposure to manganese dusts in the air are neurological deficits. There is clear evidence from studies of humans exposed to manganese dusts in mines and factories that inhalation of high levels of manganese can lead to a series of serious and ultimately disabling neurological effects. This disease, termed manganism, typically begins with feelings of weakness and lethargy. As the disease progresses, a number of other neurological signs may become manifest. In most cases, the symptoms were found to be irreversible, persisting for many years after exposure ceases. In addition, a syndrome of psychological disturbances (hallucination, psychosis) frequently emerges. As the disease progresses, patients develop severe hypertonia and muscle rigidity and may be completely and permanently disabled (ATSDR 2012).

Subclinical neurological effects have been observed in several occupational studies. These effects included decreased performance on neurobehavioral tests; significantly poorer eye-hand coordination, hand steadiness, and reaction time; poorer postural stability; and lower levels of cognitive flexibility. A study on environmental manganese sources, including a manganese alloy plant as a potential point source, indicates that both men and women are adversely affected by non-occupational exposure to manganese as evidenced in performance on neurobehavioral tests and increased neuropsychiatric symptoms (ATSDR 2012).

It has been suggested that these adverse health effects, especially neurologic effects, are occurring on a continuum of dysfunction that is dose-related. In other words, mild or unnoticeable effects may be caused by low, but physiologically excessive amounts of manganese, and these effects appear to increase in severity as the exposure level increases (ATSDR 2012).

G.3.3 Toxicity Reference Values

Health Canada (2010) derived oral RfDs for different life stages by dividing the IOM (2001) UL values by the body weights of the applicable life stage. The value for the infant was assumed to be the same as that for the toddler. The TRVs for infants and toddlers, children, teens, and adults are 0.136 mg/kg-d, 0.122 mg/kg-d, 0.142 mg/kg-d, and 0.156 mg/kg-d, respectively.

The IRIS database (U.S. EPA 2017; last updated 1996) provides an oral RfD of 0.14 mg/kg-d. This value is based on potential central nervous system (CNS) effects based on human chronic ingestion data. The assessment focuses on what is known to be a safe oral intake of manganese for the general human population, which was taken as 10 mg/d. As the information used to determine the RfD was taken from many large populations consuming normal diets over an extended period of time with no adverse health effects an uncertainty factor of 1 was used.

The IRIS database (U.S. EPA 2017; last updated 1993) provides an inhalation reference concentration (RfC) of $5x10^{-5}$ mg/m^3. This value is based on a cross-sectional study of male workers exposed to manganese dioxide (MnO_2) dust. Workers exposed to manganese performed worse than controls on several measures of neurobehavioral function such as visual reaction time, eye-hand co-ordination, and hand steadiness. A LOAEL of 0.15 mg/m^3 for workers and a $LOAEL_{HEC}$ (human equivalent concentration) of 0.05 mg/m^3 was developed. The RfC was developed using the LOAEL with the application of an uncertainty factor of 1000 (10 to protect sensitive individuals, 10 for use of a LOAEL, and 10 for database limitations reflecting both the less-than chronic periods of exposure and the lack of developmental data, as well as potential but unquantified differences in the toxicity of different forms of manganese). The overall confidence in the RfC is medium. Table G.5 provides a summary of the oral TRVs for manganese.

The ATSDR (2012) provides a chronic inhalation minimal risk level (MRL) of 0.0003 mg/m^3. The most sensitive and most significant effects caused by inhalation exposure to manganese dusts in the air are neurological deficits with progressive increased injury with prolonged exposures. The MRL is based on the same study as that considered by the U.S. EPA, but the point of departure was a $BMCL_{10}$ of 0.142 mg/m^3. This was adjusted for continuous exposure and divided by an uncertainty factor of 100 for human variability and to account for limitations in the inhalation database (including the lack of data on developmental effects and the potential for reproductive effects in women, and the potential for differences in toxicity from different forms of manganese).

The Office of Environmental Health Hazard Assessment (OEHHA 2016) derived a chronic inhalation reference exposure level (REL) of 9 x 10^{-5} mg/m^3, again derived from the same human occupational exposure study and using a $BMCL_{05}$ of 0.072 mg/m^3 as the point of departure. A total uncertainty factor of 300 was used.

The WHO (2000, 2006) report an annual average concentration guideline in air of 0.00015 mg/m^3, again derived from the human occupational exposure study and using a $BMCL_{05}$ of 0.03 mg/m^3 followed by adjustment to continuous exposure and incorporation of an uncertainty factor of 50.

Because all of the above values were derived from the same study, the most conservative value of 5 x 10^{-5} mg/m^3 from IRIS (U.S. EPA 2017) was selected for use in this assessment. It included an uncertainty factor of 10 to protect sensitive individuals. Table G.6 provides a summary of the inhalation TRVs for manganese.

Table G.5 Non-carcinogenic oral exposure limits for manganese

TRV mg/kg-d	Type	POD		Uncertainty Factors								Notes	Effects	Source
		Dose	Basis	A	H	L	S	D	I	X	Total			
0.136 (toddler) 0.122 (child) 0.142 (teen) 0.156 (adult)	C	11	NOAEL (food)									-Mn not considered to be carcinogenic. -Weight of evidence from human epidemiological studies. -Based on IOM (2001). -TRV based on the UL (IOM) adjusted for life stage and body weight.	Parkinsonian-like neurotoxicity	Health Canada (2010)
0.14	C	0.14	NOAEL							3**	3**	-Mn is essential for normal physiologic functioning. -Various studies report average daily intakes of Mn of 2.0-8.8 mg/day (NRC 1989; Freeland-Graves et al. 1987; WHO 1973). -U.S. EPA determined 10 mg/d (0.14 mg/kg-d) was an appropriate TRV. -2-3 mg/d is adequate for adults while 8-9 mg/d is "perfectly safe. -**recommended that if assessing risk from Mn in drinking water or soil, use a modifying factor of 3	Central nervous system effects	U.S. EPA (2017; last updated 1996)

0.00005	c	0.15	LOAEL			10		10		10*	1000	human occupational exposure study to manganese dioxide (Roels et al. 1992). -LOAEL is a time-weighted average, and is the geometric mean of individual LOAELs (based on individual work histories in years) divided by average duration of 5.3 years. -Duration adjusted for 10/20 m^3 and 5/7 days. -10* - to protect sensitive individuals	Impairment of neurobehavioural function.	U.S. EPA (2017; last updated 1996)
0.0003	C	0.142	$BMCL_{10}$		10			10			100	occupational exposure study (Roels et al. 1992). -Benchmark dose analysis on incidence data for abnormal eye-hand coordination. -Logistic model was selected as best fitting: 0.142 mg/m^3. -Duration adjusted for 8/24 h and 5/7d	Neurological Effects.	ATSDR (2012)
0.00017	A (8 hr)	0.072	$BMCL_{05}$		10		$10^{1/2}$			10	300	occupational inhalation study (Roels et al. 1992). -Exposed 8 hr/d for 0.2-17.7 (mean 5.3) years. -Duration adjusted for 5/7 days. -Benchmark dose analysis of data for eye-hand coordination and hand steadiness. -$BMCL_{05}$ from probit model for eye-hand coordination selected (indistinguishable from that for hand steadiness).	Impairment of neurobehavioural function (impairment of visual reaction time, eye-hand coordination, hand steadiness).	OEHHA (2016)

TRV mg/m^3	Type	POD		Uncertainty Factors								Notes	Effects	Source
		Dose	Basis	A	H	L	S	D	I	X	Total			
0.00009	C	0.072	$BMCL_{05}$		10		$10^{1/2}$			10	300	-Same study and derivation POD as for 8- hour value, above (Roels et al. 1992). -Duration adjusted for 10/20 m^3/d and 5/7 days.	Impairment of neurobehavioural function (impairment of visual reaction time, eye-hand coordination, hand steadiness).	OEHHA (2016)
0.00015	C	0.03	$BMCL_{05}$		10					5	50	-Same study and derivation POD as for 8- hour value, above (Roels et al. 1992). -Duration adjusted for 8/24 m^3/d and 5/7 days.	Impairment of neurobehavioural function (impairment of visual reaction time, eye-hand coordination, hand steadiness).	WHO (2000, 2006)

Note: Value shaded in bold used in the assessment.
POD - Point of Departure.
NOAEL - No observable adverse effects level.
LOAEL - Lowest observable adverse effects level.
LOAEC - Lowest observable adverse effects concentration.
Type:
A - acute duration (< 15 days).
I - intermediate duration (>15 days to < 1 year).
C - chronic (> 1 year).

Uncertainty Factors:
A - interspecies (animal to human) variability.
H - intraspecies (human) variability.
L - use of a LOAEL to derive a TRV.
S - extrapolation from a sub-chronic to chronic TRV.
D - database deficiencies.
X - other.

HUMAN HEALTH RESULTS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX H: HUMAN HEALTH RESULTS

H.1 Results for Non Cancer Causing COPC

Antimony and manganese are determined to not cause cancer. The risks for these constituents of potential concern (COPCs) are evaluated by comparing the calculated exposure estimates, or intakes, to the permissible dose. When the calculated intake is below the permissible dose, adverse effects are not expected. For the purposes of presentation, a hazard quotient is calculated to compare the estimated intakes with the permissible dose. A hazard quotient is calculated as shown in Equation H-1:

$$Hazard\ Quotient = \frac{Intake}{Permissible\ Dose} \qquad \text{(H-1)}$$

For the inhalation pathway, the air concentration is compared to a permissible air concentration to calculate the hazard quotient.

A calculated hazard quotient that is less than one indicates that the estimated intake is below the permissible dose and therefore represents a negligible risk. A hazard quotient above one indicates that the permissible dose is exceeded and the risk of an adverse health effect cannot be ruled out.

Figure H.1 and Figure H.2 provide selected results for antimony and manganese, respectively. Figure H.1 illustrates that the majority of exposure to antimony for both the Ndilo Typical Country Food Diet receptors and the City of Yellowknife Country Food Diet receptors is through the ingestion pathway; however exposures are below the safe level for all lifestages. Similarly, the intakes for manganese in Figure H.2 illustrate that the dominant pathway of exposure is ingestion. For manganese, intakes are dominated by the contribution from supermarket foods.

Table H.1 summarizes the calculated hazard quotients for antimony for the various scenarios considered in the assessment. Hazard quotients are presented by pathway (i.e., ingestion, dermal, inhalation), as well as a total hazard quotient, for each life stage (i.e., toddler, child, teen, adult, and elder). All calculated hazard quotients for antimony are below one for residential locations and considered to represent a negligible risk. The results demonstrate that after the Giant Mine and former Townsite location are remediated, the risks will also be considered negligible for antimony.

Similarly, Table H.2 summarizes the calculated hazard quotients for manganese for the various scenarios considered in the assessment. All calculated hazard quotients for manganese are below one and considered to represent a negligible risk. Measured concentrations of manganese in air were not available; therefore, this pathway was considered to be zero (0).

Note: measured air concentrations were not available for manganese.

H.2 Results for Cancer Causing COPC

Arsenic is a known carcinogen and was identified as a COPC for the HHRA. Evaluation for potential risks from exposure to arsenic is completed on an incremental basis (with the consideration of exposures above background level exposures) and on a lifetime basis, which is evaluated through the use of a lifetime receptor.

To determine the incremental risks, the background exposure was subtracted from the total exposure to determine the incremental exposure, which was used to calculate the incremental risk. The incremental risk for each life stage was used to calculate the risk to a lifetime receptor, as shown in Equation H-2:

$$Incremental\ Lifetime\ Risk\ Level = \sum_{life\ stage} Intake_{inc} \times SF \times \frac{Lifestage\ Yrs}{Lifetime\ Yrs} \quad \text{(H-2)}$$

Where:

$Intake_{in}$	=	incremental intake for life stage (mg/kg-d)
SF	=	cancer slope factor (1/(mg/(kg-d)))

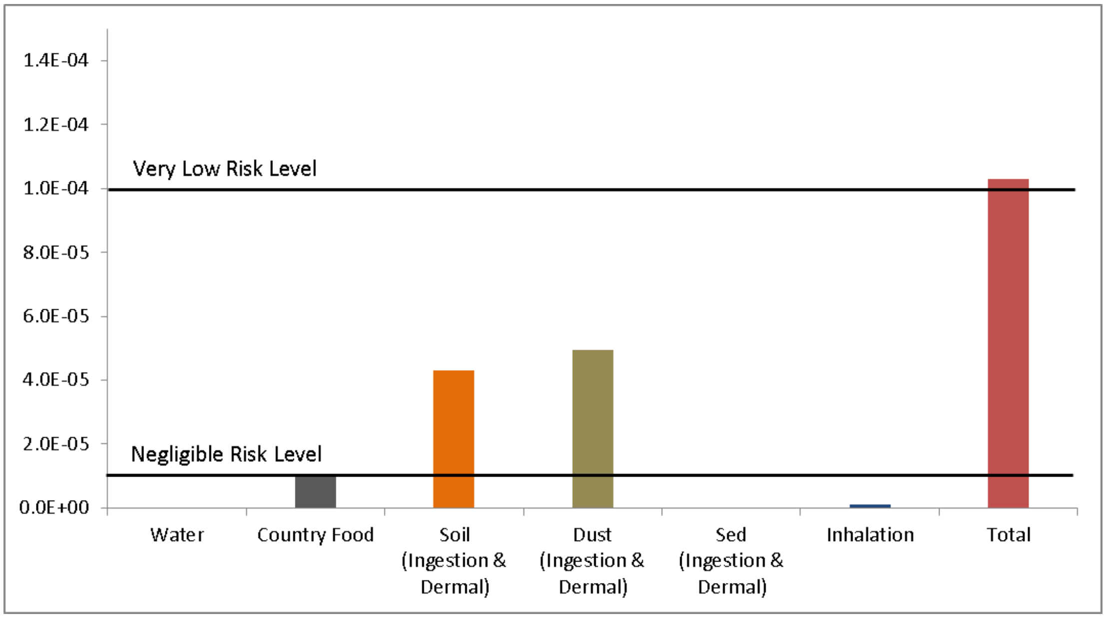
The lifetime receptor was assumed to have a total of 80 years exposure (Lifetime Yrs), with 4 years as a toddler, 6 years as a child, 8 years as a teen, 52 years as an adult, and 10 years as an elder (Lifestage Yrs).

For the inhalation pathway, the incremental air concentration was multiplied by a slope factor for air concentration to calculate the incremental risk level for air exposures.

Figure H.3 provides selected results for arsenic exposure. The lifetime risk level due to arsenic for the Ndilo Typical Country Food Diet receptors is dominated by soil and dust exposures. The consumption of country foods and inhalation of air contribute less materially to the estimated risk level, and the total estimated risk level is at the very low risk level of exposure. For the City of Yellowknife Country Food Diet receptors, the contributions to the lifetime risk level are more evenly shared between country food, soil, dust, and air; the total estimated risk level is at the negligible risk level of exposure.

Figure H.3 Selected results for arsenic

Lifetime Risk Levels for Ndilo Typical Country Food Diet



Lifetime Risk Levels for City of Yellowknife Country Food Diet

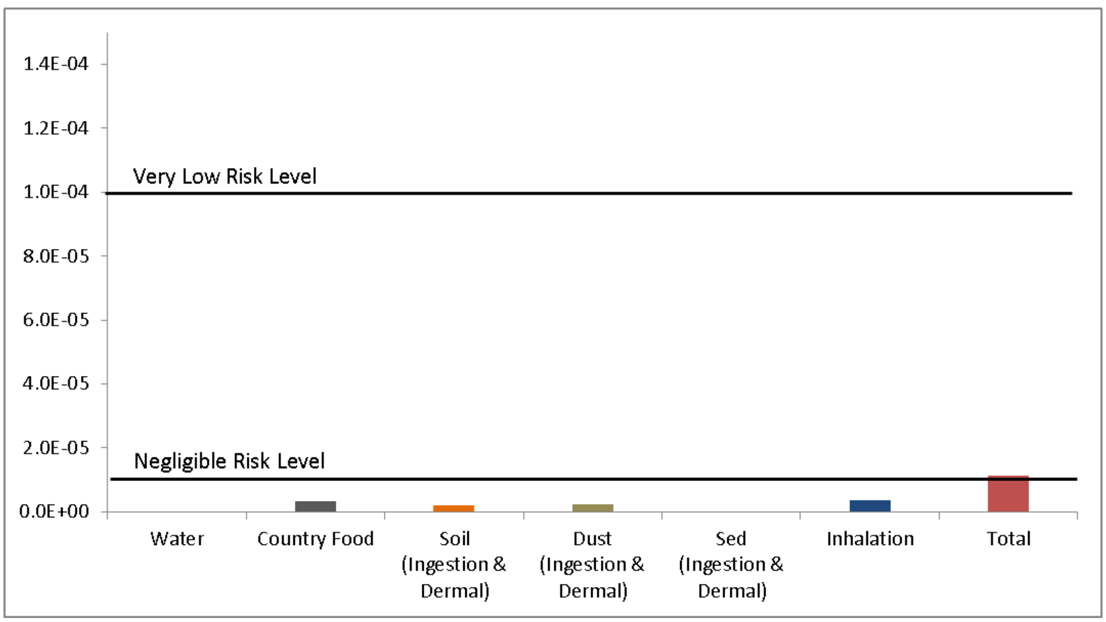


Table H.3 summarizes the calculated incremental cancer risk levels for arsenic for the various scenarios considered in the assessment. Risk levels are presented by media (i.e., water, food, soil, sediment, and air), as well as a total risk level for the lifetime receptor. Values in the table that are greater than the Health Canada's acceptable incremental lifetime cancer risk level of one-in-one hundred thousand people (1 x 10^{-5}) are indicated in **bold**; values below this level are considered negligible.

In order to provide a context for the incremental risks associated with arsenic exposure in this study, a risk framework was adopted as described in Section 3.5.2 of the main document. In this framework, risks below one-in-one hundred thousand people were considered to be negligible and risks between one-in-ten thousand (1 x 10^{-4}) and one-in-one hundred thousand people (1 x 10^{-5}) are considered to be very low. Risks above one-in-ten thousand (1 x 10^{-4}) were considered to be low risks. The results in the table indicate that the risks associated with the Giant Mine are in the negligible to very low range for most scenarios, with a few scenarios within the bottom of the low risk range. The incremental arsenic risks are dominated by soil and indoor dust exposures at Ndilo, Dettah, Latham Island, City of Yellowknife, and Ingraham Trail locations. In the future at the former Townsite location, remedial activities will reduce arsenic concentrations in soil and, under a residential scenario (most restrictive land use), the risks are considered to be in the very low range.

Note: Incremental risks above the Health Canada level of $1x10^{-5}$ are **bold**; this level represents a negligible risk.

H.3 Sample Calculation

A sample risk calculation for Ndilo Typical Country Food Diet scenario is provided in the following steps. Sample calculations for all scenarios are provided in Appendix I.

Hazard quotient via ingestion – antimony (adult):

$$Hazard\ quotient - ingestion = \frac{Total\ Intake - ingestion\left(1.0 \times 10^{-4}\,\frac{mg}{kg\ d}\right)}{TRV - ingestion\left(4.0 \times 10^{-4}\,\frac{mg}{kg\ d}\right)}$$

$$= 0.25$$

Hazard quotient via inhalation – antimony (adult):

$$Hazard\ quotient - inhalation = \frac{Air\ concentration\left(2.3 \times 10^{-6}\,\frac{mg}{m^3}\right)}{TRV - inhalation\left(2.0 \times 10^{-4}\,\frac{mg}{m^3}\right)} = 0.01$$

Hazard quotient via dermal – antimony (adult):

$$Hazard\ quotient - dermal = \frac{Total\ Dermal\left(1.9 \times 10^{-5}\,\frac{mg}{kg\ d}\right)}{TRV - dermal\left(4.0 \times 10^{-4}\,\frac{mg}{kg\ d}\right)} = 0.05$$

Total hazard quotient – antimony (adult):

$$\begin{aligned} &Hazard\ quotient \\ &\quad = Hazard\ quotient - ingestion\ (0.25) + Hazard\ quotient \\ &\quad - inhalation\ (0.01) + Hazard\ quotient - dermal\ (0.05) = 0.31 \end{aligned}$$

Incremental risk level via ingestion – arsenic (lifetime):

$$\begin{aligned} &Incremental\ risk\ level - ingestion \\ &\quad = Total\ Incremental\ Intake - ingestion\left(4.0 \times 10^{-5}\,\frac{mg}{kg\ d}\right) \times SF \\ &\quad - ingestion\left(1.8\,\frac{kg\ d}{mg}\right) = 7.1 \times 10^{-5} \end{aligned}$$

Incremental risk level via inhalation – arsenic (lifetime):

$$Incremental\ risk\ level - inhalation$$
$$= Incremental\ Air\ concentration\left((1.5 \times 10^{-6} - 1.35 \times 10^{-6})\frac{mg}{m^3}\right)$$
$$\times SF - inhalation\left(6.4\frac{m^3}{mg}\right) = 9.6 \times 10^{-7}$$

Incremental risk level via dermal – arsenic (lifetime):

$$Incremental\ risk\ level - dermal$$
$$= Total\ Incremental\ Dermal\left(1.7 \times 10^{-5}\frac{mg}{kg\ d}\right) \times SF$$
$$- dermal\left(1.8\frac{kg\ d}{mg}\right) = 3.1 \times 10^{-5}$$

Total incremental risk level – arsenic (lifetime):

$$Incremental\ risk\ level$$
$$= Incremental\ risk\ level - ingestion\ (7.1 \times 10^{-5})$$
$$+ Incremental\ risk\ level - inhalation\ (9.6 \times 10^{-7})$$
$$+ Incremental\ risk\ level - dermal\ (3.1 \times 10^{-5}) = 1.0 \times 10^{-4}$$
