EXECUTIVE SUMMARY

The Giant Mine is located in Yellowknife, Northwest Territories (NWT), about five kilometers (5 km) north of the city center. Giant Mine produced gold from 1948 until 1999, and gold ore for offsite processing from 2000 until 2004. The processing of ore produced dust containing high levels of soluble arsenic, which was pumped into sealed underground storage areas. Approximately 13.5 million tonnes of tailings were also generated that are stored in four impoundments, which cover 95 hectares of the site, in total. It is estimated that more than 20,000 tonnes of arsenic were released to the atmosphere during the operation of the mine. Other areas have been contaminated with arsenic by releases from activities at the Giant Mine. Baker Creek flows through the site in a channel that has been heavily altered to accommodate mining, ore processing, and highway construction. Both the water and sediments of Baker Creek contain high levels of arsenic, as well as other contaminants.

In 2010, the Developer's Assessment Report (DAR) for the Giant Mine Remediation Project (INAC/GNWT 2010) was submitted to the Mackenzie Valley Environmental Impact Review Board (MVEIRB) for approval to proceed with the remedial activities at the site. As part of the findings (Measure 10), MVEIRB indicated that a comprehensive quantitative Human Health Risk Assessment (HHRA) was needed before regulatory approvals would be provided. This risk assessment report has been prepared in response to Measure 10. In addition to the conduct of a HHRA, an Ecological Risk Assessment (ERA) was carried out to evaluate potential risks to wildlife and plants at the Giant Mine.

A Human Health and Ecological Risk Assessment (HHERA) is a scientific process used to describe and estimate the likelihood of potential risks (i.e., adverse health effects) to humans and wildlife and plants resulting from exposure to environmental contaminants (i.e., chemicals). The risk assessment is used to determine what the chemicals of importance are, who is being exposed, and how they are being exposed. All three of these components are considered in the assessment of risk. It should be noted that the HHRA does not provide a direct assessment of cause and effect concerning current health problems or effects. Any link between exposure and actual health effects comes from epidemiological studies, which include surveys of health problems in a community, and compares them to health problems in other cities and populations where the same type of exposure does not occur. The on-going separate Health Effects Monitoring Program is a component of these epidemiological studies.

The objective of this HHERA is to quantify the likely change in exposure and risk for people in the area, as well as for wildlife at the Giant Mine site, from exposure to arsenic and other contaminants of potential concern associated with the Giant Mine Remediation Project (GMRP). Therefore, current conditions as well as a predictive assessment of future conditions after remediation were evaluated.

Summary of Available Information

There are over 200 reports on the Giant Mine related to air quality, disturbed and undisturbed soils on the site, fish in Yellowknife Bay, and the aquatic environment in Baker Creek. The focus of the HHERA was on current conditions (2011 to 2016) at the site. Other studies are available for soils in Ndilo, Dettah, and the City of Yellowknife as well as on garden produce; the findings of these investigations were also considered in the HHRA.

The available information in these reports was examined to identify where potential data gaps exist for the risk assessment. It became apparent that a few gaps needed to be filled for the HHRA and ERA. This included data for soils and sediments at the former Townsite and Shoreline lands and the Long Lake area where people camp and swim. In addition, little data were available on plants and small animals (mice) present on the Giant Mine. A program was completed in the summer of 2016 to collect these samples.

In addition there were limited data available for country foods that are consumed by people such as wild plants (e.g., berries, mushrooms, medicinal plants) and wildlife (large game, small mammals, and birds). Thus, a program was initiated with the (Yellowknives Dene First Nation) YKDFN, North Slave Metis Alliance (NSMA), and other members of the Yellowknife community to voluntarily collect samples in 2016 as well as the spring and summer of 2017. A dietary survey was also conducted in the YKDFN and NSMA communities to collect some Traditional Knowledge as to what types and how much country food people eat, and from where they collect the country food.

Stakeholder Involvement

There has been stakeholder involvement throughout the current risk assessment process through involvement with the Giant Mine Working Group (WG). The WG is made up of members from Indian and Northern Affairs Canada (INAC), Government of Northwest

Territories (GNWT), Public Services and Procurement Canada (PSPC), Environment and Climate Change Canada (ECCC), Department of Fisheries and Oceans (DFO), City of Yellowknife, Alternatives North, YKDFN, NSMA, Health Canada, Giant Mine Oversight Board, and Bill Slater, who is a technical consultant to the WG. Before the HHRA was initiated, consultation had been undertaken to develop the basis of the assessment. During the course of the project, five meetings occurred where discussions were held with the WG on the approach and assumptions that would be used in the HHERA and findings of the dietary survey.

The study team has also had meetings with the YKDFN Giant Mine Advisory Committee (GMAC) to discuss aspects of the risk assessment and to solicit their input on the HHRA. In addition they have been consulted on the voluntary sampling program.

Members from the YKDFN and NSMA provided samples to be analyzed as part of the voluntary sampling program and also participated in the update to the dietary survey and provided valuable information that was used in the risk assessment.

Remedial Activities at Giant Mine

Arsenic trioxide waste is present in underground chambers at the site that will be frozen to create a barrier that will prevent groundwater contacting this waste. As part of the GMRP, numerous buildings have been demolished and the mill and headframe have been taken down. The GMRP has a number of remedial actions to be carried out at the Giant Mine; those that were accounted for in the risk assessment included:

- *Capping of the four tailings ponds, filling in the eight open pits, remediating contaminated soils in the disturbed areas of the site to GNWT industrial land use soil criteria, and active management of areas with arsenic concentrations greater than 3,000 mg/kg in the form of excavation and/or fencing*
- *On-going treatment of water, including the relocation of the outfall of the treatment plant from Baker Creek to a location in Yellowknife Bay near the outlet of Baker Creek.*
- *Dredging of the sediments in the section of Baker Creek downstream of the Giant Site (i.e., Reaches 0 to 6).*
- *Remediation of the soils in the former Townsite and Marina to GNWT residential criteria and dredging and covering of the sediments in the near shore.*

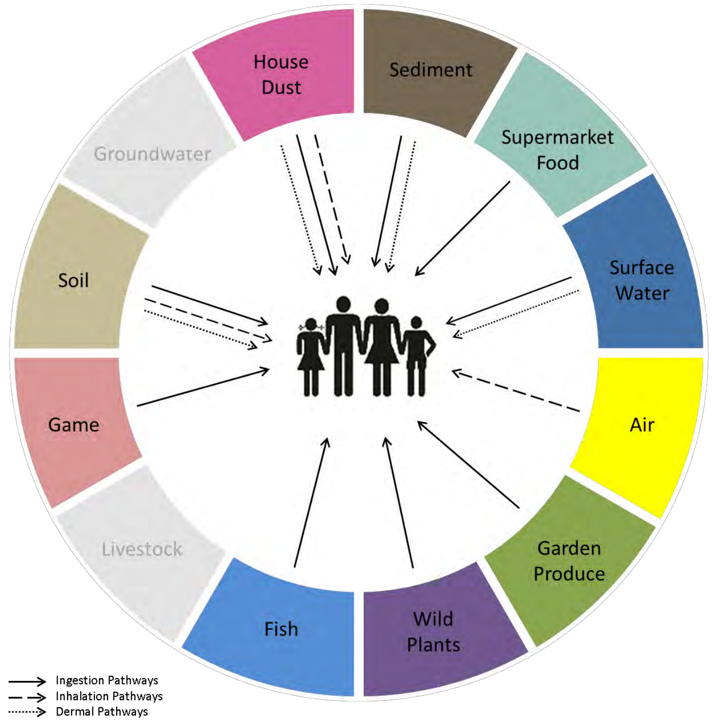
Human Health Risk Assessment

The HHRA followed guidance outlined by Health Canada (Health Canada 2010a). A screening process was used to determine which contaminants should be carried through the risk assessment process as constituents of potential concern (COPC); this process involved comparing measured concentrations in soil and water to Canadian Soil Quality and Water Quality guidelines. Arsenic and antimony were identified as contaminants of potential concern through this process. There are no guidelines for manganese in soil, and the measured concentrations were above background; thus, manganese was also identified for inclusion in the risk assessment. For evaluating current conditions, the HHRA considers risks from exposure to arsenic, antimony, and manganese to members of the public in Ndilo, Dettah, Latham Island, Ingraham Trail, and the City of Yellowknife. For the future scenario, the remedial actions associated with the GMRP were taken into account. The future scenario involved recreational use of the Giant Mine outside of the actively managed areas and a potential for residential use at the former Townsite. It is acknowledged that members of the YKDFN have indicated that they do not want to use the Giant Mine in the future; however other stakeholders have indicated a desire to do so and thus this was evaluated. The future land use has not been determined for the Townsite; however, a residential scenario represents the most restrictive land use in this area.

The HHRA took a multi-media approach, which considered exposure to COPC from all relevant environmental components such as air, dust, soil, sediment, water, and country foods. Background exposures from store-bought food and from other sources not influenced by the Giant Mine were also taken into account in the assessment.

Figure ES.1 shows the ways that people are exposed (exposure pathways) that were considered in the HHRA.

Figure ES.1 Exposure pathways for the human health risk assessment



The HHRA assumed that people drink water from a municipal supply. However, as some people have indicated that they drink water directly from Yellowknife Bay, this pathway was also evaluated. People are exposed to soil and house dust from where they live and this was considered at the various locations. Children have been reported to wade in shallow water along the shores of the Ndilo and Dettah communities as well as near the marina and other areas on Latham Island; therefore, wading was included in the assessment. Swimming and playing on the beach at Long Lake was also evaluated.

People were assumed to eat fish from Yellowknife Bay. Samples of country foods were voluntarily provided by the YKDFN, NSMA, and other community members for analysis; this information was used to evaluate the country foods that people eat. The samples provided included moose, duck, grouse/ptarmigan, rabbit, medicinal plants (including rat root), berries, and mushrooms.

People do have vegetable gardens in the area; however, it was determined that most of the soil in these gardens (which are generally raised) comes from outside of the area or is compost from the City. A previous study into vegetable gardens determined that there *was little, if any, risk for residents eating garden vegetables. Based on all these findings, garden produce was not considered further.*

Dietary Survey

Human receptor characteristics were obtained from Health Canada or other authoritative sources and include body weight, food and drinking water ingestion rates, amount of time spent outside, etc. and were defined in order to complete estimates of potential exposure. A dietary survey was completed in early 2017 to update the types and amount of food the YKDFN and the NSMA would typically eat and to gather information on areas from which food (plants, fish, game) were generally obtained.

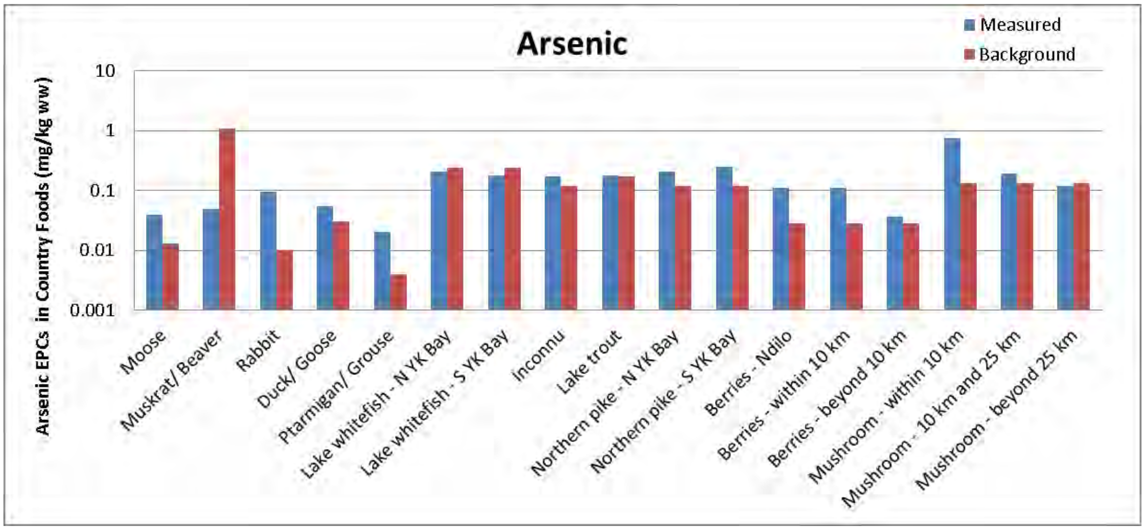
Voluntary Sampling

The voluntary sampling program for country foods was very successful, with a total of over 130 samples collected for use in the HHRA. Figure ES.2 shows a comparison between measured arsenic concentrations in various sampled media and background. The figure shows that:

- *concentrations of arsenic in moose samples are higher than background;*
- *concentrations of arsenic in beaver/muskrat meat caught more than 50 km from the Giant Mine are higher than in animals caught closer to the site;*
- *concentrations of arsenic in rabbit meat from samples close to the Giant Mine are higher than background;*
- *concentrations of arsenic in duck/goose meat are slightly higher than background;*
- *concentrations of arsenic in grouse/ptarmigan meat are higher than background;*
- *concentrations of arsenic in lake whitefish, inconnu and lake trout in North Yellowknife Bay and South Yellowknife Bay are similar to background;*
- *concentrations of arsenic in northern pike in North Yellowknife Bay are similar to concentrations in South Yellowknife Bay but are higher than background;*
- *arsenic concentrations in berries close to the Giant Mine are higher than concentrations in samples further away; and*
- *the concentration of arsenic in the mushroom samples within 10 km and 25 km of the Giant Mine are higher than background concentrations and samples from greater than 25 km from the Giant Mine are similar to background concentrations.*

Additional samples were obtained in the summer 2017 and were considered in the risk assessment.

Figure ES.2 Summary of Arsenic Concentrations in Country Foods



HHRA Results

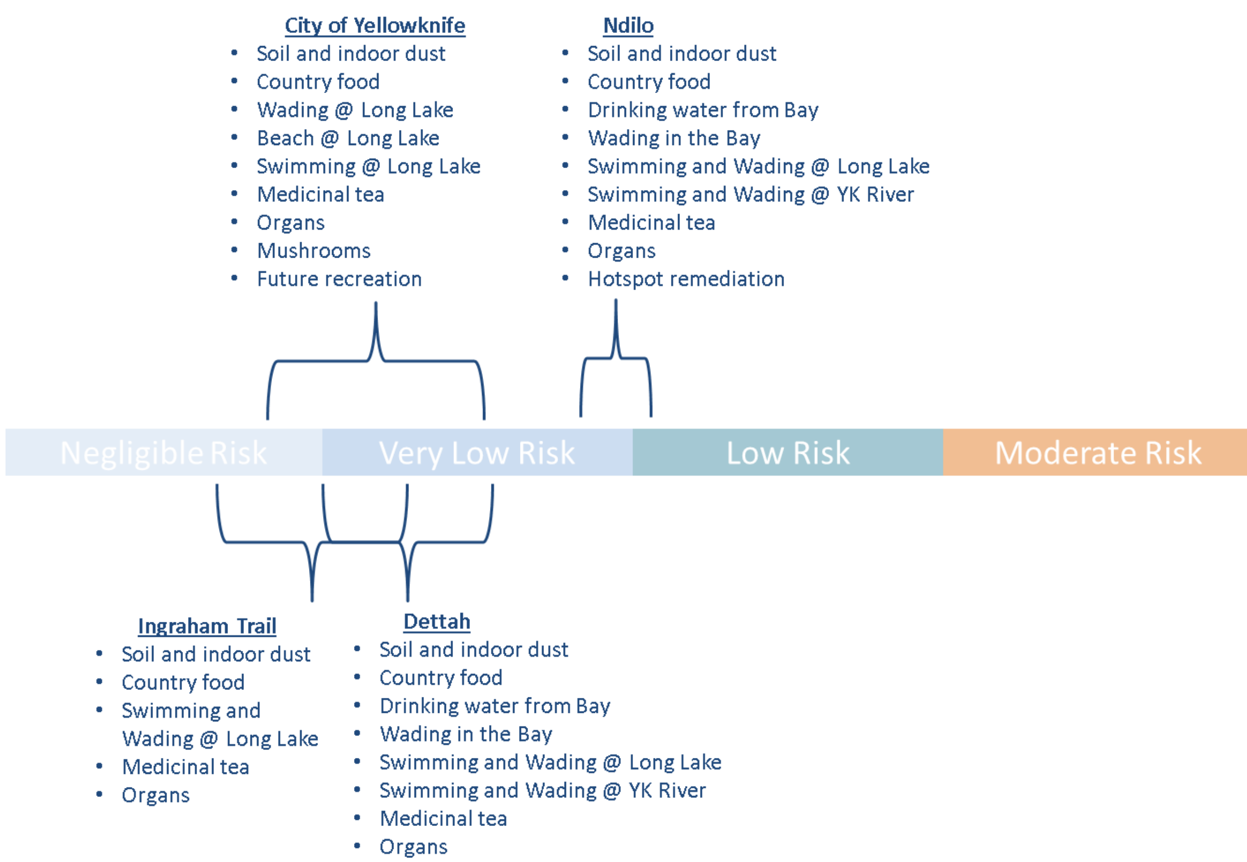
The risk assessment considered the exposure to arsenic, antimony and manganese in detail and the risks from antimony and manganese were found to be negligible. Arsenic was identified as the key concern and it is considered to cause cancer, therefore, the risk assessment evaluated the incremental, above-background, risk from exposure to arsenic in air, soil, indoor dust, water, sediment, and country foods in the area.

Figure ES.3 shows that the risks calculated are mainly within the negligible to very low risk range. For Ndilo, the calculated risks are higher than at other locations and are within the very low risk to the low risk range, which are equivalent to having x-rays or a CT scan. The incremental arsenic risks are dominated by local soil and indoor dust exposure at the various locations. Soil concentrations at Ndilo are as a result of historical contamination when the Giant Mine was in operation. Not every possible scenario was evaluated, however, it is noted that any exposure in the Yellowknife area will be within the negligible to low end of the low risk range. Risks are not expected to be any higher than the low end of the low risk range. Mushrooms within 10 km of Giant Mine have higher arsenic concentrations than background and eating these mushrooms results in risks in the very low range. Eating mushrooms from distances greater than 25 km from the Giant Mine results in negligible risks from arsenic exposure. The arsenic-

accumulating species Tricholomatacae collected within 10 km of the Giant Mine has very high arsenic concentrations and people should only eat small amounts. Eating Tricholomatacae obtained from distances greater than 25 km from the Giant Mine results in negligible risks from arsenic exposure.

For the future, after the Giant Mine has been remediated, the risks will not be changed substantially as the remedial actions at the Giant Mine will not alter the arsenic exposure across the Yellowknife area.

Figure ES.2 Summary of estimated incremental lifetime cancer risks from arsenic – current and future



In terms of the population of the City of Yellowknife, which by the 2016 census was 19,569 people, about 1 additional person in the population may develop cancer in their lifetime associated with arsenic exposure; exposure largely associated with historical contamination across the Yellowknife area. It should be noted that the nature of risk assessment is to generally over-estimate actual exposures. Therefore, actual cancer incidence associated with the Giant Mine may be less than indicated here.

Currently the members of the public do not have access to the Giant Mine site. In the future, after the Giant Mine has been remediated, there may be the potential for people to access the portions of the site which are not being actively managed for recreational use (such as hiking). This activity will not result in any increase in risk than is already occurring in the Yellowknife area. It is noted that the YKDFN do not want to use the site in the future. In addition, at the former Townsite location, remedial activities will reduce arsenic concentrations; even under a residential scenario (most restrictive land use), the risks are considered to be very low.

HHRA Recommendations

It is recommended that post-remediation sampling be completed to confirm that concentrations in the future Townsite are similar to the post-remediation values assumed in the risk assessment.

In addition, as the risks in Ndilo are higher than in other areas as a result of historical activities when the Giant Mine was in operation, consideration should be given to developing a remedial action plan for soil clean-up in the community. The sensitivity analysis demonstrated that soil clean-up will reduce risks in Ndilo. Additional soil sampling should be carried out at Latham Island to determine whether the concentrations in the soil are similar to those assumed in the risk assessment.

Finally, it is recommended that the results of the HHRA be used to inform the Health Effects Monitoring Program.

Ecological Risk Assessment

The ERA followed guidance outlined by Environment and Climate Change Canada (ECCC) from their Federal Contaminated Sites Action Plan (FCSAP) Ecological Risk Assessment guidance document (FCSAP 2012a). The Giant Mine was divided into four areas, or quadrants, in order to focus the evaluation on the areas where remediation was occurring. A number of different ecological receptors were selected, ranging from small animals that have limited home ranges, such as mice, to larger animals that could roam across the Giant Mine, such as a lynx or a fox. Plants that grow on the site were also considered. Very large animals such as moose, caribou, and bear were not considered as the Giant Mine only occupies a very small portion of the area in which they would roam. Additionally, previous assessments have indicated that these larger animals are not at *risk. Fish, aquatic plants, insects, and small animals (muskrat, mink) that are present in the water and sediment of Baker Creek were also considered.*

For the future scenario, a simple fate and transport model was used to estimate post-remediation water and sediment concentrations in Baker Creek and Yellowknife Bay. For the Giant Mine, the remedial actions associated with clean-up of the soils in the disturbed areas to GNWT industrial criteria were used to determine the future soil conditions at the Giant Mine.

ERA Results

There are elevated levels of arsenic in the sediment of Yellowknife Bay, especially in Back Bay. Although there is remediation planned for sediment along the shore near the Giant Mine, this will have limited impact on the future sediment concentrations in Yellowknife Bay as a whole. However, the conditions in Yellowknife Bay are expected to improve over time, albeit slowly.

The ERA found that there are effects on aquatic biota, such as invertebrates and fish, in Baker Creek due to current conditions. There will be some improvement with remediation, but there is a large upstream load that will cause concentrations of arsenic and antimony in Baker Creek to remain elevated post-remediation. Dredging of sediments will destroy habitat, but it will recover over time. However, the relocation of the treatment plant effluent to the mouth of Baker Creek will change the flow, and Baker Creek may be dry during the summer months. The remediation activities will affect how the creek will be used by fish and wildlife in the future.

At the Giant Mine, the assessment determined that there is the potential for the smaller animals at the site to be affected by arsenic and antimony. This is a particular concern for those animals that consume insects. As animals can adapt to living in areas of high concentrations, the effects may not be as significant as predicted. The remediation will improve the situation, but adverse effects are still predicted in the future.

ERA Recommendations

Based on the results of the ERA, the following activities are recommended:

- *completion of biological studies to examine the health of vegetation at the site;*
- *collection of insect data to verify assessment assumptions; and*

- *examination of any differences in abundance and diversity of vegetation and mammals, particularly small mammals (shrews at terrestrial sites and muskrat in aquatic environments) by conducting biological surveys at the site compared to an appropriate reference area.*

Significant changes are expected to habitats at the site due to remedial activities. It is recommended to update the wildlife surveys, including the presence of species at risk, after the remediation activities are completed. It is also recommended to complete post-remediation monitoring to determine whether any adverse effects are occurring in ecological species.

GLOSSARY

Term	Description
Assessment Endpoint	A quantitative or quantifiable expression of the environmental value considered to be at risk in a risk assessment.
Background	The typical level of a chemical present in naturally occurring or uncontaminated areas. For example, background concentrations of arsenic and other metals are higher in Yellowknife due to the geology of the area (Greenstone Belt).
Benchmark	A standard by which something can be measured or judged.
Bioavailability	The fraction of an administered dose that reaches the central blood compartment from the gastrointestinal tract.
Bioaccessibility	The quantity or fraction, which is released from the food matrix in the GI tract and becomes available for absorption.
Biota	The animal and plant life of a region.
Cancer	A disease that happens when cells in the body begin to grow and multiply out of control.
Cancer Risk Level	A term uses to describe the likelihood that someone will develop cancer over a 70-year lifetime.
Carcinogen	An agent that has the potential to cause cancer.
Cautious	As used in the term cautious estimates, this is considered a pessimistic or an over-estimate of the level, effect or hazard, as the case may be.
Constituent	A substance that has the potential to alter the natural composition of air, water or soil.
Dermal	Refers to skin.
Dose	The amount of a substance to which a person or ecological receptor is exposed over some time period. Dose is a measurement of exposure.
Ecological Risk Assessment	The application of a formal framework, analytical process, or model to estimate the effects of human actions(s) on a natural resource and to interpret the significance of those effects in light of the uncertainties identified in each component of the assessment process. Such analysis includes initial hazard identification, exposure and dose-response assessments, and risk characterization.
Environmental Impact	A change in environmental conditions resulting from an action or development, which may be negative, positive, or neutral.
Exposure	The amount of a pollutant (chemical) present in a given environment that represents a potential health threat to living organisms.
Exposure Pathway	The path from sources of COPC via air, soil, water, or food to man and other species or settings.

Hazard	Potential for exposure to radiation, a chemical, or other COPC to cause illness or injury to humans or ecological receptors. Hazard identification of a given substances is an informed judgment based on verifiable toxicity data from animal models or human studies.
Hazard Assessment	Evaluating the effects of a COPC or determining a margin of safety for an organism by comparing the concentration, which causes toxic effects with an estimate of exposure to the organism.
Hazard Quotient	The ratio of estimated site-specific exposure to a single chemical from a site over a specified period to the estimated daily exposure level at which no adverse health effects are likely to occur.
Hepatotoxicity	A general term for liver damage.
Human Health Risk Assessment	The evaluation of whether there is likely to be an adverse health effect caused by the potential exposure to COPC in the environment.
Incremental	Increase in a concentration of some chemical or radionuclide over background conditions as a result of human activities.
Ingestion	Refers to swallowing.
Inhalation	Refers to breathing in air into the lungs.
Lifetime receptor	A theoretical person representing all life stages from infant to an adult, which is used to assess the risk of developing cancer. The lifetime receptor is used because often it takes a long time between exposure to a chemical and the development of cancer.
Line of evidence (LOE)	Any pairing of exposure and effects measures that provides evidence for the evaluation of a specific assessment endpoint.
Lowest Observed Adverse Effect Level (LOAEL)	The lowest concentration or amount of a substance, found by experiment or observation, which cause an adverse effect in a target organism distinguishable from normal (control) organisms of the same species and strain.
Measurement Endpoint	A quantitative summary of the results of a toxicity test, a biological monitoring study, or other activity intended to reveal the effects of a substance.
Modelling	Using mathematical principles, information is arranged in a computer program to model conditions in the environment and to predict the outcome of certain operations.
Morbidity	Occurrence of a disease or condition that alters health and quality of life.
Mortality	Death.
Negligible	Refers to a level of risk that is not expected to result in an adverse health effect.

No Observed Adverse Effects Level (NOAEL)	The highest tested dose of a substance that has been reported to have no harmful effects on people or animals.
Nephrotoxicity	A general term for kidney damage.
Neurotoxicity	A general term for nervous system effects.
Oral	Refers to the mouth.
Permissible Dose	Considered to be a safe level of exposure as it is the amount of a chemical that someone can be exposed to over a lifetime that does not result in an adverse health effect.
Pathway	The physical course a chemical or pollutant takes from its source to the exposed organism.
Pathways Analysis	A method of estimating the transfer of chemicals (i.e., radionuclides released in water) and subsequent accumulation up the food chain to fish, vegetation, mammals and humans and the resulting dose to humans.
Receptor	A human or ecological entity exposed to a COPC released to the environment.
Risk	A measure of the probability that damage to life, health, property, and/or the environment will occur as a result of a given hazard.
Risk Assessment	Qualitative and quantitative evaluation of the risk posed to human health and/or the environment by the actual or potential presence and/or use of specific COPC.
Safe	Implies low or negligible risk.
Toxicological Reference Value	A value/criterion used to judge whether a predicted exposure may potentially have an adverse effect on human and/or ecological species.
Transfer Factor (TF)	An empirical value that provides a measure of the partitioning behaviour of a chemical or substance between two environmental media that is used to estimate concentrations in one environmental medium based on concentrations in another.
Trophic Level	The position an organism occupies on the food chain.
Uncertainty	A quantitative expression of error.
Uptake	The process/act by which a chemical enters a biological organism (e.g., inhalation, ingestion by humans, etc.).
Weight-of-Evidence	An approach for interpreting and integrating scientific information from different lines of investigation.

1.0 INTRODUCTION

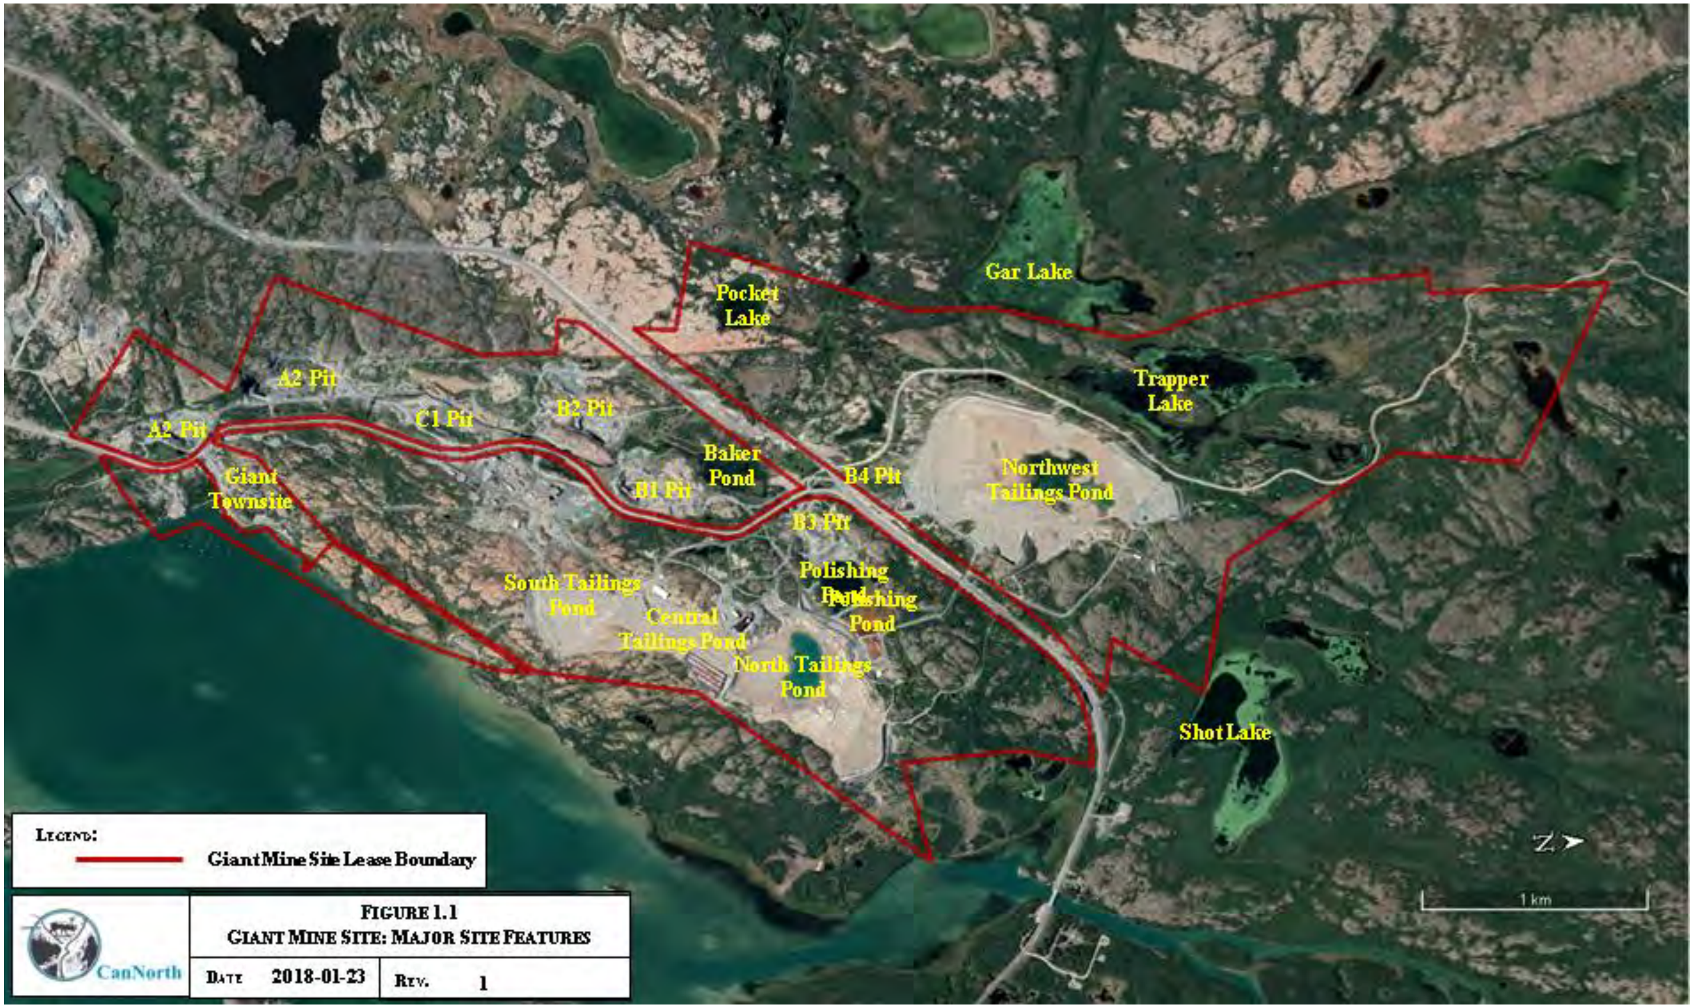
The Giant Mine is located in Yellowknife, Northwest Territories (NWT), about five kilometers (5 km) north of the city center. The mine produced gold from 1948 until 1999, and gold ore for offsite processing from 2000 until 2004. The gold in the ore is associated with an arsenic-bearing mineral known as arsenopyrite, and the roasting process used to liberate the gold led to production of arsenic-rich gases. During the initial years of operation, arsenic was released to the atmosphere without control. With the installation of emission control technologies, arsenic emissions were gradually reduced over time; however, it is estimated that more than 20,000 tonnes of arsenic were released to the atmosphere during the operation of the mine.

From 1951 to 1999, the arsenic-rich gases were captured in the form of arsenic trioxide dust. Approximately 237,000 tonnes of the dust was pumped into sealed underground storage areas. The dust is approximately 60% arsenic, which is hazardous to both people and the environment. In addition, the form of arsenic present in the dust is soluble; therefore, it could dissolve in any water that comes into contact with the dust and could then be transported to Baker Creek or Great Slave Lake, via surface runoff and groundwater migration.

The roasting process also produced tailings that contain arsenic, mostly in the form of arsenopyrite, but also in more soluble forms. A total of approximately 13.5 million tonnes of tailings are stored in four impoundments, which together cover 95 hectares (ha) of the site. Other areas have been contaminated with arsenic by emissions from the processing facilities, tailings spills, and mine rock usage for construction. There are 8 open pits and 35 openings to the underground mine. Baker Creek flows through the site in a channel that has been heavily altered to accommodate mining, ore processing, and highway construction. Both the water and sediments of Baker Creek are contaminated with arsenic. Figure 1.1 provides an overview of the Giant Mine, showing the major features on the site.

There have been several risk assessments completed at the Giant Mine since 2002 as part of the remedial planning exercises for the Giant Mine Remediation Project (GMRP). These assessments only focused on arsenic as the contaminant of potential concern. The assessments considered different areas, including the Giant Mine itself, as well as the surrounding areas, such as the City of Yellowknife, Latham Island, Ndilo, and Dettah.

Figure 1.1 Major site features at Giant Mine



In 2010, the Developer's Assessment Report (DAR) for the GMRP (INAC/GNWT 2010) was submitted to the Mackenzie Valley Environmental Impact Review Board (MVEIRB) for approval to proceed with the remedial activities at the site. As part of the findings (Measure 10), MVEIRB indicated that a comprehensive quantitative Human Health Risk Assessment (HHRA) was needed before regulatory approvals would be provided. This risk assessment report has been prepared in response to Measure 10. In addition to the conduct of a HHRA, an Ecological Risk Assessment (ERA) was carried out to evaluate potential risks to wildlife and plants at the Giant Mine.

1.1 Definition of a Human Health and Ecological Risk Assessment

A Human Health and Ecological Risk Assessment (HHERA) is a scientific process used to describe and estimate the likelihood of potential risks (i.e., adverse health effects) to humans and ecological receptors resulting from exposure to environmental contaminants (i.e., chemicals). Figure 1.2 demonstrates that HHERA is a stepwise process to answer:

- What are we concerned about? – what are the chemicals of concern.
- Who is being exposed? – people, wildlife, or vegetation.
- How are they being exposed? – what are the exposure pathways.

All three of these components must be present in order for there to be a risk. It should be noted that the HHRA does not provide a direct assessment of cause and effect concerning current health problems or effects. Any link between exposure and actual health effects comes from epidemiological studies, which include surveys of health problems in a community, and compares them to health problems in other cities and populations where the same type of exposure does not occur. The separate Health Effects Monitoring Program which is on-going is a component of these epidemiological studies.

1.2 Objective

The objective of the HHERA is to quantify the likely change in exposure and risk for people in the area as well as wildlife at the Giant Mine site from exposure to arsenic and other Constituents of Potential Concern (COPC) associated with the GMRP. Therefore, a current, as well as a predictive, assessment of future conditions after remediation and 100 years into the future are evaluated. Background exposures from store-bought food and from other sources not influenced by the Giant Mine are also taken into account in the assessment.

Figure 1.2 Schematic of risk assessment process

The risk assessment is being conducted to respond to concerns from the public and nearby communities as to the residual risks to humans and wildlife after the remedial actions at the Giant Mine have been implemented, as well as to address Measure 10 from MVREIB. Appendix Q indicates how the HHERA fulfils the requirements specified in Appendix F of the Report of Environmental Assessment.

1.3 Site Description

The Giant Mine is within the boundaries of the City of Yellowknife and is situated on Commissioner's Land administered by the Government of Northwest Territories' (GNWT) Department of Municipal and Community Affairs (MACA). The lease boundary is provided on Figure 1.1. The total area of the site is approximately 949 ha.

The Giant Mine falls within the Akaitcho Dene asserted territory and is in the vicinity of the Yellowknives Dene First Nation (YKDFN) communities of Ndilo and Dettah. The

Giant Mine is also within the traditional land use area of the Tłįchǫ, known as Monfwi Gogha De Niitlee, and it falls within the provisions of the Tłįchǫ Agreement (2003).

Ownership of Giant Mine changed hands several times prior to its last owner, Royal Oak Mines Inc., which went into receivership in 1999. At that time, control of the property was transferred to the federal department of Indian and Northern Affairs Canada (INAC) now known as Indigenous and Northern Affairs Canada, which assumed responsibility for the site. In addition, as the administrator of the lands upon which Giant Mine is located, the GNWT has also assumed responsibility for various aspects of the site. By virtue of their shared responsibilities, INAC and the GNWT are Co-Proponents of the GMRP.

1.3.1 Physical Setting and Surrounding Land Use

The Giant Mine is located approximately 5 km north of the Yellowknife city centre. Yellowknife has a population of about 19,600, according to the 2016 census. Currently, some of the buildings at the Giant Mine have been removed. The roaster complex has been consolidated into containers and placed on the central tailings until the final decision has been made for disposal. The results from the Surface Design Engagement (SDE) process will be considered by the GNWT and/or the City in finalizing the plans for the future use and development of the site.

The region surrounding Giant Mine is characterized by cool summers, very cold winters, and low humidity. Over the last 10 years (2007 to 2016), the average annual temperature has been -3.7°C; the coldest month is January and July is the warmest month (ECCC 2017). Over this same period the annual precipitation has been 285 mm, with 176 mm as rain and 152 cm of snowfall (ECCC 2017). The average wind speed recorded at the Yellowknife airport between 1971 and 2000 was 14 km/hr (INAC/GNWT 2010). Yellowknife’s monthly average wind speed varies little during the year with a range of 13 km/hr to 16 km/hr. North-westerly winds are most frequent during the winter and early spring, south-easterly winds dominate the summer months and easterly winds are frequent in the fall.

In general, the terrestrial habitat on and in the near vicinity of Giant Mine has been degraded by industrial impacts and proximity to urban development. However, some wildlife habitat is available and non-resident species use the site as a travel corridor to more favourable environments.

The aquatic habitat of the Giant Mine is dominated by Baker Creek, which runs through the Giant Mine lease area before entering Great Slave Lake on the western shoreline of Yellowknife Bay. The environmental quality of the creek has been adversely affected by historic mining operations, as evidenced by elevated arsenic concentrations in water and sediments, as well as by lower benthos diversity. Nonetheless, the creek currently serves as habitat for a variety of fish species, muskrats, and aquatic birds.

1.3.1.1 Terrestrial Environment

Yellowknife and the area around the Giant Mine lie on the border of two Level IV ecoregions termed the Great Slave Upland and Great Slave Lowland (INAC/GNWT 2010). These ecoregions have largely discontinuous permafrost, and the forests consist primarily of jack pine and black spruce stands on nutrient-poor soils. The physical topography consists predominantly of exposed bedrock with discontinuous till and thin soils over bedrock. Mixed stands of jack pine, aspen, white spruce, and birch are also common forest types within the region. Wetlands are a dominant feature.

Golder Associates Ltd. (Golder) completed a land cover classification for the Giant Mine (Golder 2016a). The total area covered by this classification survey was 15.3 km^2. Different land cover types were determined using supervised classification from available 2009 orthophotography and Light Detection and Ranging (LiDAR) data. The classification includes uplands with forest, exposed bedrock, disturbance, and regenerating disturbed areas. Lowland portions of the study area are dominated by peat bogs, lakes, streams, and accompanying shoreline vegetation. A summary is provided in Table 1.1.

Table 1.1 Different land classifications of the site

Land Classification	Coverage
Disturbance	19%
Disturbance with secondary growth	3%
Exposed bedrock	27%
Forest	32%
Open water	7%
Peat bog	6%
Shoreline vegetation	4%
Tailings pond	2%

1.3.1.2 On-Site Aquatic Environment

Baker Creek originates approximately 25 km upstream and northwest of the Giant Mine at Duckfish Lake, from where it flows in a south and southeasterly direction through a series of wetland ponds and bedrock outcrops and into a marsh that is separated by a breakwater from Yellowknife Bay of Great Slave Lake. Baker Creek is the dominant surface water feature at the Giant Mine where the creek channel has been heavily altered to accommodate mining, ore processing, and highway construction. The ridges on either side of Baker Creek are about 10 m to 20 m high with very little soil on the ridge slopes (Golder 2013a). Trapper Creek is a tributary of Baker Creek and is on the Giant Mine surface lease.

Baker Creek consists of lotic habitat, and depths vary along the creek from a few centimeters to 2.3 m deep. There is a large marsh area at the mouth of Baker Creek where it flows into Yellowknife Bay and sediments in this location consist primarily of fine material (silt and sand), which is typical of a depositional area (Golder 2013a).

Peak discharge for Baker Creek occurs during spring freshet, which is typically in May. Flow volumes in the creek are variable and the annual hydrographs for Baker Creek show that flow drops to zero almost every year during the winter, and that similar low flow conditions may occur under open-water conditions in the summer (Golder 2013a). Currently, treated water from the Giant Mine effluent treatment plant is discharged into Baker Creek during the summer months.

For monitoring and remediation design purposes, the lower portion of Baker Creek (approximately 3.5 km in length) that flows through the Giant Mine lease area has been divided into seven (7) reaches (Reach 0 to 6) based on major changes in creek hydraulics or channel conditions (INAC/GNWT 2010). The Baker Creek reach boundaries are shown in Figure 1.3, and the characteristics are summarized in Table 1.2. Reach 0 is located at the mouth of Baker Creek, where it flows into Yellowknife Bay (Back Bay) behind a constructed breakwater. Reach 6 includes Baker Creek Pond where mine effluent was discharged during mine operations and where treated effluent is currently discharged seasonally (typically during open water between July and September). Figure 1.3 shows the path of Baker Creek across the site along with the identification of the different reaches of the creek. It should be noted that the upper portion of Baker Creek on the Giant Mine Lease includes Reach, 7, 8 and 9; however, they are not affected by the remediation plan as they are up stream of any inputs from Mine activities. Reach 10 and 11 are not on the Giant Mine lease area.

As an emergency flood prevention measure, Reach 4 was realigned into a new channel in the summer of 2006 to mitigate against the possibility of surface water flow reaching the underground mine workings in the area around Mill Pond (INAC/GNWT 2010). The realignment also included the creation of habitat features that allowed for upstream fish passage.

Studies conducted since the realignment of Reach 4 have shown that the modifications markedly improved the spawning success of arctic grayling within the Creek in the spring. The large gravel present in the creek bed is well suited for concealing eggs until they hatch and Baker Creek is the only identified grayling spawning habitat in the Yellowknife area. Baker Creek has been deemed a "closed fishery" by the Department of Fisheries and Oceans in the hopes of restoring the arctic grayling population.

Figure 1.3 Baker Creek and its various reaches

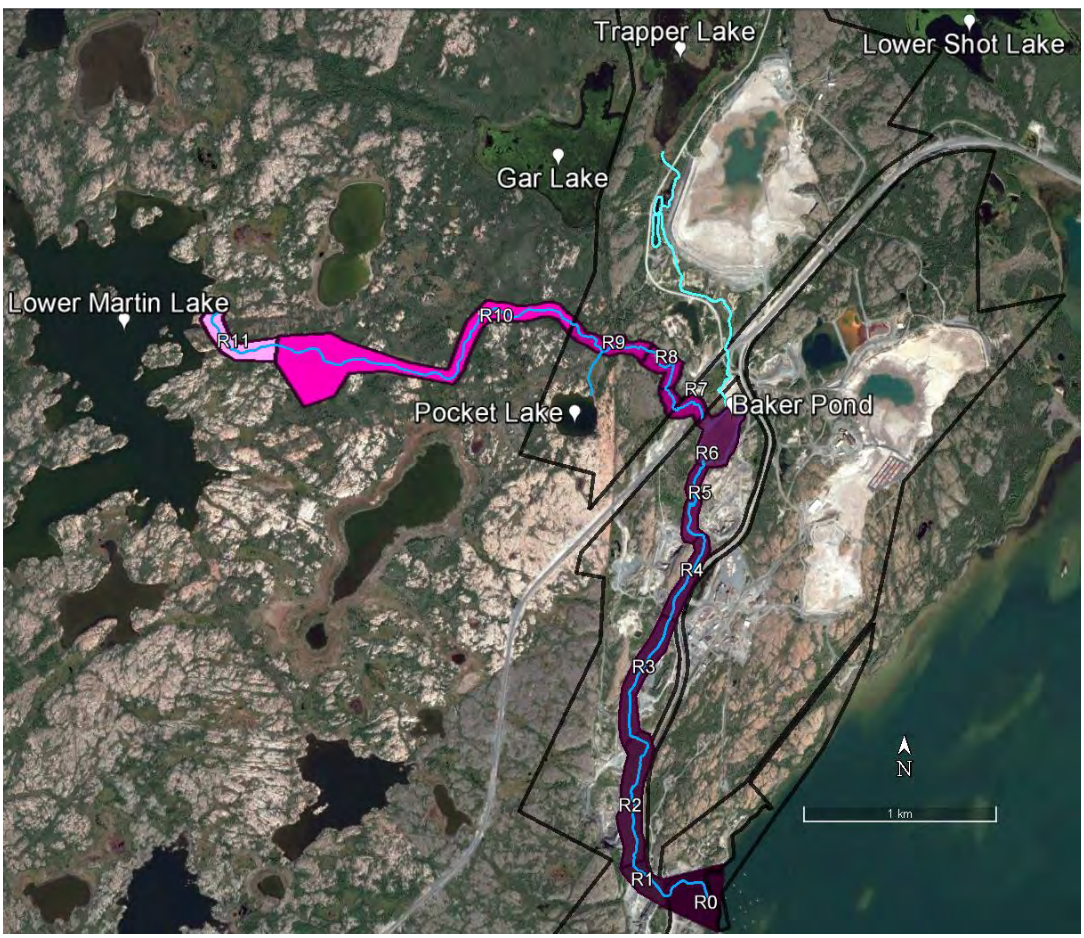


Table 1.2 Description of Baker Creek reaches

Reach	Description	Current Condition
0	Extends from just upstream of Yellowknife Bay, where the creek flows into Great Slave Lake.	Mostly marshy. A large area of vegetation.
1	Extends from marsh in Great Slave Lake to the channel north of A2 Pit; riparian vegetation is sparse and poor; channel structure and diversity is low.	395 m total length bedrock and degraded channel.
2	Straight reach that is physically undisturbed from historical mine activities; large part of riparian area is intact.	600 m total length natural channel.
3	Extends from north end of C1 Pit downstream to upper end of Reach 2; short alluvial section below culvert; aquatic habitat and riparian habitat poor.	750 m total length bedrock channel.
4	Extends upstream to the weir next to B1 Pit and downstream to below the former location of the old bridge north of C1 Pit; original channel physically disturbed and modified by contaminated sediments; in 2006, relocated to a new channel.	350 m total length. Man-made channel designed to provide conveyance and fish habitat features.
5	Extends from the former location of the old weir to the outlet of Baker Creek; moderately disturbed by mining activity in stream bed and riparian areas.	425 m total length degraded backwater-type channel.
6	Baker Pond, and includes Trapper Creek; lake bottom and shoreline contains contaminated mine tailings; discharge point for effluent.	Approximately 3.8 hectares of Pond.

Note: Adapted from INAC/GNWT (2010) and Golder (2013a).

In the spring of 2011, there was an unexpected water diversion event in Baker Creek. Over the winter, ice built up above Reach 6 for a distance of about 1 km, and in the spring (May 2011), the water from Martin Lake flowed around the ice creating a new channel and entered Reach 6 in a location where historically deposited mine tailings were present. This resulted in short-term high turbidity throughout the downstream portion of Baker Creek and the sediment plume was located as far as the mouth of Baker Creek. Remedial activities were undertaken to correct the flow path and monitoring was undertaken to determine the extent of the impacts in Baker Creek. The conclusion was that sediments and tailings from above Baker Creek Pond had likely deposited throughout Baker Creek and may remain in place or be flushed further downstream in the spring or during discharge of treated effluent (Golder 2013a).

Pocket Lake is a small headwater lake (4.8 ha) located in the southern portion of the Baker Creek watershed at the edge of the Giant Mine lease boundary. It has a small (less than 5 ha) catchment area that includes exposed bedrock (approximately 78% of the basin) and a soil-filled valley to the south (22%) (Thienpont et al. 2016). It does not have tailings or mine wastes present but has been impacted by historical roaster emissions and site runoff. Recent water quality has been measured at 2,070 µg/L arsenic, while surface sediment concentrations are 806 µg/g; these are elevated concentrations and extensive impacts on aquatic biota in the lake were observed (Thienpont et al. 2016).

Trapper Lake is a relatively large, shallow lake (less than 1 m in depth) located on the Giant Mine Site. Stantec (2015a) found arsenic levels measured up to 235 µg/L in the water and 1,060 mg/kg in the sediment. A fish habitat assessment of Trapper Lake found that it lacks adequate habitat features to directly or indirectly support life processes for freshwater fish. Trapper Creek is the largest tributary to Baker Creek in the vicinity of the mine and enters Baker Creek just upstream of the water treatment plant discharge point. Trapper Creek is monitored at two locations: the outlet of Trapper Lake and immediately upstream of Baker Creek. Monitoring at two locations is undertaken to measure the effects, if any, of seepage from the Northwest Pond on Trapper Creek water quality. Trapper Creek upstream of Trapper Lake was observed to consist of dry channels that did not show evidence of sustained flow.

A study on Trapper Creek (Stantec 2014a) found that the water was hard with neutral pH and higher conductance and total phosphorus than Upper Baker Creek. Several metals exceeded their water quality guidelines for the protection of aquatic life, including arsenic, aluminum, and iron. Arsenic and chromium also exceeded the sediment quality guidelines.

1.3.1.3 Tailings Ponds and Water Treatment Facility

At the Giant Mine, water is pumped from the mine throughout the year and is stored in the Northwest Tailings Pond before treatment and discharge to the environment. The Northwest Pond holds about 900,000 m^3 at the maximum operating level, with a maximum pond depth of 5 m. Arsenic concentrations in the pond water are typically around 15 mg/L and can vary from 10 mg/L to 20 mg/L. Besides the pumped discharges from the mine and the dam seepage collection systems, the tailings ponds also receive inputs of water from direct precipitation and runoff.

The Settling and Polishing Ponds form part of the current water treatment system and have been in place since 1981. The effluent treatment plant (ETP) operates within requirements of Metal Mining Effluent Regulations (MMER) and expired Water License (there is no current water licence for discharge). The ETP is typically well below the Maximum Authorized Monthly Mean Concentration allowed under MMER of 0.5 mg/L for arsenic. The water quality in the Polishing Pond normally has total arsenic concentrations below 0.4 mg/L.

The Northwest Tailings Pond along with the Settling and Polishing ponds are part of the active engineered water treatment system. The other tailings ponds (North, South and Central) are all dry areas with the exception of a small area in the North Tailings Pond.

1.3.1.4 Off-Site Aquatic Environment (Yellowknife Bay and Great Slave Lake)

Giant Mine is situated along the northeast shoreline of Yellowknife Bay on Great Slave Lake. Yellowknife Bay receives drainage from the Yellowknife River at its north end and extends approximately 18 km before opening into Great Slave Lake.

Yellowknife Bay receives drainage from Baker Creek, which traverses the Giant Mine. Tailings from the floatation process were discharged to the shore of Yellowknife Bay for the first three years of operation (now called the Historic Foreshore Tailings) before being held in a tailings pond on the site. The characteristics of the nearshore sediments of Yellowknife Bay are dominated by sand, while the deeper sediments have a large proportion of silt/clay and possibly fines (INAC/GNWT 2010).

Great Slave Lake is one of the largest lakes in North America (28,568 km^2) and is considered to be the deepest lake, with an average depth of 73 m and a maximum depth of 614 m (Mackenzie River Basin Board [MRBB 2003]). In general, Great Slave Lake is considered to be low in nutrients, alkalinity, hardness, and conductivity (INAC/GNWT 2010).

1.3.2 Site Geology and Hydrogeology

The Giant Mine is located within the Archean-aged Yellowknife Greenstone Belt (YGB), located in the southeast corner of the Slave Province and extends north from Great Slave Lake for almost 50 km. The YGB is bounded to the west by younger rocks composed of granite and to the east by silica-bearing sedimentary rocks. Therefore, portions of the Giant Mine contain exposed bedrock of the YGB formation.

The altered volcanic rocks of YGB are bounded to the west by granodioritic plutonic rocks that are in fault contact and bounded to the east by unconformably overlying sedimentary rocks along the shoreline of Yellowknife Bay. The main ore bodies of Giant Mine are hosted within a major brittle-ductile shear system that crosscuts the Kam Group of volcanic rocks that are dominated by vertical to sub-vertically dipping tholeiitic basalt flows. Mineralization is related to fluid movement through the shear system (INAC/GNWT 2010).

Geomorphological conditions at the site are controlled to some degree by a fault system, with the West Bay Fault, creating a steep cliff line along the west side of the property. However, minor structural features, such as fracture sets or shear zones, also have some role and create weaker zones that are followed by local creeks and erosional features.

The major sources of water entering the underground mine include runoff flowing into the open pits, seepage from Baker Creek, seepage from the tailings containment areas, infiltration through soils and bedrock in the mine area, and inflow from groundwater into the underground mine workings. Of the tailings containment areas, the Northwest Pond is the principal source of seepage into the mine. Several of these sources are controlled by climatic conditions, and the total inflow to the mine varies greatly during the year.

The main hydrological feature at the Giant Mine is Baker Creek which originates upstream of the site and generally drains in a southward direction and discharges into Yellowknife Bay. Baker Creek drains in a generally southward direction and discharges into Yellowknife Bay. The catchment area has very low relief and is characterized by a large number of lakes and wetland areas.

The very dry climate of the region also plays an important role in the flows in Baker Creek. The mean annual precipitation of the catchment is approximately 296 mm. The peak flow in 2016 was approximately 0.011 m^3/s. The total catchment area for Baker Creek is estimated at 121 km^2 (WSC 2017). The runoff generated by Baker Creek is only a small fraction of the total precipitation falling on the catchment. The flow in Baker Creek becomes minimal for some period in winter almost every year. Baker Creek can also dry up during the summer, as often as one of every four years.

Groundwater flow follows the generally flat topography eastwards towards Great Slave Lake. The bedrock surrounding the mine has relatively low hydraulic conductivity. Therefore it is expected that groundwater flow likely occurs through joints and fractures rather than the bedrock matrix. The mine is currently dewatered and this activity has lowered the local water table and changed groundwater flows near the mine. Deep groundwater between the lake and the mine is flowing towards the mine workings.

The groundwater flow to the mine is assumed to remain relatively stable throughout the year. The other significant component of base flow to the mine is seepage from the Northwest tailings pond. Infiltration through the ground surface in the local area around the mine enters the mine workings and is therefore captured by the mine dewatering. Once frozen, there will be no vertical or horizontal flow through the chambers. Water from the underground mine areas outside the frozen zones will continue to be pumped and treated as required.

1.4 Summary of Previous Investigations

Since 2010 when the last risk assessment was completed, additional data have been collected for air quality, disturbed and undisturbed soils on the site, fish in Yellowknife Bay, and the aquatic environment in Baker Creek in order to provide more data to support the risk assessment. In 2016, Golder completed a document entitled *Long Term Environmental Monitoring Program Information Consolidation.* This report provided a compilation of existing environmental monitoring reports related to the Giant Mine and its surroundings. The report separated the documents into five chronological periods as follows:

- Phase I: 1948 to mid-1999 when active mining/milling was occurring;
- Phase II: mid-1999 to mid-2004 when Miramar Giant Mine Ltd was on the site;
- Phase III: mid-2004 to early 2008 when the Remedial Plan was prepared;
- Phase IV: early 2008 to 2012 when the Environmental Assessment and Preliminary Design was conducted; and
- Phase V: 2013 to present when the Surface Design Engagement occurred.

There were over 200 reports identified in this compilation, and, as the focus of this risk assessment report was on current and future conditions, documents in the Phase IV and V periods (2011 to 2016) were considered to be representative of the current conditions for risk assessment purposes. Data from other phases were used to infill when it was determined that more current data were not available for some locations. It should be noted that the focus of many of the Phase I to III reports was on arsenic, whereas the Phase IV and V reports provide data for a wider suite of constituents. Appendix A provides a summary of the reports that were considered within the risk assessment.

The available information in these reports was examined to identify where potential data gaps exist for the risk assessment. The locations and pathways identified in the draft HHRA Problem Formulation (Stantec 2015b) were used to guide the data review. Similarly, for the ERA, the locations and pathways of receptors were considered in looking at the available data. Based on the data gaps review, it became apparent that a few gaps needed to be filled for the HHRA and ERA.

For the HHRA, there was a program in place to collect soils and sediments from the Giant Mine Townsite and Shoreline Lands in the summer of 2016. However, as this area is owned by the GNWT, it was determined that the evaluation of the bioaccessibility of the arsenic in the soils and sediments was important to determine the current realistic exposures and help direct remedial activities in this area. Therefore, samples were collected for bioaccessibility. It should be noted that the future land use in this area has not yet been determined.

The Long Lake area has been identified as an area where people camp and swim. The data gaps analysis determined that there was a lack of soil, surface water, and sediment data from this area. Thus, a program to collect soils, sediment and surface water data, as well as some bioaccessibility of the soils and sediments, was initiated in the summer of 2016.

There were limited data available for wild plants (berries, medicinal tea) and wildlife (large game, small mammals, and birds). Thus, a program was initiated with the YKDFN, Metis, and other members of the Yellowknife community to voluntarily collect samples. This program was very successful and a total of 91 samples were collected for use in the HHRA. These samples represented food that people in the community hunted, trapped, gathered, and ate.

Additionally, the amount of different types of food that people ate is available from studies conducted on Dene/Metis communities in 1996 (Receveur et al. 1996) and 1998 (Receveur et al. 1998) by the Centre for Indigenous Peoples' Nutrition and Environment (CINE). These studies were comprehensive studies at the time. However, there have been dietary changes over the last 20 years, mainly pertaining to the ban on caribou hunting. Thus, other wild game has been used as a substitute for the lack of caribou meat in the YKDFN diet. The YKDFN identified the need for an updated dietary survey. A dietary survey was conducted in the YKDFN and Metis communities to update the data collected by the CINE studies.

From an ERA perspective, there was not a lot of information on the chemistry of the terrestrial or aquatic vegetation present at the Giant Mine. Thus, a sampling program was initiated in the summer of 2016 to collect vegetation species that represent browse and forage from both disturbed and undisturbed areas of the Giant Mine to determine whether differences exist in the uptake of COPC from both these areas. Co-located soils samples were collected so that transfer factors could be developed to describe future conditions in the risk assessment. In addition, bioaccessibility of arsenic in the plant species was also undertaken.

Another area of uncertainty in risk assessments surrounds the use of transfer factors to determine concentrations of COPC in prey. In order to reduce this uncertainty and data gap, a program to collect small mammals (mice/voles) from both the disturbed and undisturbed areas of the Giant Mine was initiated. The data from these mice/voles would serve as a surrogate for other small mammals at the site and would also reflect the uptake of arsenic from plants.

1.5 Remediation Actions

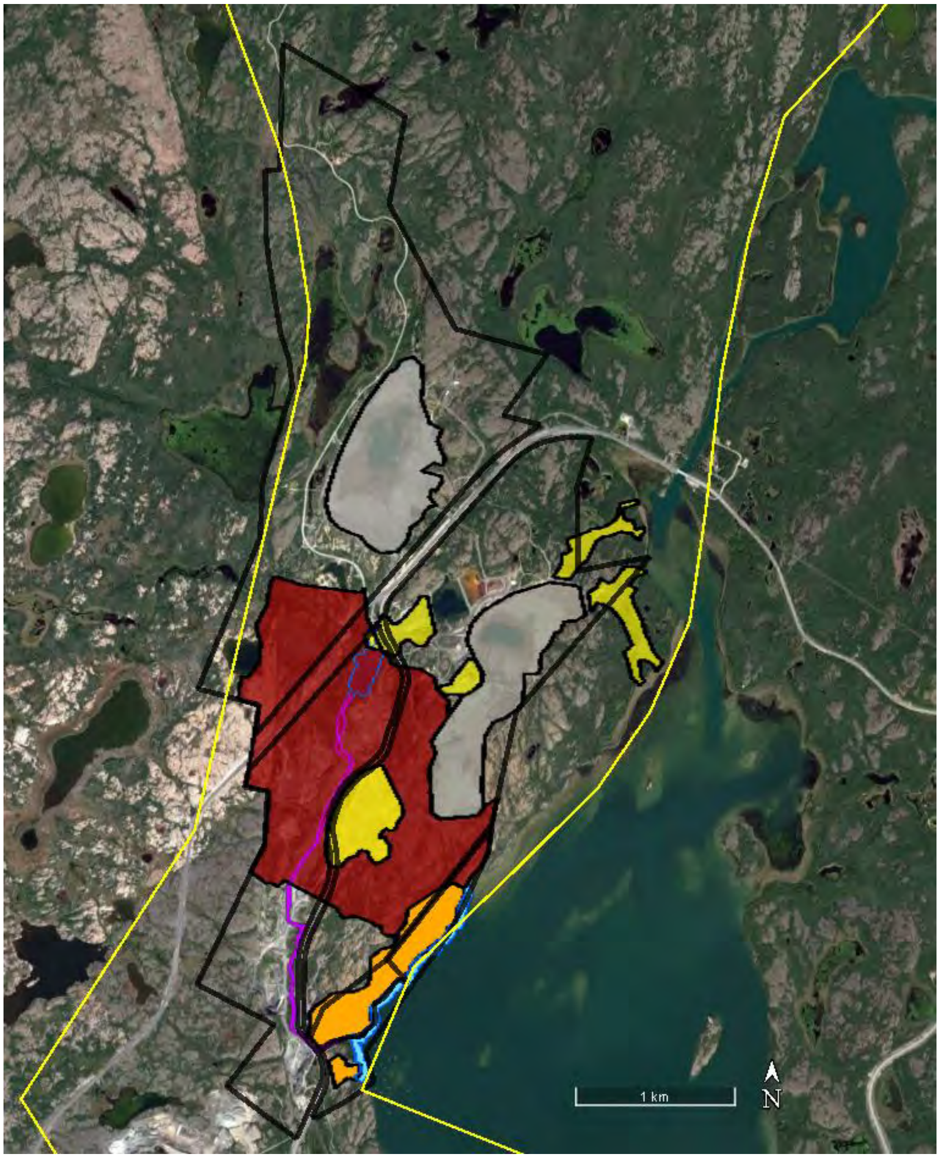
As part of the GMRP, several remedial activities have occurred on site. Numerous buildings have been demolished and the mill and headframe have been taken down.

A high level overview of the Giant Mine Remediation is as follows:

- Arsenic trioxide in the sealed underground chambers and vaults will be frozen *in situ*, in artificial permafrost.
- Surface conditions at the Giant Mine will be remediated. This includes the capping of the four tailings ponds, filling in the 8 open pits, remediating contaminated soils in the disturbed areas of the site to GNWT industrial land use soil criteria, and active management or areas with arsenic concentrations greater than 3000 mg/kg in the form of excavation and/or fencing.
- Water will continue to be treated on site and the outfall of the treatment plant will be relocated from Baker Creek to a location in the vicinity of Reach 0 in Yellowknife Bay. Water will be treated to the Canadian Drinking Water Guideline of 10 µg/L and will meet Site Specific Water Quality Objectives to prevent significant adverse impacts to Great Slave Lake as required by Measure 12 (MVEIRB).
- The sediments in Reach 1 to 6 in Baker Creek will be dredged and Baker Pond will be capped and investigated further as potential wetland.
- The soils in the former Townsite will be remediated to GNWT residential criteria and the sediments in the near shore will be dredged and covered.
- Ongoing monitoring will continue indefinitely at the Giant Mine after remediation is completed.

Figure 1.4 shows a schematic of the areas that will undergo remediation and active management at the Giant Mine.

Figure 1.4 Schematic of remediation activities for soils at Giant Mine



Note: Thick black line around coloured areas represent the lease boundary. Yellow lines denote the Yellowknife Greenstone Belt.
Yellow areas inside the lease boundary represent the disturbed areas to be remediated to GNWT industrial criteria for arsenic.
Red area represents area where the arsenic in soils exceeds 3000mg/kg.
Grey areas represent tailings ponds.
Orange areas at bottom of map represent the former Townsite and marina; these areas will be remediated to GNWT residential criteria.
Yellow areas outside boundary of East Baker creek are the tailings spills.
Baker creek (shown in purple), Baker Pond (outlined in blue), and the near-shore Townsite sediments (shown in light blue) are areas identified for sediment remediation.

1.6 Stakeholder Involvement

There has been stakeholder involvement throughout the current risk assessment process through involvement with the Giant Mine Working Group (WG). The WG is made up of members from INAC, GNWT, Public Services and Procurement Canada (PSPC), Environment and Climate Change Canada (ECCC), Department of Fisheries and Oceans (DFO), Alternatives North, YKDFN, North Slave Metis Alliance (NSMA), City of Yellowknife, Health Canada, Giant Mine Oversight Body, and Bill Slater, who is a consultant to the WG.

The preliminary problem formulation for the HHRA (Stantec 2015b) was prepared in consultation with the working group. The CanNorth study team has had five meetings with the WG to present data gaps, problem formulation, methodologies for the assessment as well as the dietary survey, the results of the dietary survey, and other aspects of the risk assessment.

The study team has also had meetings with the YKDFN Giant Mine Advisory Committee (GMAC) to discuss aspects of the risk assessment and to solicit their input in terms of different foods eaten in the community, locations where foods are hunted, trapped, and gathered, and what their concerns were. GMAC was also consulted on the voluntary sampling program, and YKDFN staff and Canada North Environmental Services (CanNorth) went into the YKDFN community to collect samples from various households. Members of the NSMA also provided samples to be analyzed as part of the voluntary sampling program.

Members from the YKDFN and NSMA also participated in the update to the dietary survey and provided valuable information that was used in the risk assessment.

1.7 Scope of Risk Assessment

For the current scenario, the HHRA considers risks from exposure to arsenic and other COPC to members of the public in Ndilo, Dettah, Latham Island, Ingraham Trail, and the City of Yellowknife. For the future scenario, the risk assessment considers the risk due to contamination at the Giant Mine that a person would likely experience after remedial activities at the site have been implemented.

A multi-media approach was taken that considered exposure from all relevant environmental components such as air, dust, soil, sediment, water, and country foods.

This risk assessment was conducted as a detailed Deterministic Quantitative Risk Assessment (DQRA), since it relied on a substantial database of available monitoring data, as well as anecdotal information regarding where hunting, trapping, and gathering occur in the vicinity of the Giant Mine and the potential future use of the Giant Mine after remedial activities have occurred. The risk assessment followed guidance outlined by Health Canada (Health Canada 2010a).

For the future scenario, the remedial actions associated with clean up of the disturbed areas on the Giant Mine to GNWT industrial criteria were used to determine what the future conditions at the Giant Mine would be. In addition, the remedial plans include active management in terms or excavation and/or fencing of an area where the arsenic concentrations are above 3000 mg/kg. Consultation with stakeholders on the future use of the Giant Mine indicated that members of the YKDFN did not want to use the site in the future; however other stakeholders indicated that they would like to use the Giant Mine in the future. Therefore, the future scenario considered recreational use of the Giant Mine outside of these areas and a potential for residential use at the former Townsite. It is acknowledged that the future land use has not been determined for the Townsite; however, a residential scenario represents the most restrictive land use in this area.

The ERA was a deterministic Preliminary Quantitative Risk Assessment (PQRA) for exposure at the Giant Mine and was an update of the previous assessment carried out at the Giant Mine in 2006 (SENES 2006). The risk assessment followed guidance outlined by Environment Canada from their Federal Contaminated Sites Action Plan (FCSAP) Ecological Risk Assessment guidance document (FCSAP 2012a). The Giant Mine was divided into four areas or quadrants in order to focus the evaluation in the areas where remediation was occurring. A number of different ecological receptors were selected ranging from small animals that have small home ranges, such as mice, to larger animals that could roam across the Giant Mine, such as a lynx or a fox. Very large animals such as moose, caribou, and bear were not considered as the Giant Mine only occupies a very small area where they roam, and previous assessments indicated that they were not at risk. Fish, aquatic plants, and small animals (muskrat, mink) that are present in the water and sediment of Baker Creek were also considered.

For the future scenario, a simple fate and transport model was used to determine what the water and sediment concentrations in Baker Creek and Yellowknife Bay would be post remediation. This model used information from other studies, such as arsenic loadings from Golder (2016b), as input to the model. For the Giant Mine, the remedial actions associated with clean up of the disturbed areas to GNWT industrial criteria were used to determine the future conditions at the Giant Mine. There is the potential for changes in the environment in the future due to climate change. In general, the long-term meteorological data set for Yellowknife shows trends toward milder temperatures and more precipitation (INAC/GNWT 2010). There are a number of consequences of climate change, including greater precipitation and evaporation, the potential for more site runoff, water quality changes due to increased algae growth, changes to the vegetation in the area due to warmer temperatures and a longer growing season, presence of different wildlife, and changes to people's diet due to the presence of different species. Determining the effects of climate change on ecological and human health is complicated and is addressed in a qualitative manner in the risk assessment.

2.0 SITE CHARACTERIZATION

2.1 Review of Existing Site Information

The GMRP has conducted numerous studies at the Giant Mine in order to understand the conditions of the soils, sediments, and surface water on and around the site. These studies were all considered in the risk assessment, as well as in the development of the remedial action plans for the Giant Mine.

The GMRP does not conduct much sampling outside of the Giant Mine and, therefore, off-site sampling programs have been conducted as studies for the Cumulative Impact Monitoring Program (CIMP), the YKDFN, or the GNWT. The historic soil samples focused on arsenic, whereas the current programs analyzed a wider suite of COPC.

A summary of available data for each of the media considered in the human health and ecological risk assessment is presented below along with maps of the sampling locations. A full data set of all the samples that were considered in the HHERA is provided in Appendix O.

2.1.1 Air

Ambient air quality is monitored year-round under the Giant Mine Ambient Air Monitoring Program at the following community locations:

- Marina Station – Great Slave Sailing Club, near the Giant Mine public dock (Station YCC).
- Ndilo Station – Central Ndilo (Station NDL).
- Yellowknife Station – Downtown Yellowknife City (Station NAPS).

Additional atmospheric monitoring programs record conditions at six fenceline stations, as well as at a number of stations on the Giant Mine property.

Air quality data collected over the 2015 calendar year at the community, fenceline, and Giant Mine stations were used to represent current conditions. Sample locations are presented in Figure 2.1 and a summary of the data is presented in Appendix B. These data were used to evaluate the current conditions at the Giant Mine. In the future after the site has been cleaned up there will be no releases from the Giant Mine and air quality is assumed to be similar to baseline.

Figure 2.1 Air sampling locations around Giant Mine

2.1.2 Soil

2.1.2.1 Giant Mine

There have been a number of soil studies carried out at the Giant Mine that have focussed on the disturbed and undisturbed soils, and there were over 300 recent soil samples collected at the Giant Mine. The following studies were included in the characterization of Giant Mine soils:

- *AECOM (2016) Contaminated soils Task 2C: North Tailings Pond - historical tailings release preliminary results for 2016 field investigation. Memorandum to D. Hango, Public Services and Procurement Canada, October 7th, 2016.*

- *Contango (2016) Wetland field investigation report for Giant Mine. Document # 003_1116_04A. Prepared for Golder Associates, November.*

- *ESG (2001a) Arsenic levels in the Yellowknife Area: Distinguishing between natural and anthropogenic inputs.*

- *Golder (2014) Revised letter report on shallow soil sampling programs Giant Mine, Yellowknife, NWT. Project No. 13-1377-0147, February.*

- *Golder (2015a) Arsenic Characterization Disturbed Areas Giant Mine, Yellowknife, NWT.*

- *Golder (2016c) Arsenic Characterization Disturbed Areas Giant Mine, Yellowknife, NWT.*

- *Golder (2016d) Draft report on arsenic characterization undisturbed areas Giant Mine, Yellowknife, NWT.*

- *Golder (2016e) Task 2A - potential remedial strategy Town Site and shoreline lands, Giant Mine project, NWT. Report number 13-1377-0044, submitted to Public Works and Government Services Canada. Draft report, September.*

- *Golder (2016f) Preliminary findings memo - Task 2B: Development of institutional/engineering control strategy proposed core industrial area, Giant Mine project, NWT. Technical memorandum to D. Hango, Public Services and Procurement Canada, October 7th, 2016.*

- *Golder (2016g) Giant Mine data report - human health and ecological risk assessment data gaps.*

- *Golder (2016h) Roaster Complex soil and vegetation sampling Giant Mine, Yellowknife, NWT.*

- *Kerr (2001) Till geochemistry, Yellowknife area, NWT. Natural Resources Canada, Ottawa. http://geochem.nrcan.gc.ca/cdogs/content/svy/svy210026_e.htm.*

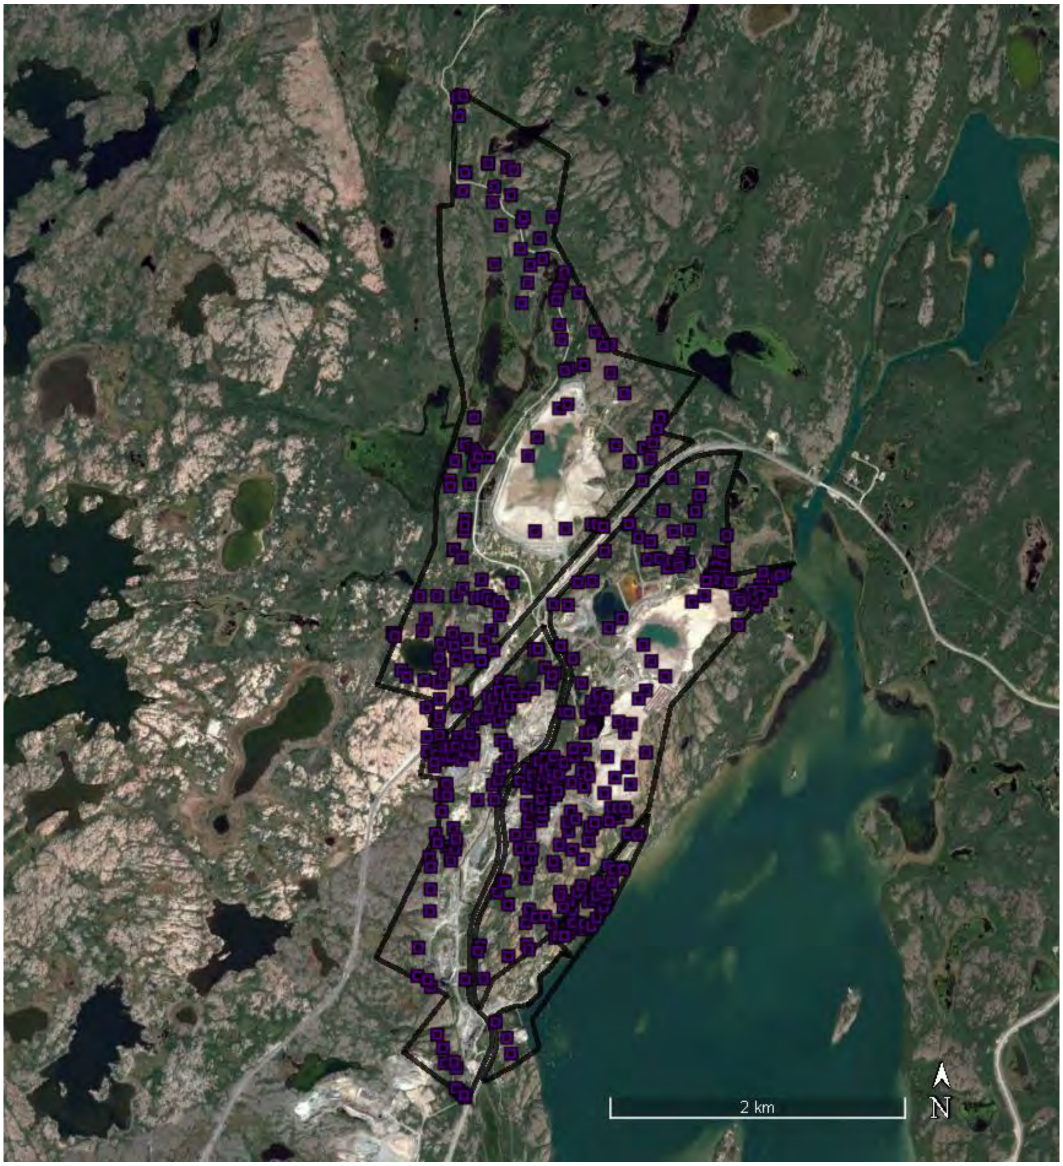
- *Stantec (2014b) Analysis of contaminants in tissues of fish captured in the Yellowknife Bay area, NWT. Task authorization 700263428, prepared for Public Works and Government Services Canada. Final report, March.*

- *Bromstad, M.J. (2011) The characterization, persistence and bioaccessibility of roaster-derived arsenic in surface soils at Giant Mine, Yellowknife, NWT. Master of Science thesis, Department of Geological Sciences and Geological Engineering, Queen's University.*

- *Wrye, L.A. (2008) Distinguishing between natural and anthropogenic sources of arsenic in soils from the Giant Mine, NWT, and the North Brookfield Mine, Nova Scotia. Queen's University.*

Sample locations are presented in Figure 2.2. As seen in the figure, there are an adequate number of samples to characterize soils at the Giant Mine. Appendix B provides a summary of the soil quality data for the Giant Mine.

Figure 2.2 Soil sampling locations on the Giant Mine



2.1.2.2 Former Townsite

There have been four studies with soil data at the former Townsite (Wrye 2008; Golder 2015a, 2016e, 2016g). More than 90 soil samples were available and were considered to be adequate to characterize exposure at the former Townsite. Sample locations are presented in Figure 2.3 and Appendix B provides a summary of the soil quality data for the former Townsite.

Figure 2.3 Soil sampling locations on the former Giant Townsite

2.1.2.3 City of Yellowknife

There have been six studies containing soil data for the City of Yellowknife (ESG 2000; Kerr 2001; NCP 1999; Ollson 2000; Obst 2014; SENES 2006). The majority of samples were collected at surficial soil depths and were sufficient for characterizing City of Yellowknife soils. Sample locations are presented in Figure 2.4. The sample locations only represent locations where co-ordinates are available. It should be noted that there are over 250 arsenic soil samples associated with the City of Yellowknife that are considered to be adequate to characterize exposure in the City of Yellowknife. Appendix B provides a summary of the soil quality data for the City of Yellowknife.

Figure 2.4 Soil sampling locations for the City of Yellowknife

2.1.2.4 Ndilo

For the community of Ndilo, one study contains soil sampling data in the upper 10 cm of soil:

- *RMCC (2013) Arsenic in Ndilo, NT: 2012 sampling (contains data from 2012).*

There are 25 surficial samples from this study. The RMCC (2013) dataset also included eight samples from the Environmental Sciences Group (ESG 2000) and 14 from SENES (2006).

Another study conducted in 2014 by Stantec collected 90 samples across Ndilo at depths ranging from 10 cm to 30 cm to represent tilled material:

- *Deton' Cho Stantec (2014) Characterization of arsenic concentrations in soils in Ndilo, NWT.*

It should be noted that only surficial soil samples from the first 10 cm were used to characterize soils in Ndilo. Soils deeper than 10 cm were not included in the dataset and thus the 2014 Stantec data were not used in the risk assessment as the arsenic concentrations were lower than the surface samples. Sample locations are presented in Figure 2.5, and it can be seen that exposure in Ndilo can be adequately characterized by these samples. Appendix B provides a summary of the soil quality data for Ndilo.

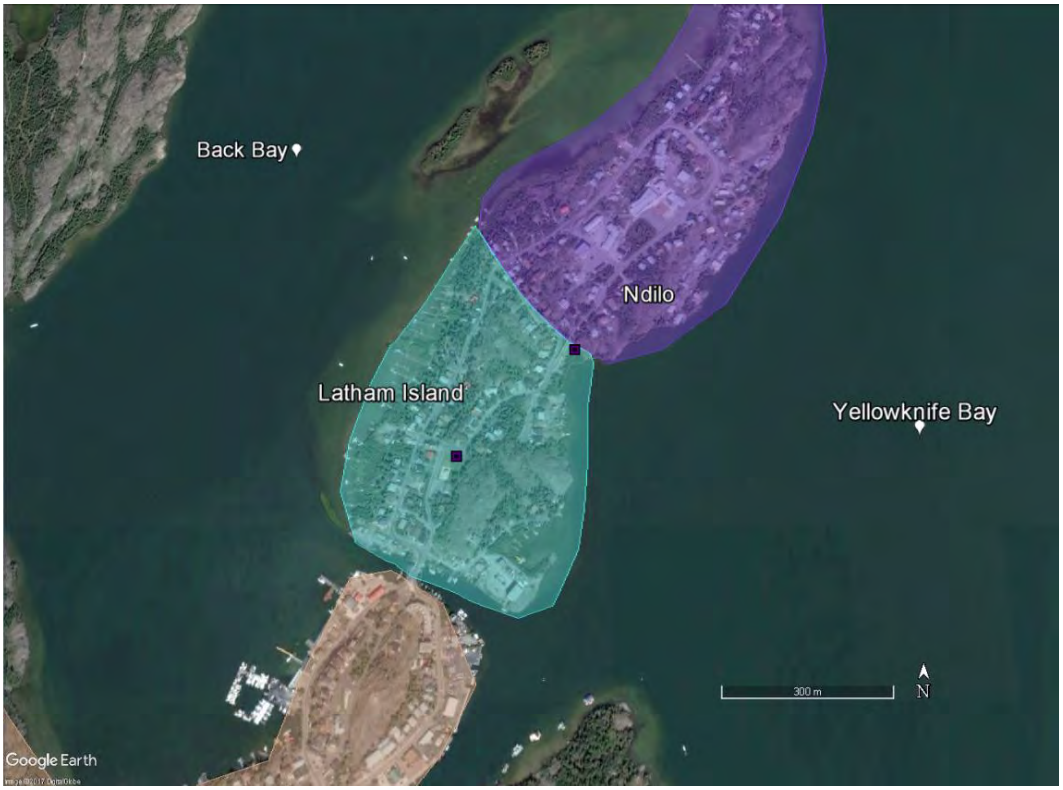
Figure 2.5 Soil sampling locations for Ndilo

2.1.2.5 Latham Island

There have been very little data collected in the community on Latham Island with only two samples available for most constituents. There were four studies that contained information on soil sampling (NCP 1999; ESG 2000; Ollson 2000; SENES 2006). Figure 2.6 shows the two sample locations on Latham Island. Due to the proximity to

Ndilo, the two datasets were combined to describe the exposure from soils at Latham Island. Appendix B provides a summary of the soil quality data for Latham Island.

Figure 2.6 Soil sampling locations for Latham Island



2.1.2.6 Ingraham Trail

There have been very little data collected in the community on Ingraham Trail. There were three studies that contained information on soil sampling (ESG 2001a; Kerr 2000; Obst 2014). All samples were obtained at surficial depths. There are 12 samples for arsenic and this is the main COPC identified. Sample locations are presented in Figure 2.7. These are the only data available and, therefore, were used in the assessment. Appendix B provides a summary of the soil quality data for Ingraham Trail. Additional samples were collected along the Ingraham Trail as part of the work done by Queens University (Jamieson et al. 2017) and the data are presented in Appendix P. This study resulted in an additional 16 samples being available for arsenic.

Figure 2.7 Soil sampling locations for Ingraham Trail

2.1.2.7 Fred Henne Campground

The Fred Henne Campground was identified as an area of concern for people from Yellowknife who go there to camp. This was recognized as a data gap, and 11 samples were collected in 2016 by Golder (2016g) to support the data gaps analysis. An additional sample from Ollson (2000) was also used to characterize soils. The samples were collected from areas where people were known to use tents. Sample locations are presented on Figure 2.8. Five samples were also sent for arsenic bioaccessibility testing. Appendix B provides a summary of the soil quality data for the Fred Henne Campground.

Figure 2.8 Soil sampling locations for Fred Henne Campground

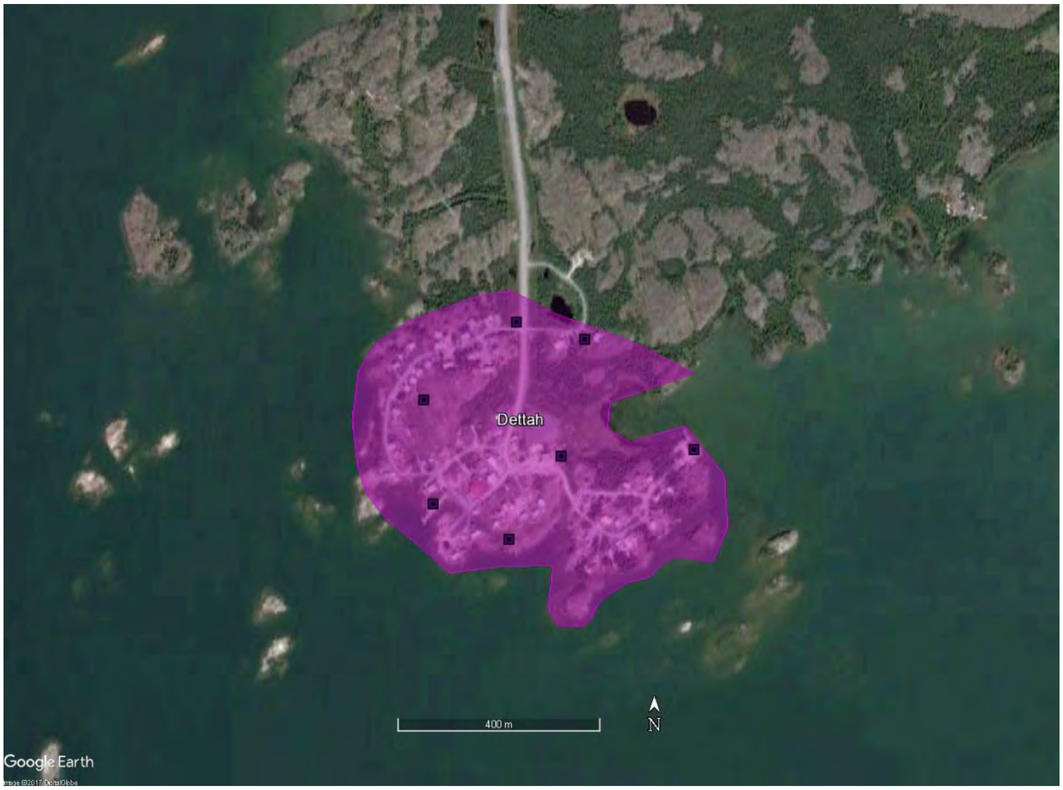
2.1.2.8 Dettah

There have been very little data collected in the community of Dettah. There were two studies that contained soil sampling:

- *ESG (2000) Arsenic Levels in the Yellowknife Area: Distinguishing Between Natural and Anthropogenic Inputs.*
- *NCP (1999) Risk Characterization of Arsenic Exposure to Berries in Akaitcho Territory.*

Sample locations are presented in Figure 2.9. These are the only data available and, as such, they were used in the assessment. It is acknowledged that adequate coverage has not been provided in Dettah, but these are the only samples available to be used in the risk assessment. Limited additional samples were collected in and around as part of the work done by Queens University (Jamieson et al. 2017) and the data are presented in Appendix P. This study resulted in two additional soil samples.

Figure 2.9 Soil sampling locations for Dettah



2.1.3 Surface Water

Surface water samples are available from various areas around Yellowknife Bay, Baker Creek, the Upper Baker Creek Watershed, and background locations not directly influenced by mining operations.

2.1.3.1 Baker Creek

There are a large amount of samples available for Baker Creek (more than 300 samples) from all the studies that have been completed on Baker Creek. The samples were obtained from several studies collected from 2011 through 2016 (Golder 2013a, 2013b, 2015a, 2015b; Stantec 2014a, 2014b; DCNJV 2015; Contango 2016). Sample locations are presented in Figure 2.10. Appendix B provides a summary of the water quality data for Baker Creek. There are enough surface water samples to adequately characterize Baker Creek.

Figure 2.10 Surface water sampling locations in Baker Creek

2.1.3.2 Yellowknife Bay

Yellowknife Bay was broken into three areas: Back Bay, which receives inputs from Baker Creek; North Yellowknife Bay, which interacts with Back Bay; and South Yellowknife Bay. The various areas of Yellowknife Bay (Back Bay, North Yellowknife Bay, and South Yellowknife Bay) have been well characterized, with more than 150 samples collected in recent years (2012 through 2016). Surface water samples were obtained from five studies (Golder 2012; Stantec 2014c; Palmer 2016a; Contango 2016; Chételat 2016, 2015). Sample locations are presented in Figure 2.11. There are enough surface water samples to adequately characterize the various areas of Yellowknife Bay. Appendix B provides a summary of the water quality data for Yellowknife Bay.

Figure 2.11 Surface water sampling locations from Yellowknife Bay

2.1.3.3 Municipal Drinking Water

Municipal drinking water data was provided to the study team by the City of Yellowknife from years 2002 until 2016. Appendix B provides a summary of the data.

2.1.4 Sediment

There have been a number of sediment studies carried out in Yellowknife Bay and in Baker Creek. For the purposes of the HHRA, sediments close to the shore were the focus, since people could be exposed to COPC while wading along the shoreline. For the ERA, shoreline sediments and sediments found at deeper depths were considered. Only sediment data in the top 10 cm were considered, as it is unlikely that benthic invertebrates would colonize the deeper sediments and people would only be exposed to the surficial sediments.

2.1.4.1 Baker Creek

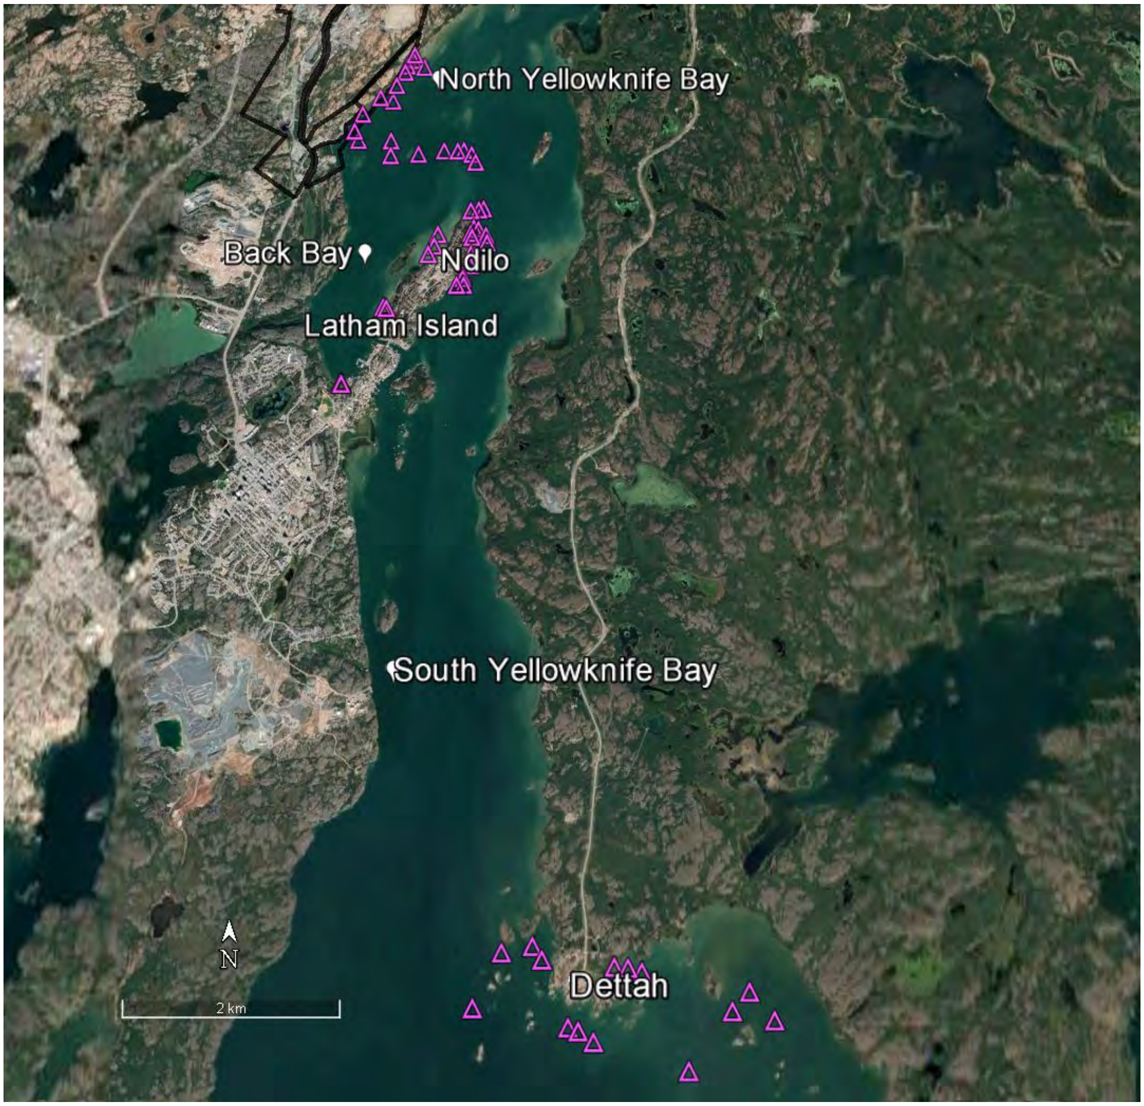
A total of 11 sediment sampling programs were available to characterize Baker Creek sediment (Jacques Whitford 2006; Stantec 2012, 2014a, 2015; Golder 2013a, 2013b, 2015b, 2016b, 2016e, 2017; Galloway et al. 2015). There were more than three hundred sediment samples collected across Baker Creek. Therefore, the creek is considered to be adequately characterized. Sample locations are presented in Figure 2.12 and Appendix B provides a summary of the sediment quality data for Baker Creek.

Figure 2.12 Sediment sampling locations from Baker Creek

2.1.4.2 Yellowknife Bay

Yellowknife Bay was broken down into three areas: Back Bay, which receives inputs from Baker Creek; North Yellowknife Bay, which interacts with Back Bay; and South Yellowknife Bay. The various areas of Yellowknife Bay (Back Bay, North Yellowknife Bay, and South Yellowknife Bay) have been well characterized, with more than 150 samples collected in recent years (2004 through 2016). A total of five sediment sampling programs were available to characterize Yellowknife Bay sediments (ECCC 2015a, 2015b; Golder 2016g; Palmer 2016b; Stantec 2014c). The majority of samples (approximately 150) were collected in surface samples (top 10 cm). Sample locations are presented in Figure 2.13. From a human health perspective, sediments close to the shoreline at Ndilo and Dettah were used to characterize exposure for a wading scenario. Additionally, Mike Palmer from GNWT collected some sediment samples in Back Bay, where concerns were raised about children wading in the areas near docks. There were about 20 sediment samples in Yellowknife Bay that were used to characterize sediments close to the shoreline. Over 60 sediment samples were used to characterize exposure in Yellowknife Bay from an ecological perspective. Appendix B provides a summary of the sediment quality data for Yellowknife Bay.

Figure 2.13 Sediment sampling locations from Yellowknife Bay



2.1.4.3 Long Lake

There were also concerns raised about children wading and playing in the shallow sediments in Long Lake. This was identified as a data gap and was addressed by sampling conducted by Golder (2016g). Sediment samples were collected from the beach area, day use area, and from the boat launch. Figure 2.14 shows the locations of the sediment samples, and Appendix B provides a summary of the sediment quality data.

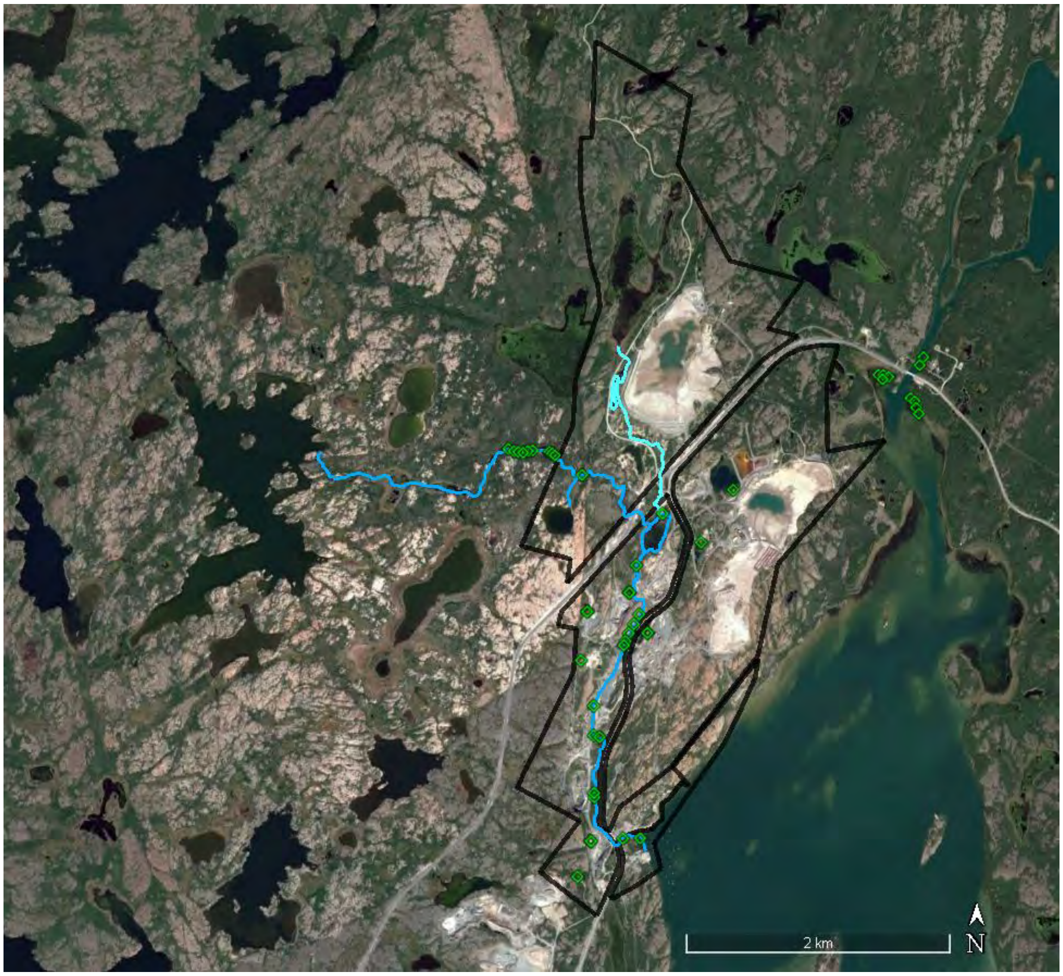
Figure 2.14 Sediment sampling locations from Long Lake

2.1.5 Vegetation

2.1.5.1 Aquatic Plants

Two recent aquatic plant sampling programs were conducted on the Giant Mine (Contango 2016; Golder 2016g). More than 30 samples of cattails and various species of sedges were collected for analysis to represent aquatic plants on the Giant Mine. There were 22 samples collected as part of the data gaps analysis gap filling study, since it was determined that there was not an adequate database available. Sample locations are presented in Figure 2.15. These samples were considered to be adequate for use in the risk assessment. Appendix B provides a summary of the aquatic plant data at the Giant Mine.

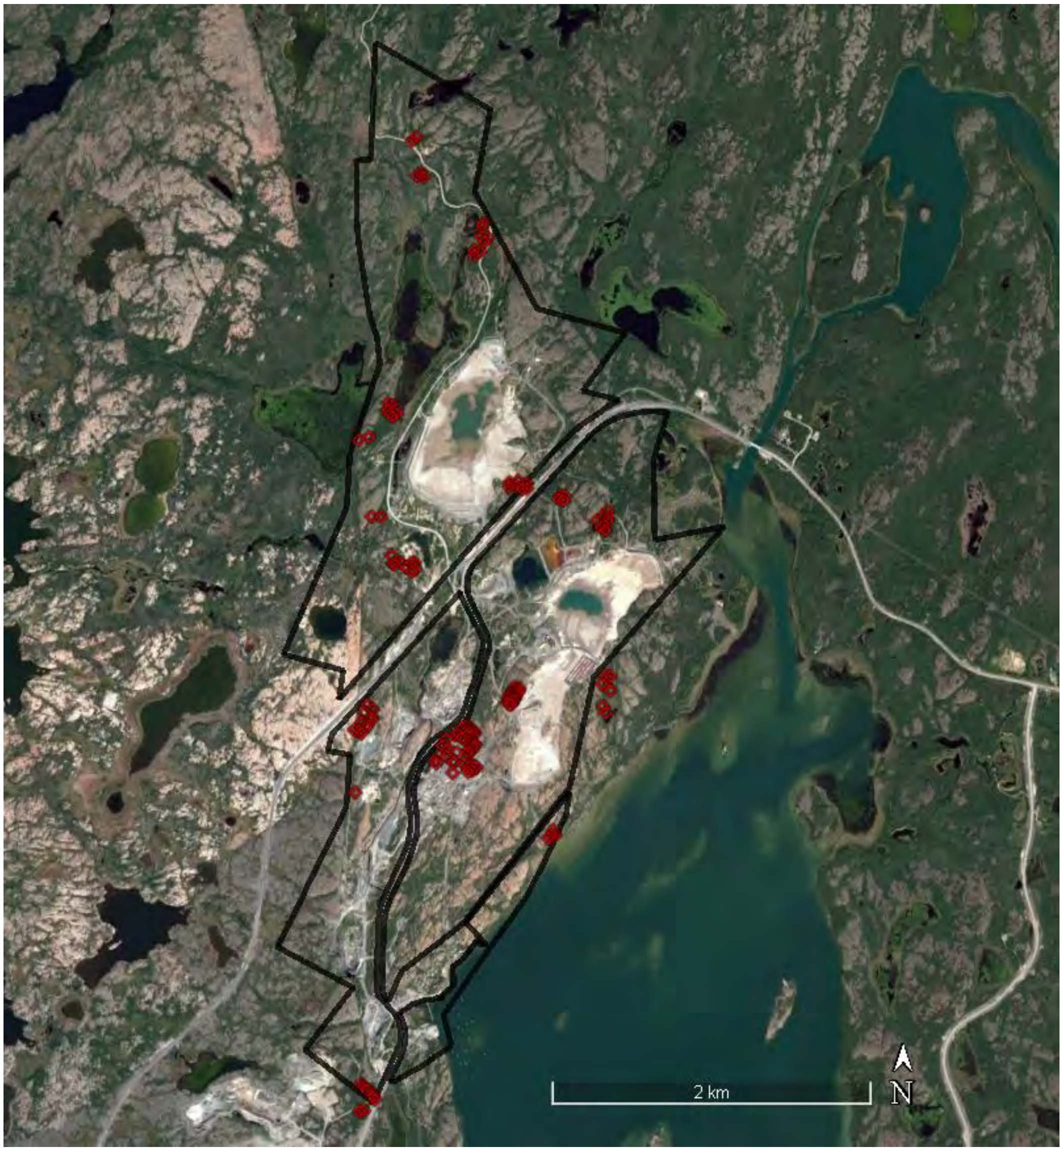
Figure 2.15 Aquatic plant sampling locations from Giant Mine



2.1.5.2 Terrestrial Plants

Four terrestrial wild plant sampling programs were conducted on the Giant Mine with more than 90 samples collected (Contango 2016; Golder 2016h, 2016g; Stantec 2014b). Foliage, fruits and flowers, lichen and moss, and woody vegetation samples were collected for analysis to represent terrestrial wild plants on the Giant Mine. Of the samples used to characterize the terrestrial plants on the Giant Mine, 87 were obtained as a part of the Golder (2016g) Giant Mine data gap filling report. Sample locations are presented in Figure 2.16. It was determined that these samples are adequate for use in the risk assessment. Appendix B provides a summary of the terrestrial plant data at the Giant Mine.

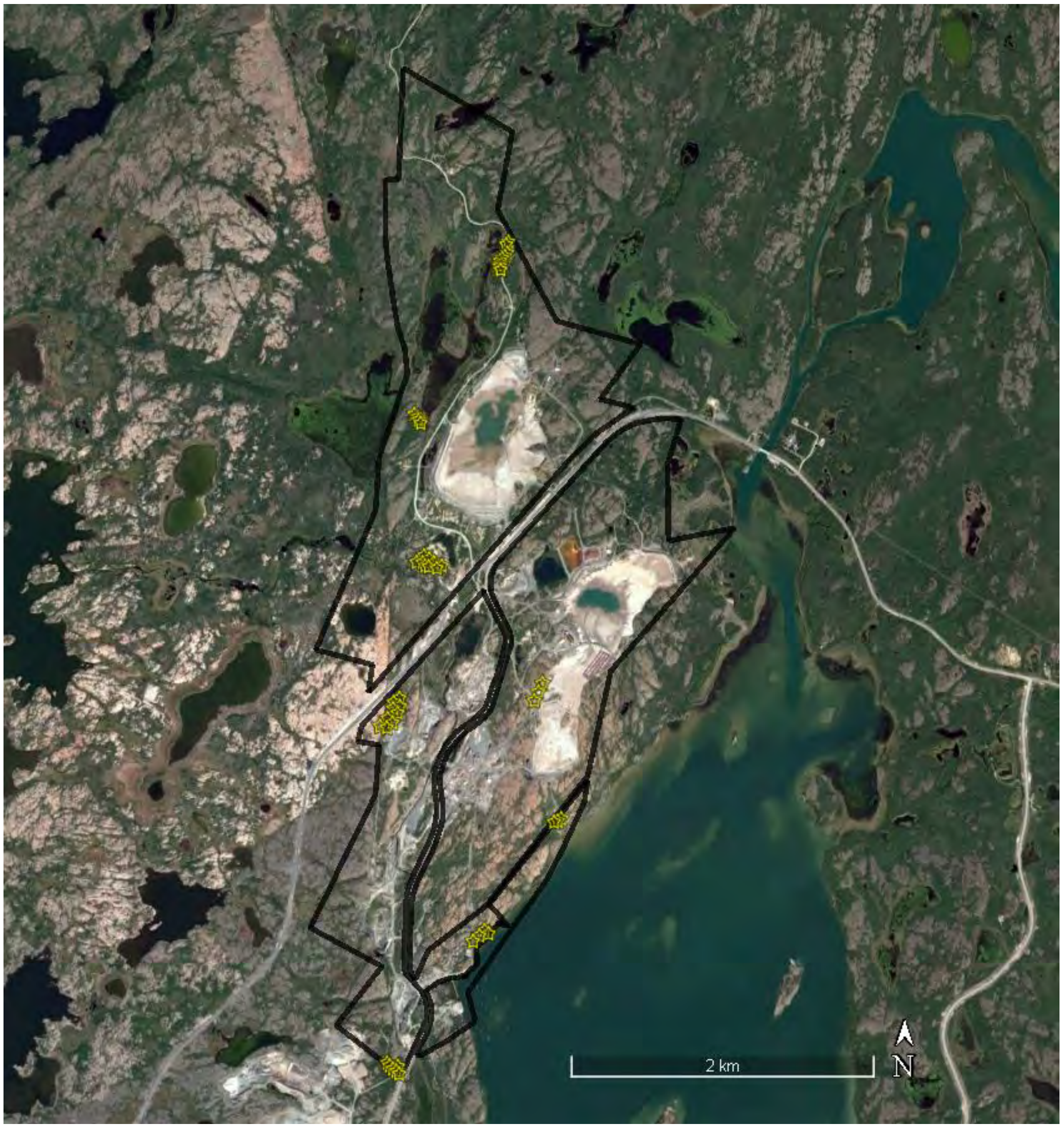
Figure 2.16 Terrestrial plant sampling locations from Giant Mine



2.1.6 Animals

The data gaps exercise identified that there was a lack of small mammal data at the Giant Mine. Therefore, Golder (2016g) undertook a program to characterize terrestrial small mammals on the Giant Mine and former Townsite (see Appendix B). A total of 50 northern red backed vole, deer mice, or shrew samples were obtained for analysis. Sample locations are presented in Figure 2.17. It was determined that these samples were adequate for use in the risk assessment. Appendix B provides a summary of the small mammal data.

Figure 2.17 Small mammal sampling locations from Giant Mine and former Townsite



2.1.7 Fish

There have been several fish studies carried out in Baker Creek and Yellowknife Bay since 2011 that were considered appropriate for consideration within the risk assessment. In examining the fish data, there are different requirements from both a human health and ecological perspective. For human health, fish tissue that is consumed by people was the focus of the summaries. Discussions with the YKDFN community indicated that they consume trout, lake whitefish, and inconnu.

2.1.7.1 Whole Body Fish from Baker Creek

Two studies contained data on whole body fish in Baker Creek (Golder 2013a; Stantec 2014d). All samples were obtained from lower Baker Creek (Reach 0 and Reach 1), with 36 samples of slimy sculpin, 9 spine stickleback, and arctic grayling obtained for analysis for most constituents. Appendix B provides a summary of whole body fish data in Baker Creek. Mapping has not been provided of these samples, as all of the samples were obtained from Reach 0 and 1 in Baker Creek. These samples were considered in the ERA.

2.1.7.2 Whole Body Fish from Yellowknife Bay

One sampling program contained data on whole body fish in Yellowknife Bay (Stantec 2014d). A total of 61 samples of slimy sculpin were obtained from North Yellowknife Bay and South Yellowknife Bay near the City of Yellowknife. These samples were considered in the ERA.

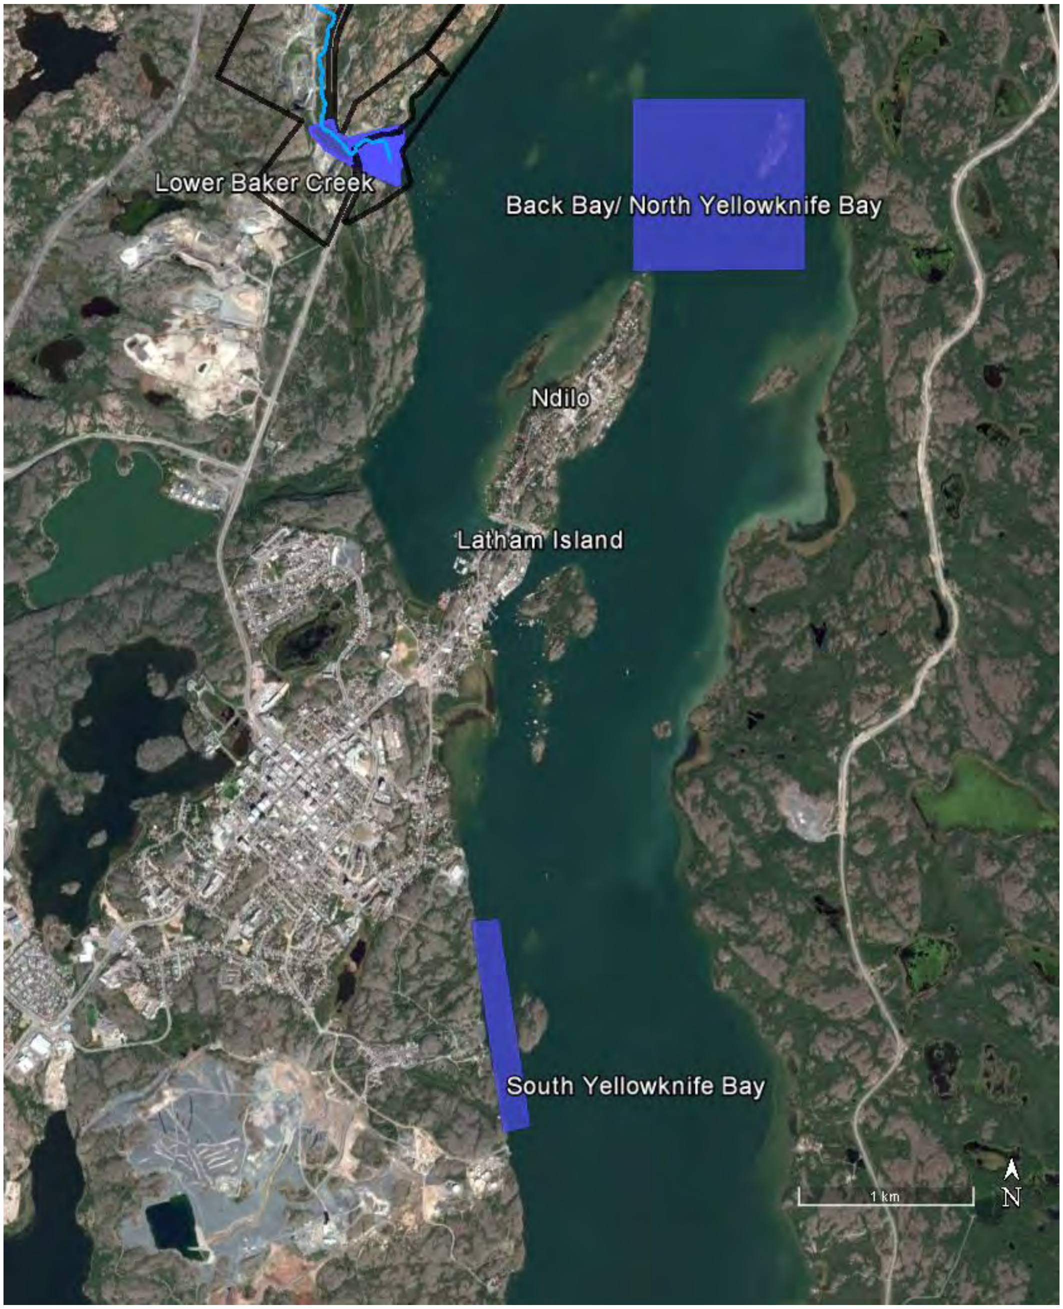
2.1.7.3 Fish Muscle from Yellowknife Bay

Two sampling programs contained information on fish muscle in Yellowknife Bay, which included samples from Back Bay, North Yellowknife Bay, and South Yellowknife Bay (Cott et al. 2016; Stantec 2014d). Samples of burbot, inconnu, lake trout, lake whitefish, and northern pike muscle were analysed for most constituents.

2.1.7.4 Fish Liver from Yellowknife Bay

Two sampling programs were identified to characterize fish liver in Yellowknife Bay, which included samples from Back Bay, North Yellowknife Bay, and South Yellowknife Bay (Cott et al. 2016; Stantec 2014d). Samples of lake whitefish and northern pike livers were obtained for analysis for most constituents.

Figure 2.18 Fish sampling locations from Baker Creek and Yellowknife Bay



2.1.8 Voluntary Sampling Program

As part of the risk assessment, a voluntary sampling program was initiated to collect samples of country foods that members of the different communities would eat. Members of the YKDFN, NSMA, and other interested stakeholders were asked to submit samples of country foods to the GMRP study team. The community was asked to provide large wild game (moose) samples, small game samples from different types of animals (i.e., rabbit, beaver, muskrat) and birds (i.e., grouse, ptarmigan, duck, goose), berry or edible plant samples, and medicinal plant samples. Organ samples were also requested. There was a large number of fish samples from different areas in Yellowknife Bay that were collected by various scientific programs; however, no lake trout samples were collected as part of these programs and, thus, community members were asked to provide lake trout samples if they had any. The samples provided by various community members were then sent to the laboratory for analyses.

This voluntary sampling program was not meant to be a rigorous statistically based study; rather, it was an attempt to collect country food samples that people were gathering and eating so that their current exposures could be quantified. Risk assessment programs generally do not have this information and instead use estimates based on calculations involving estimates of transfer of chemicals in the environment. Thus, the voluntary sampling program was a way of reducing this uncertainty in the risk assessment.

Figure 2.19 to Figure 2.23 show the approximate locations where the voluntary samples of country foods were obtained. Approximately 88 samples were submitted to the laboratory for analysis. The number of samples collected in this program was exceptional and has never been collected in any risk assessment project in Canada to the best of our knowledge. Table 2.1 provides a summary of the samples that were sent for analysis.

Table 2.1 Summary of country foods sent for laboratory analysis

Sample Type	Sample Species (Number of Samples Submitted)		Tissues Sampled
Plants	• Cranberries (11) • Labrador tea (4) • Raspberries (4) • Rose hips (3) • Red bear berries (1)	• Juniper berries (2) • Spruce gum (4) • Saskatoon berries (1) • Chives (1) • Birch syrup (1)	Berries, gum, syrup, tea
Fungi	• Mushroom (1)		
Birds	• White winged scoter (3) • Canada goose (1) • Ptarmigan (12)	• Black ducks (5) • Mallard ducks (2) • Spruce grouse (6) • Lesser scaup (1)	Flesh, Fat, Gizzard, Liver, Heart
Mammals	• Moose (10) • Muskox (1) • Muskrat (2) • Rabbit (2)	• Bear (1) • Beaver (4) • Caribou (1) • Reindeer (1) [a]	Flesh, Liver, Heart, Fat
Fish	• Lake trout (5)	• Whitefish (4)	Flesh, Eggs

Note: [a] reindeer sample from Inuvik which is greater than 200 km away

As can be seen in Figure 2.19, around half (43) of the samples collected were from within 10 km of the Giant Mine. Table 2.2 provides a summary of the samples and quite a few of the berries and other plants were collected from Ndilo (see Figure 2.20). Twenty four (24) of the samples were collected from between 10 km and 25 km of the Giant Mine (see Figure 2.21 and Table 2.3), 10 samples were obtained between 25 km and 50 km of the site (see Figure 2.22 and Table 2.4), and 9 samples were obtained between 50 km and 100 km from the site (see Figure 2.23 and Table 2.5). The remaining 8 samples were collected more than 100 km from the Giant Mine. More details on the program and all the results are provided in Appendix B.

This sample distribution of more than half of the samples within 10 km of the site and the rest further away is considered to be a good representation of the potential influence of the Giant Mine on the level of COPC in country food. For the purposes of this assessment, samples more than 50 km from the site were considered to not be influenced by the Giant Mine and were considered to represent background. Information from the mushroom sampling (Appendix P) as well as from the GNWT Open soils File (Jamieson et al. 2017) indicates that the influence of the Giant Mine is within a radius of 25 km and areas outside this are not considered to be affected by the Giant Mine.

Appendix B provides a summary of the analytical data for the voluntary sampling program.

The initial voluntary sampling program allowed only a few months to collect samples; but as identified by the YKDFN, the sampling period was extended to accommodate the inclusion of additional samples, including some that are seasonal and were not available during the initial program. Therefore additional samples were collected through the voluntary sampling program in the spring and summer of 2017, including rat root, mushrooms, and rabbits. Additional analyses with the new data are presented in Appendix P.

Fish	1	Lake trout

2.1.9 Background

The Canadian Council of Ministers of the Environment (CCME 2016) indicates that natural background should represent the concentrations of chemicals in the environment that reflect natural geologic variations. This agrees with the discussion in the draft FCSAP guidance (FCSAP 2015a), which indicates that background is representative of the true range of concentrations associated with the geographic area of the site. Thus, the background samples selected for use in the risk assessment were from local areas around the Giant Mine, but outside of the area of influence. It should be noted that the FCSAP guidance document is a draft report and was provided by ECCC for use on this project; it should not be used on a wider basis until it has been finalized.

Many jurisdictions use an upper confidence level (95th or 98th percentile) to represent background as these percentiles encompass a large portion of variation in background whilst excluding extremes. These upper confidence levels represent the highest concentration that is likely to represent background. Regulatory agencies such as the British Columbia Ministry of Environment (BCMOE) and Ontario Ministry of the Environment and Climate Change (MOECC) use this definition of background for setting cleanup standards/criteria.

The CCME, in developing more recent soil guidelines for nickel (2015a), beryllium (2015b), and barium (2013), has used an arithmetic average for defining background. The FCSAP background document (2015a) refers to United States Environmental Protection Agency guidance (U.S. EPA 2002) for developing an appropriate background concentration, which uses an average concentration for background when comparing to exposure areas. In the Exposure Section of the FCSAP document (FCSAP 2015a), it is indicated that if there is a suitable sample size (N>10), then background concentrations should be based on the 95% Upper Confidence Level of the Mean (95% UCLM).

The Giant Mine risk assessment follows FCSAP guidance (FCSAP 2015a), using an average statistic to describe background in the screening for selection of COPC (see Appendix D) and the 95% UCLM to describe background within the risk assessment calculations.

2.1.9.1 Soil

The Giant Mine sits on a mineralized zone known as the Yellowknife Greenstone Belt (YGB); this was considered in developing the background for soils. The Geological Survey of Canada (GSC) has compiled till soil data (Kerr 1999, 2000, 2001) associated with the geographical area of the Giant Mine site, and this dataset was used to determine the background soil concentrations for use in the risk assessment. These samples were collected at a depth that would not have been influenced by deposition of historical releases from the Giant Mine. Figure 2.24 shows a map of the soil sample locations in relation to the YGB. It should be noted that this dataset has also been used to develop the background concentrations in support of the GNWT clean up criteria for arsenic and is considered to be appropriate for use to establish background for the risk assessment. There are samples collected from various programs in and around the Yellowknife area (e.g., City of Yellowknife, Ndilo, Dettah, etc.) that fall within the range of the concentrations found in the GSC dataset. These data could be used to augment the GSC database; however, as these are areas that are considered to be exposure locations in the HHRA, a decision was made not to consider these data for the determination of background.

Appendix C provides the detailed methodology for determining the soil background used for the risk assessment calculations. As prescribed by the FCSAP (FCSAP 2015a) guidance, 95% UCLM values were used to describe background. For arsenic in soils, a concentration of 94 mg/kg was used to describe background in the Yellowknife Greenstone Belt. All locations with the exception of Dettah are in the YGB. For other areas, including Dettah, a regional arsenic soil concentration of 41 mg/kg was used to describe background. Appendix C provides background concentrations for all other COPC considered in the risk assessment.

Figure 2.24 Background soil sampling locations

Note: Area in yellow denotes the Yellowknife Greenstone Belt

2.1.9.2 Surface Water

The background locations selected were based on the ones generally used for the aquatic studies related to the Giant Mine Project and have been identified as Yellowknife River and Horseshoe Island located in Yellowknife Bay. However, there have been a few studies that have used Prosperous Lake as a background location. It should be noted that Prosperous Lake is located approximately 12 km northeast of Giant Mine and away from the direction of prevailing winds. Figure 2.25 shows the background surface water sampling locations. There are only three samples available in Prosperous Lake and the concentrations measured were similar to the other locations; therefore, Prosperous Lake was considered in the dataset to develop background. Based on a dataset of 19 samples, the background arsenic concentration is 0.6 µg/L. Appendix C provides the methodology for deriving the surface water background concentrations; it also provides the background concentrations for all other COPC considered in the risk assessment.

2.1.9.3 Sediment

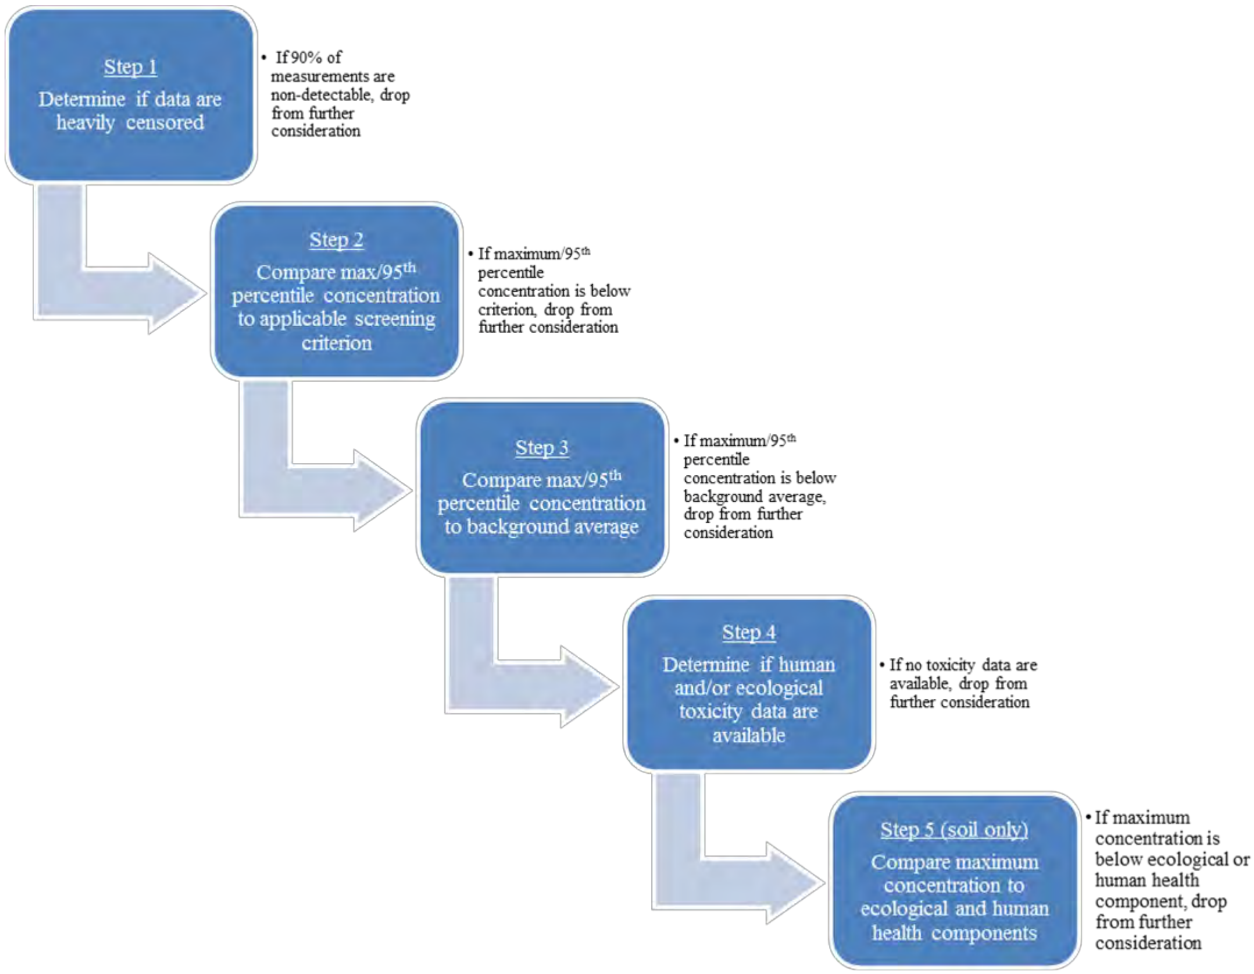
The background locations for the sediment samples were also considered to be Horseshoe Island and Yellowknife Bay, which were identified on Figure 2.25. These locations are representative of bay and river sediments. Concentrations in Yellowknife River were generally lower than those measured at Horseshoe Island. From an ecological risk assessment point of view, receptors were evaluated in both the lake and river environments and, therefore, the datasets were combined. From a human heath standpoint, combining the datasets results in a lower estimation of background concentrations and therefore represents a conservative estimate of background, especially for incremental arsenic exposure. The background sediment arsenic concentration was determined to be 23 mg/kg. Appendix C provides the methodology for deriving the sediment background concentrations; it also provides the background concentrations for all other COPC considered in the risk assessment.

Figure 2.25 Background surface water sampling locations

2.2 Constituents of Potential Concern

A tiered process was carried out to identify COPC in surface water and soil in the general vicinity of Yellowknife and the Giant Mine and involved an evaluation of measured environmental data. The general approach that was followed for selecting the COPC for consideration in the risk assessment involved using measured water and soil concentrations and comparing them to soil or water quality guidelines. This approach is shown in Figure 2.26. It should be noted that a soil concentration above a guideline does not necessarily mean that there is an actual risk to human health or the environment. A comparison to background concentrations was also done, and information on this can be found in Appendix D. Only chemicals present in soils and water above the soil or water quality guidelines or background were selected to be evaluated in the risk assessment. A key consideration in the examination of the COPC is that the chemical selected should be associated with the operations of the Giant Mine.

Figure 2.26 General selection process for constituents of potential concern



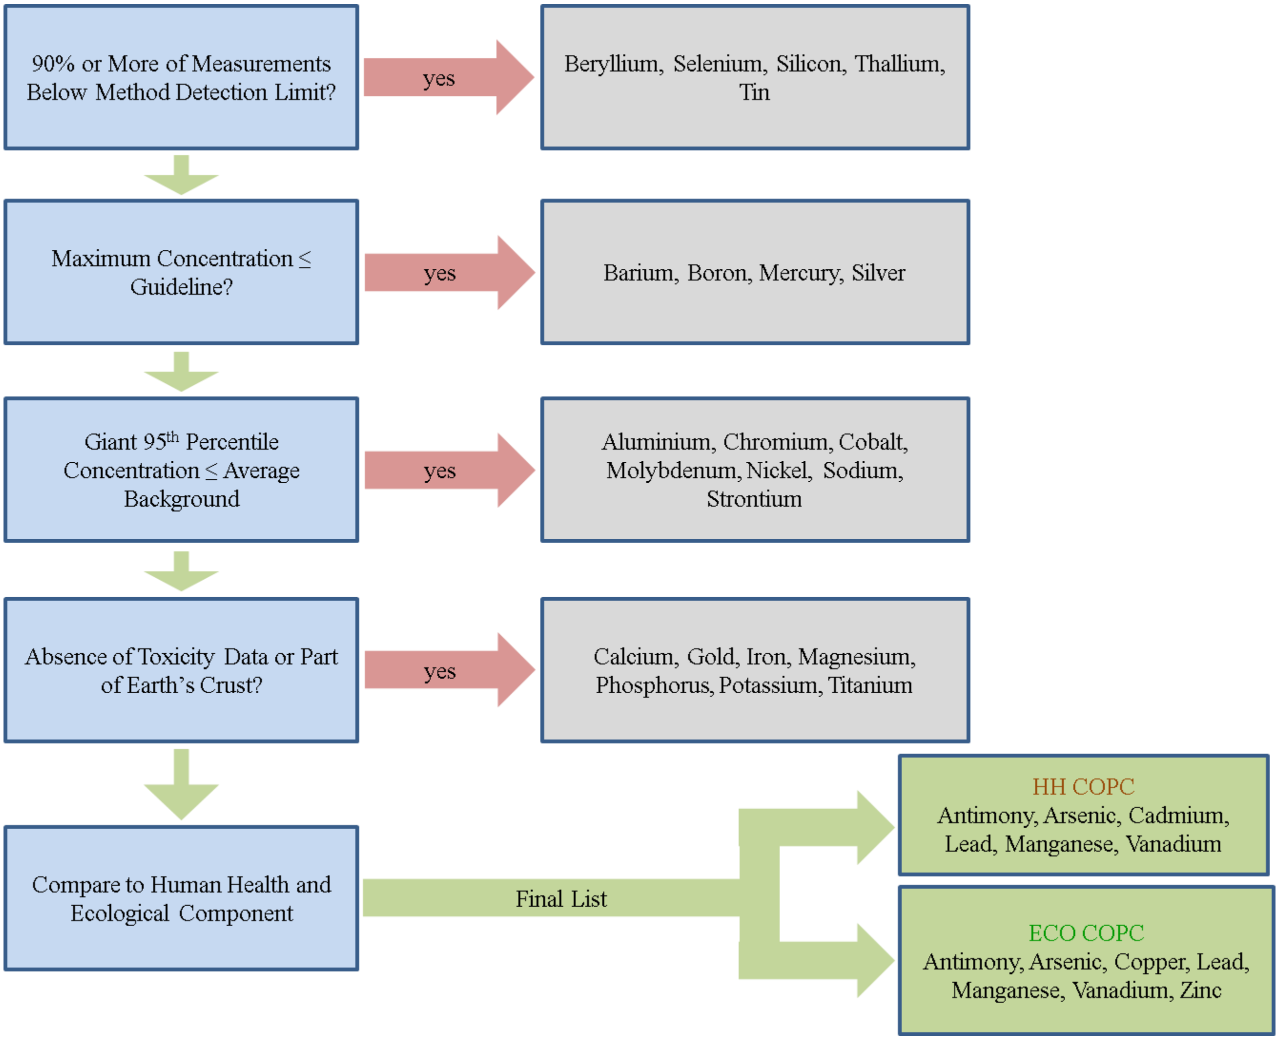
Other chemicals that may be present (such as petroleum hydrocarbons) would be present in localized areas associated with the disturbed areas. These would be addressed during remediation and were, therefore, not considered to be COPC.

Details of the COPC screen are provided in Appendix D and details on the derivation of background concentrations for the COPC screen are also provided in Appendix D.

2.2.1 Constituents of potential concern in soil

The soil COPC screen considered measured shallow soil concentrations from across the Yellowknife area. As soil concentrations generally change slowly over time, all data (from 1999 and onwards) were considered for the Yellowknife area. This ensures that both off-site and on-site conditions at the Giant Mine are considered. Analytical data has demonstrated that constituent concentrations are generally higher in surficial soils; in addition, this soil depth (≤ 10 cm) represents the likely exposure depth for both humans and wildlife.

Figure 2.27 Flowchart of soil constituents of potential concern screening results



For the soil COPC screen, the agricultural soil guidelines from the CCME (2017) were considered appropriate. The use of the most restrictive agricultural criteria ensures that all potential COPC are captured in the screening process. A summary of the screening process for COPC in soil is provided in Figure 2.27, while details on each step of the process are provided in Appendix D.

2.2.2 Constituents of Potential Concern in Surface Water

The surface water COPC screen was completed to identify COPC in Yellowknife Bay for humans (i.e., for the HHRA) that may use this water body as a drinking water source (i.e., not municipally treated and distributed) and to identify COPC in both Baker Creek and Yellowknife Bay for aquatic biota (i.e., for the ERA). Data for total metals collected from June 2011 onwards were considered in the process to represent current conditions as these data were collected after the JoJo tailings spill.

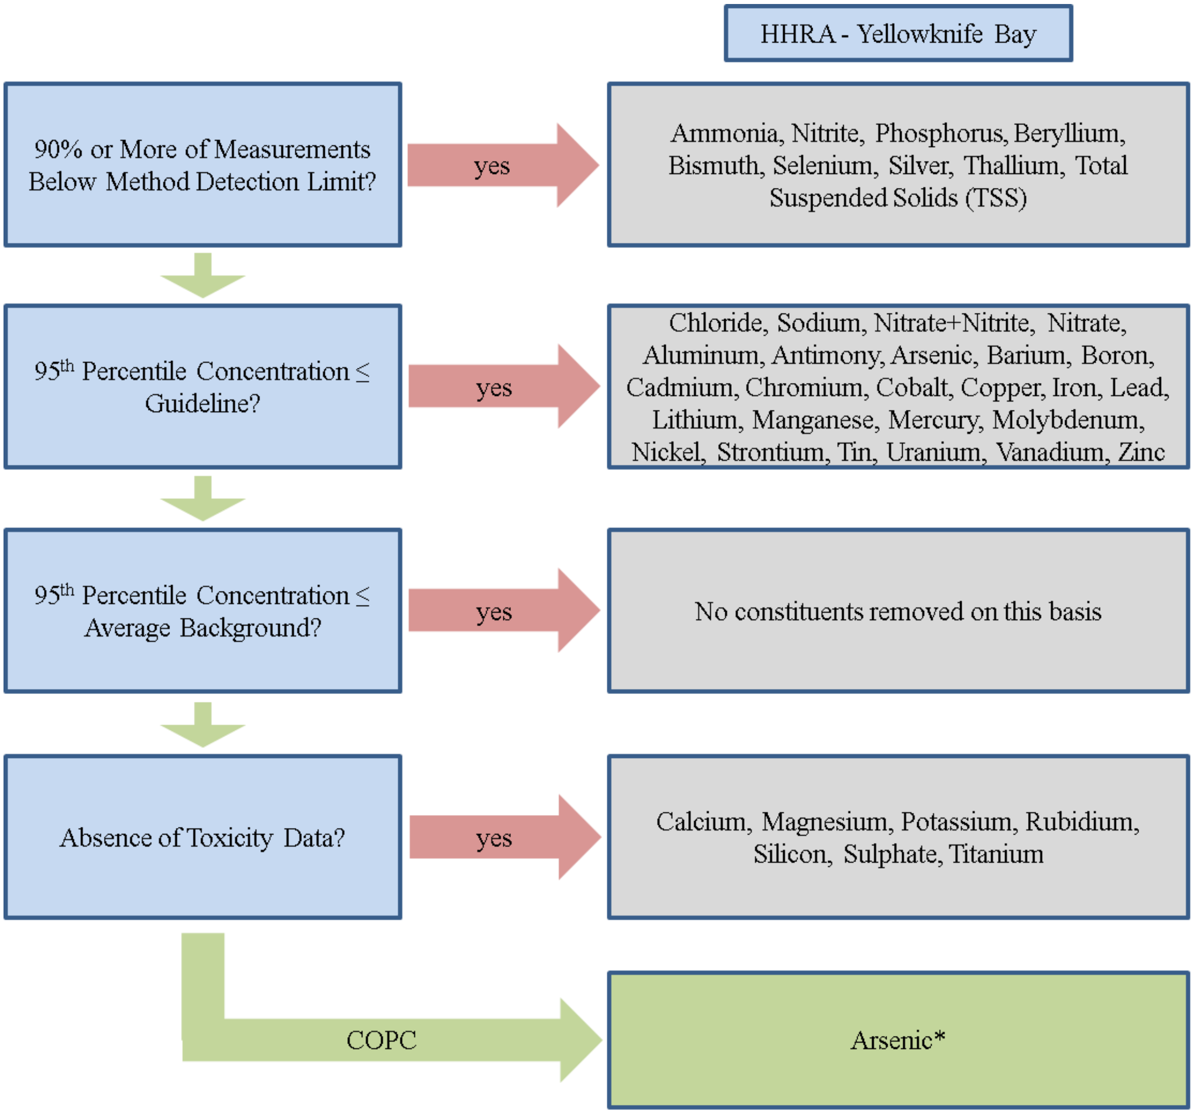
For Baker Creek, data from all reaches downstream of Baker Pond were included, as well as data collected from Back Bay at the outlet of Baker Creek. For Yellowknife Bay, data from all areas were considered, including Back Bay, North Yellowknife Bay (i.e., around Latham Island and Ndilo), and South Yellowknife Bay (i.e., east of Yellowknife and around Dettah). Due to the large number of measurements (close to 200 samples) available for each location, the 95th percentile concentrations of the measured data were used in the screening process. This approach eliminates outlier data and is considered to be a reasonably conservative approach.

For the HHRA, the Health Canada (2017) Guidelines for Canadian Drinking Water Quality were selected preferentially as the screening criteria. Health Canada indicates that these drinking water guidelines are maximum acceptable concentrations "designed to protect the health of the most vulnerable members of society, such as children and the elderly." considers water with concentrations of constituents below these values as safe to drink. Other sources of health-based drinking water guidelines were also consulted including the BCMOE (2010) Director's Interim Standards for Contaminated Sites for aluminum, iron, and manganese and U.S. EPA (2016a) Regional Screening Levels (RSLs) for tap water.

For selecting COPC for the ERA, surface water quality guidelines for the protection of freshwater aquatic life for long-term exposure from the CCME (2017) were considered. In the absence of a value from the CCME, other sources were consulted such as the Saskatchewan Environmental Quality Guidelines (SEQG; Government of Saskatchewan (GS 2015)), U.S. EPA (2016b) Water Quality Benchmarks for Aquatic Life, and the BCMOE (2017) Water Quality Guidelines to Protect Aquatic Life.

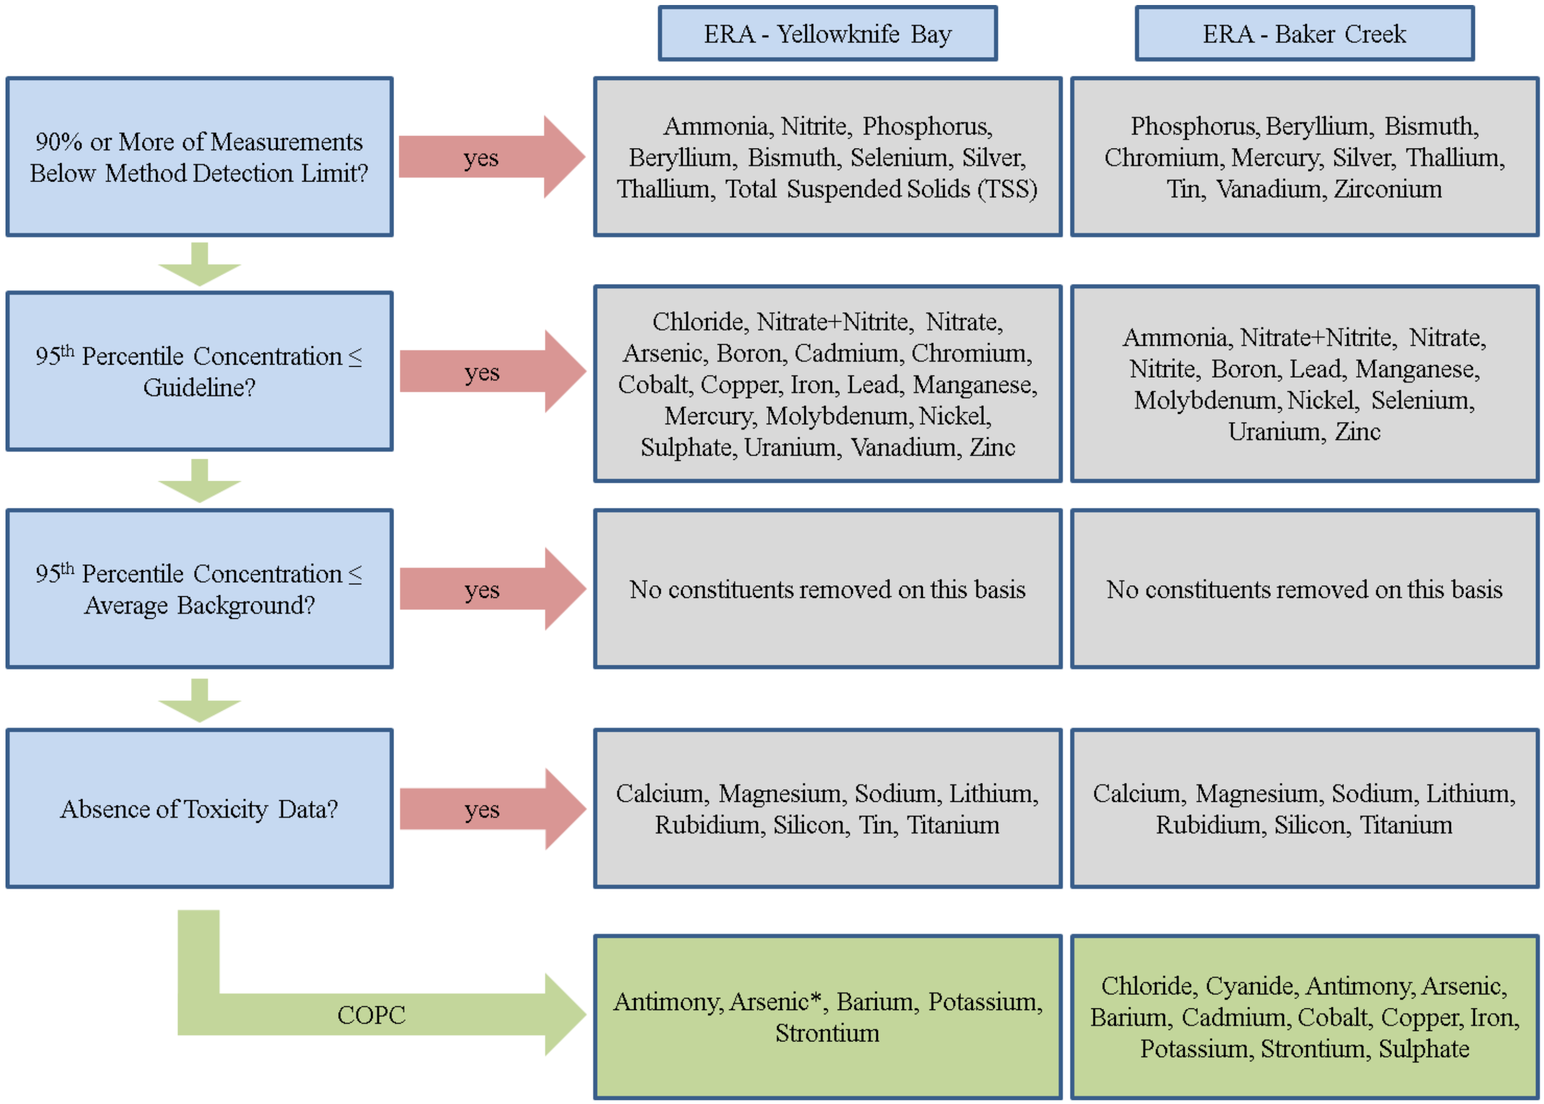
A summary of the screening process for COPC in surface water is provided in Figure 2.28 for the HHRA and Figure 2.29 for the ERA. Details on each step of the process are provided in Appendix D.

Figure 2.28 Flowchart of surface water constituents of potential concern screening results for the human health risk assessment



* Although arsenic concentrations were below the Health Canada Drinking Water Guideline in Yellowknife Bay, it was retained in the final list of COPC due to community concerns related to fish consumption and sediment contact.

Figure 2.29 Flowchart of surface water constituents of potential concern screening results for the ecological risk assessment



* Although arsenic was below the aquatic life guideline in Yellowknife Bay, it was retained in the final list of COPC due to community concerns.

2.2.3 Constituents of Potential Concern in Sediment

The available data on sediment was examined to determine whether any additional COPC should be added to the list. The process used sediment samples from Baker Creek and Yellowknife Bay. Data for total metals collected from May 2011 onwards were considered in the process to represent current conditions. For Baker Creek, data from all reaches downstream of Baker Pond were included as well as data collected from Back Bay at the outlet of Baker Creek. For Yellowknife Bay, data from all areas were considered, including Back Bay near Latham Island, North Yellowknife Bay near Ndilo, and South Yellowknife Bay by Dettah. Due to the large number of measurements available for each location, the 95% UCLM concentrations of the measured data were used in this approach, as this is considered to represent a reasonable exposure from sediments.

In this screening process, the 95% UCLM concentrations were compared to sediment quality guidelines for the protection of freshwater aquatic life for long-term exposure from the CCME (2017). The results of this process indicated that chromium, lead, mercury, and zinc were added to the COPC list for the Baker Creek, and chromium and copper were added for Yellowknife Bay.

2.2.4 Summary

The final list of COPC in soil, surface water, and sediment for the Giant Mine HHRA and ERA from this initial screening process is summarized in Table 2.6.

Table 2.6 Summary of constituents of potential concern for the human health and ecological risk assessment identified in initial screening process

Soil		Surface Water/Sediment		
ERA	**HHRA**	**Yellowknife Bay – HHRA**	**Yellowknife Bay – ERA**	**Baker Creek - ERA**
Antimony Arsenic Copper Lead Manganese Vanadium Zinc	Antimony Arsenic Cadmium Lead Manganese Vanadium	Arsenic	Antimony Arsenic Barium Chromium (*sed) Copper (*sed) Potassium Strontium	Chloride Cyanide Sulphate Antimony Arsenic Barium Cadmium Chromium (*sed) Cobalt Copper Iron Lead (*sed) Mercury (*sed) Potassium Strontium Zinc (*sed)

Note: Arsenic in Yellowknife Bay was measured below the drinking water guidelines as well as the guidelines for protection of aquatic life but was retained due to community concerns; *sed – Identified based on the sediment screen only.

3.0 HUMAN HEALTH RISK ASSESSMENT

3.1 Exposure Locations

The Giant Mine is an industrial site located close to the City of Yellowknife. Therefore, the HHRA evaluated the potential for exposures and risks from the Giant Mine on residential locations in and around the City of Yellowknife as well as locations where recreational activities take place. The locations selected for evaluation for human health were based on consultations with the WG and other interested stakeholders. The receptor identification took into account the diversity of inhabitants of the City of Yellowknife, Latham Island, the Ingraham Trail area, the communities of Ndilo and Dettah, as well as the wide range of land uses among these groups. Consideration was also given to future land use at the Giant Townsite area and the Giant Mine. Figure 3.1 presents the general geographic regions of the area, which were considered within the HHRA.

3.2 Problem Formulation

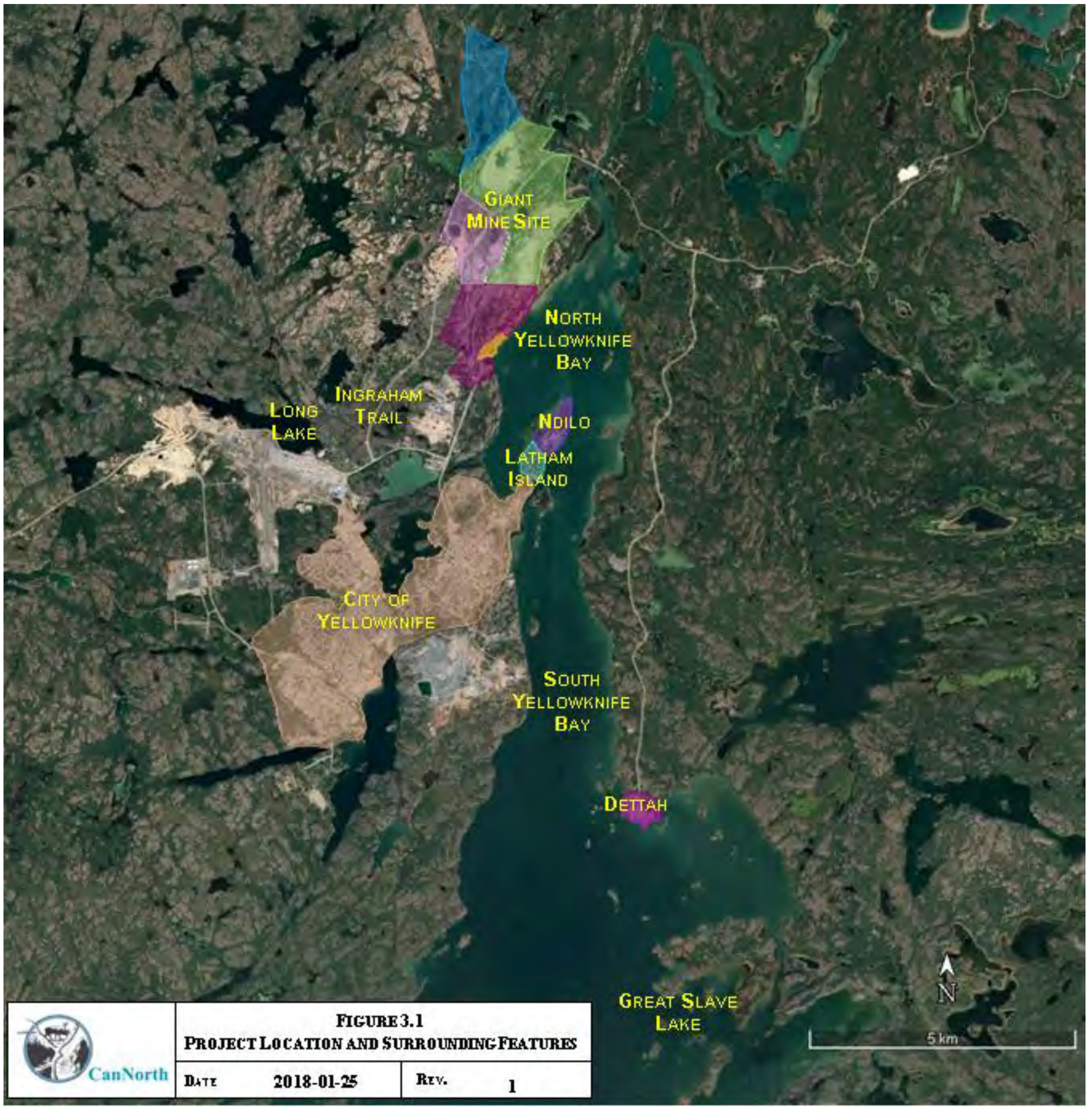
The problem formulation involved reviewing available data from all studies for the Giant Mine, as well as other information available from the communities including special sampling programs. This review helped to focus the approach of the study and lay the foundation for the HHRA. The following sections describe the different parts of the problem formulation for the HHRA. Section 2.0 provides a description of the site and the available information.

3.2.1 Hazard Identification

The initial COPC screen to identify COPC in soil and water for the HHRA was described in detail in Appendix D and summarized in Section 2.2. The result of the screening process for the HHRA for soils identified that antimony, arsenic, cadmium, lead, manganese, and vanadium were COPC from a consideration of all the soil data at the Giant Mine.

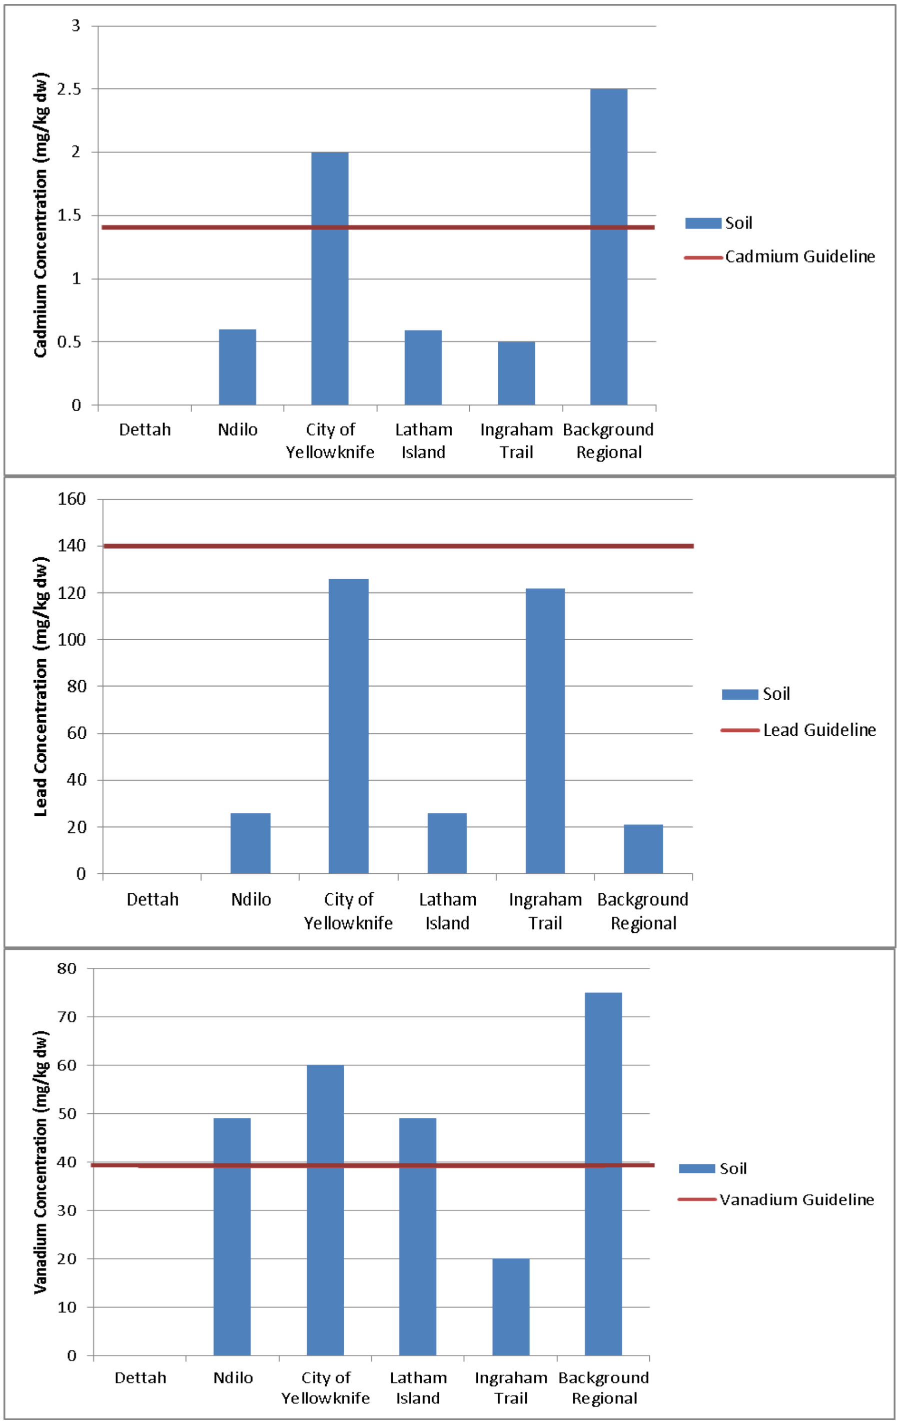
A qualitative assessment was carried out for the concentrations of the COPC in the soils at Ndilo, Dettah, Latham Island, City of Yellowknife, and Ingraham Trail. This qualitative assessment involved the comparison of concentrations at these locations to human health guidelines and/or background. Background concentrations are provided in Appendix C. The details of the qualitative assessment are provided in Appendix F.

Figure 3.1 Project location and surrounding features



Based on the qualitative analysis on the soils, cadmium, lead, and vanadium concentrations are below guidelines and/or background and, thus, do not represent a risk to human health. Figure 3.2 provides a representation of the screening process. As seen from the figure, concentrations of cadmium in soil are all below the guideline with the exception of the City of Yellowknife where the cadmium concentration is below background. Thus cadmium is not considered further in the risk assessment. All measured lead concentrations in soils at all locations are below guidelines and vanadium concentrations in soil, while above the guideline, are all below background. Therefore, the remainder of the discussion for human health will focus on arsenic, antimony, and manganese. Additional soil data available for Ingraham Trail and Dettah from work conducted by Queens University (Jamieson et al. 2017) does not result in changes to the qualitative assessment.

Figure 3.2 Summary of qualitative analysis for cadmium, lead, and vanadium



3.2.2 Receptor Identification

The people selected for evaluation in the HHRA were identified from the Problem Formulation (Stantec 2015b) as well as findings from consultation activities undertaken since the start of the project. This identification took into account the diversity of the people living in the City of Yellowknife, Latham Island, the Ingraham Trail area, and the communities of Ndilo and Dettah as well as the wide range of land uses among these groups. Consideration was also given to a future land use at the former Giant Townsite location as well as the Giant Mine. At present, there are no fixed plans for how the former Townsite will be used in the future; therefore the risk assessment took a conservative approach and assumed that people may build houses and live in this area. In order to provide a comparison of the impact of the remediation activities in the former Townsite, an unrealistic scenario of people living at the Townsite in its current condition was also evaluated. Figure 3.3 presents the locations that are assessed in the HHRA. Appendix E provides more details on the receptor characterization. The following list outlines the people evaluated in the HHRA:

- People (elders, adults, teens, children, toddlers) living in the City of Yellowknife. This also includes members of the Metis community.
- People (elders, adults, teens, children, toddlers) living in the community of Ndilo.
- People (adults, teens, children, toddlers) living on Latham Island, other than in the Ndilo community.
- People (elders, adults, teens, children, toddlers) living in the community of Dettah.
- People (adults, teens, children, toddlers) residing on the Ingraham Trail. There were some samples collected along the Ingraham Trail, and these samples were used to evaluate the residential exposure.

Concern has been expressed about children wading in shallow sediments in the communities of Ndilo and Dettah and also at the Marina near Latham Island. In addition, exposure at the beach at Long Lake and the shallow sediments has also been identified as a concern during consultations. The assessment considers all life stages exposed to sediments. It was also assumed that Yellowknife residents would swim in Long Lake. During meetings on the draft risk assessment, it was expressed that the YKDFN wanted analysis of their community using Long Lake as well as people from Latham Island and Ingraham Trail. These additional scenarios are presented in Appendix P.

Workers at the Giant Mine as well as Highway workers working close to the site have been identified as potential people to consider; however, workers were not included in the HHRA as they have their own, very rigorous, health and safety protocols and regulations. At the Giant Mine in particular, there are many programs in place, and the urinary arsenic program for on-site workers would also capture the exposure of workers who live in the community. In addition, during the COPC screening process, concentrations in the soil at the Giant Mine were compared to industrial/commercial guidelines, which are considered to be protective of worker exposure, and in addition to arsenic, only antimony concentrations were higher than the guideline. Antimony is known to be co-located with arsenic; thus, health and safety procedures targeted at protection from arsenic would protect workers from antimony as well. This provides additional evidence not to consider workers further.

The students of the K'àlemì Dene School in Ndilo were also identified for consideration since they consume lunches of fish caught in Yellowknife Bay and there were some elevated arsenic soil concentrations in the school yard. In Ndilo, all soil samples are considered in the residential scenario, including the high arsenic samples measured in the soils. Eating fish from North Yellowknife Bay where nets are set to catch fish for school lunches was also considered. Exposures for children living in Ndilo are for a longer time period (i.e., 24 hours a day, 365 days a year) than when they are at school (i.e., 6 hours a day for a maximum of 300 days a year) and, thus, capture potential exposures at the school.

As discussed above, a range of life stages (toddler, child, teen, and adult) were considered in risk calculations. Exposures for infants were not evaluated because it was assumed that they would be mainly consuming breast milk. It is not expected that COPC such as arsenic would be found at high concentrations in breast milk in either the current or future scenarios. Samanta et al. (2007) supports this statement with the finding that breast milk had low concentrations of arsenic even when women were being exposed to high levels of arsenic in their drinking water. Carignan et al. (2015) conducted a study that compared breastfed infants to formula-fed infants and determined that breastfed infants had lower arsenic exposure than formula-fed infants. These studies support the exclusion of infants in the risk assessment.

Figure 3.3 Human receptor locations

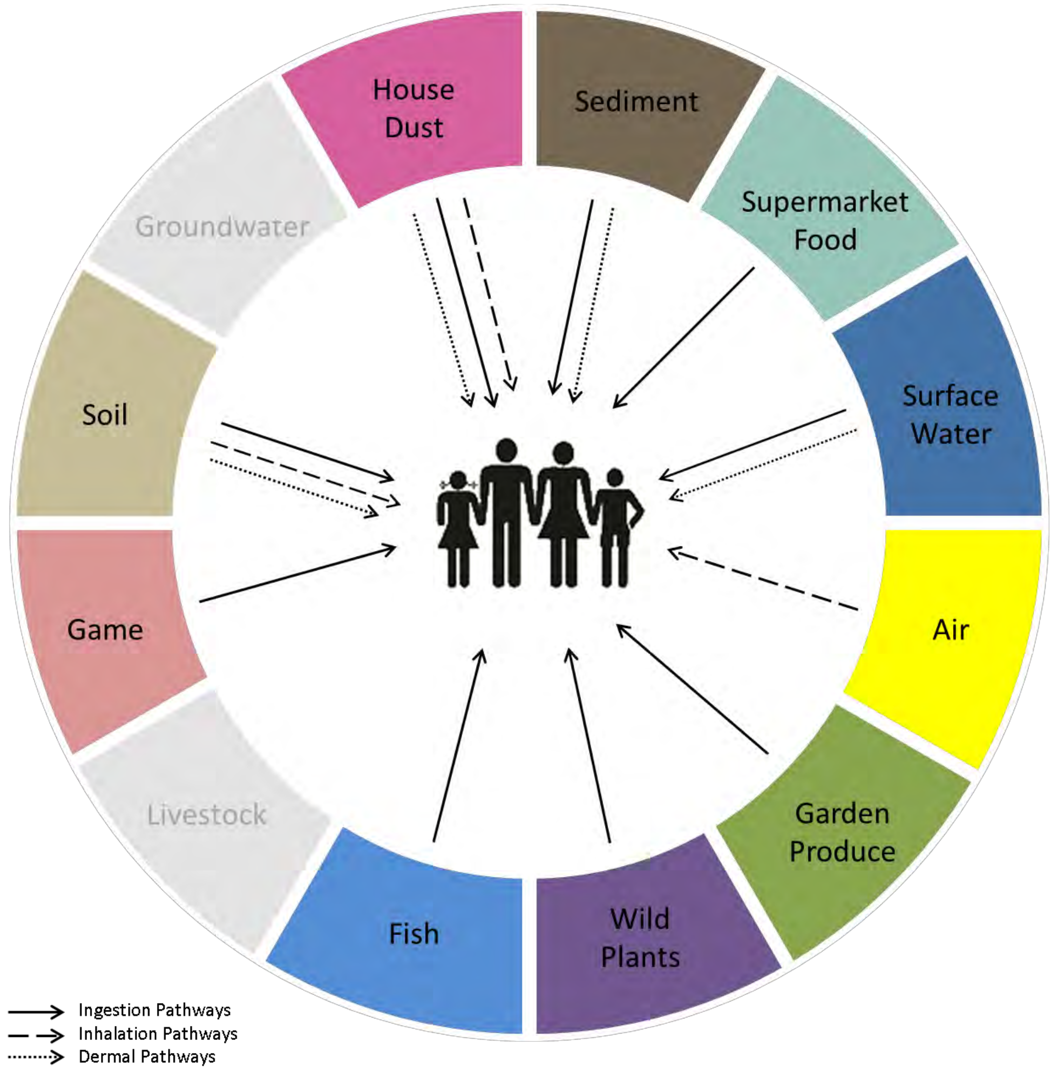
The Fred Henne Park and Long Lake have been identified as areas where people from the City of Yellowknife go to camp and swim. This recreational scenario is considered in the assessment.

3.2.3 Exposure Pathways

The ways that people get exposed (exposure pathways) were determined from consultations with the Giant Mine Working Group and other stakeholders by Stantec (2015b) as well as additional consultations by the CanNorth study team.

Figure 3.4 shows the potential exposure pathways that are evaluated for the current assessment.

Figure 3.4 Exposure pathways for the human health risk assessment



From the figure, the following ways of exposure are identified:

- Surface Water: People drink water from various sources. The municipal supply in Yellowknife comes from the Yellowknife River and people in the City of Yellowknife get pipe-borne water. In Latham Island, Ndilo and Dettah, the municipal water is delivered by tanker truck. However, there are also some members of the community in Ndilo and Dettah, as well as houseboaters, that indicate that they drink water directly out of Yellowknife Bay.

- Air: Metals such as arsenic may be present in the air and they can be breathed in by individuals.
- Soil: Individuals can come into contact with soil by gardening and other activities such as camping or being out on the land, and children and toddlers can be exposed by playing in soil. Chemicals in the soil can get into the skin by these activities, and soil on hands can end up in the mouth and be eaten. Exposures can occur outside the home, and if people are allowed to go onto the Giant Mine in the future for recreational activities, they can be exposed to soils on the Giant Mine.
- Dust: Dust in the house can have similar concentrations as soil, and dust can be picked up on hands and then ingested through hand-to-mouth contact.
- Sediment: Children have been reported to wade in shallow water along the shores of the Ndilo and Dettah communities, as well as near the marina and other areas on Latham Island, and concern has been expressed about this activity. In addition, playing on the beach can result in sediments getting on hands and then being transferred to the mouth. Sediment can also stick on the skin. The assessment considers all life stages wading in shallow sediment and being exposed to beach sediments.
- Fish: The City of Yellowknife and surrounding communities are located on Yellowknife Bay, and from the dietary survey, it was reported that a large proportion of people eat fish from different areas in the bay. Fish flesh and liver samples were collected from different kinds of fish in different locations in Yellowknife Bay.
- Moose: Because caribou cannot be hunted in the area anymore, more moose is being consumed, as indicated in the recent dietary survey. Moose flesh samples as well as organ (liver/heart) samples were collected from the community.
- Grouse/ptarmigan: The dietary survey indicated that people eat both grouse and ptarmigan from the area. Flesh samples as well as heart, liver, and gizzard samples were obtained from the community.
- Rabbit: The dietary survey indicated that people eat rabbit from the area. Information from other studies was considered along with samples from the community.
- Duck: People reported that they ate duck. Duck flesh samples were collected from the community.
- Medicinal Plants: In the dietary survey, people indicated that they drank Labrador tea, especially when they were on the land. In addition, they used different

medicinal plants, such as rat root and birch bark. Currently there are samples of Labrador tea, and this was used as a surrogate for all medicinal plants. Consideration of rat root and other medicinal plant data collected in the spring and summer of 2017 is shown in Appendix P.

- Berries: People collect berries from different locations across the study area. Many of the berries are collected at a distance from the Giant Mine; however, children in Ndilo have been reported to eat berries from local bushes. Samples have been collected from the community to represent exposure in all these areas.
- Mushrooms: The Metis community has indicated that their members eat mushrooms. Only one mushroom sample was provided by the community from the 2016 program. Additional mushroom data was collected in the spring and summer of 2017 and is provided in Appendix P.

In some places in Canada, drinking water may be obtained from groundwater wells. In the case of the City of Yellowknife and the surrounding communities, drinking water is obtained from the Yellowknife River municipal source or Yellowknife Bay. Given that these surface water sources are large and that there is no indication that the source of the municipal water system is likely to change, groundwater was not considered to represent a route of exposure.

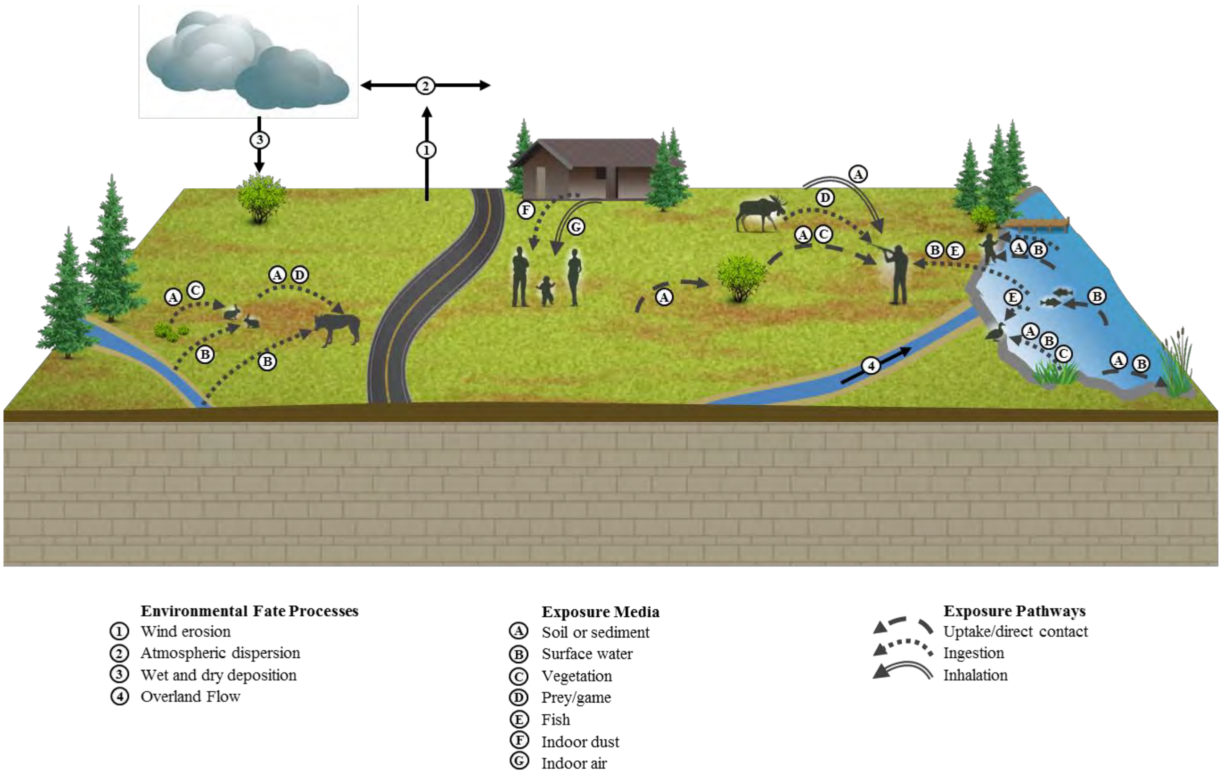
People do have vegetable gardens in the area; however, it was determined that most of the soil in these gardens (which are generally raised) comes from outside of the area or from compost from the City. An examination of the chemical concentrations in both the garden soil and compost indicated that concentrations were no different from background soil concentrations and, thus, were not influenced by the Giant Mine. In addition, in 2001 a risk assessment was carried out by the Royal Military College (ESG 2001b) related to exposure to arsenic from eating vegetables from backyard gardens in Yellowknife. This assessment involved the collection of soils and 61 different garden vegetables from 10 gardens across Yellowknife. The assessment considered the individual gardens as well as a garden that they considered to be representative of a typical resident in Yellowknife. The report concluded that even though residents in Yellowknife may eat garden vegetables with arsenic concentrations that are 10 times higher than in supermarket vegetables, when the amount of food consumed is considered there was no significant increase to the total daily intake of arsenic and therefore no indication that there was an increased health risk. Based on all these findings, garden produce was not considered further. Appendix E provides more details on the composition of the compost.

Children in particular may also drink small amounts of water from Yellowknife Bay water while swimming, playing on the shore, or boating. The assessment considers a resident drinking water from Yellowknife Bay and, thus, the exposure from these activities is accounted for within that scenario as people drink more water everyday than they do while they are swimming. City of Yellowknife residents were assumed to swim in Long Lake. The analysis of swimming in Long Lake by other people living in the Yellowknife area is provided in Appendix P. In addition, a scenario has been evaluated that considers people from Ndilo and Dettah swimming and wading in the Yellowknife River near the day use area (see Appendix P).

3.2.4 Conceptual Site Model

The Conceptual Site Model (CSM) for the Giant Mine HHRA is presented in Figure 3.5. A conceptual site model generally provides a picture to show the different pathways that are being evaluated in the risk assessment as well as the ways that the chemicals move from the soil, sediment, and water and are taken up by plants, fish, and other animals. The picture in Figure 3.5 captures many of the pathways that are being evaluated in the HHRA but does not include every pathway. For example, it shows a large animal, such as a moose, but does not show small animals, such as hare. The large animal is selected to represent all wild game.

Figure 3.5 Conceptual site model for the human health risk assessment



3.3 Exposure Assessment

Several different characteristics of individuals influence their exposure. These characteristics include how much they breathe, their body weight, how much water they drink, how much food they eat, and how much time they spend outdoors, to name a few. These characteristics are different depending on the age of the individual. For example, toddlers tend to eat more soil and dust since they are crawling and playing on the ground and then they put their hands in their mouths. Since they do not weigh very much, a toddler also tends to be the most highly exposed life stage in HHRA.

The exposure assessment involves the estimation of the intake of COPCs for people at Ndilo, Dettah, Latham Island, City of Yellowknife, and the Ingraham Trail using an approach that tends to overestimate exposures. The total intake for a COPC is the sum of the intakes calculated for each of the exposure pathways, including air, soil, water, sediment wading, and country foods. Calculating the intake rate of COPC uses the measured concentrations in air, water, soil, and sediments obtained from various sampling programs for the GMRP, as well as concentrations in country foods that were obtained from the voluntary sampling program in the community, and combines them with intake rates for each of the pathways. The intake rates for the country foods were obtained from the dietary survey that was conducted in the communities, and the other intakes related to how much water a person drinks etc. were obtained from values provided by Health Canada.

3.3.1 Fate and Transport Modelling

For the current scenario in the HHRA, measured concentrations for air, surface water, soils, and sediments at the various locations such as Ndilo, Dettah, Latham Island, Ingraham Trail, and the City of Yellowknife were used. For country foods, the measured concentrations in the country foods obtained from the voluntary sampling were used. For the unrealistic current scenario where it has been assumed that someone is living in the former Townsite area, measured concentrations were also used in combination with the measured country food concentrations. There were no indoor dust measured concentrations; therefore, the indoor dust concentrations were calculated from outdoor soil using a factor of 0.7 (U.S. EPA 1998). More details on the selection of this value are provided in Appendix F. The implications of this assumption were considered in a sensitivity assessment (Section 3.5.3).

For the future scenario, water and sediment concentrations in the future were predicted using simple fate and transport equations as outlined in Appendix K. These water and sediment concentrations were used to represent exposures at the various locations in the future. The soil concentrations at all the locations (Ndilo, Dettah, Latham Island, Ingraham Trail, and the City of Yellowknife) with the exception of the former Townsite will not change as the remedial activities on the Giant Mine will not have any affect in these areas. The future soil concentrations are discussed in Section 3.3.6.3.

3.3.2 Receptor Characterization

Information on human receptor characteristics were obtained from Health Canada or other authoritative sources, and include body weight, food, and drinking water ingestion rates, time spent outside, areas from which food (plants, fish, game) were obtained, etc., were defined in order to complete estimates of potential exposure. The YKDFN identified the need for an updated dietary survey; therefore, a dietary survey was completed in early 2017 to update the types and amounts of foods typically consumed by the YKDFN and Metis communities. Previous studies on the amount of food people consume were completed in the YKDFN community by the CINE in the mid to late 1990s (Receveur et al. 1996, 1998). In the current study, three workshops were held and a dietary survey questionnaire was developed to gather information on what country foods people from YKDFN and NSMA eat and where they get their country food from. This information was used in the HHRA to help reduce uncertainty in the use of data collected almost 30 years ago. Details of the survey results are provided in Appendix E. Reasonable assumptions were made or standard literature values were used for the other characteristics needed for the risk assessment, as described in the following sections.

3.3.2.1 Country Food Consumption

Based on the results of the January 2017 dietary survey and the NSMA questionnaire, the amount of country food that people reported eating was characterized for three different diets: a typical country foods eater from the YKDFN, a high country foods eater from the YKDFN, and a country food diet representative of the NSMA community. The country food diet of the NSMA community is also taken to represent Yellowknife residents who harvest, hunt, and fish. The assessment also considered people from the different locations that only eat supermarket food.

About five people from the YKDFN indicated that the only meat they consume is from country foods, and these people were captured in the high food diet. The largest number of people reported that country foods made up only 20% of their diet, and these people were captured in the typical food diet. A number of elders and young people in their 20s indicated that they either ate only food from the supermarket or food from the supermarket plus 5 to 10% country foods. Therefore, people with only a supermarket diet were also evaluated.

The survey also asked people how many portions of different country food they ate during a meal. For all meat and fish, a portion was described as the size of a palm of your hand and was equivalent to 85 g. For rabbit, the minimum reported amount corresponds to a person eating about 3 whole rabbits a year, and for grouse/ptarmigan, the minimum reported amount also corresponds to eating about 3 grouse a year. For berries, people were asked how many handfuls they ate, with a handful being equivalent to ½ cup or 50 g. The portions of food and the number of days reported for the three different types of diets are summarized in Table 3.1. The types of country food in the table are based on the different food samples collected in the voluntary sampling program. Additional details on the country food intakes are provided in Appendix E.

Table 3.1 Summary of the amount of country food eaten for three different diet assumptions

Country Food	Typical Country Diet	High Country Diet	Yellowknife Resident with Country Food Diet
Moose	2 portions/meal, 1 time/day, 15 days/year	3 portions/meal, 1 time/day, 30 days/year	1 portion/meal, 1 time/day, 12 days/year
Fish	2 portions/meal, 1 time/day, 365 days/year	3 portions/meal, 1 time/day, 365 days/year	1 portion/meal, 1 time/day, 210 days/year (4 days/week)
Rabbit	2 portions/meal, 1 time/day, 6 days/year	3 portions/meal, 1 time/day, 26 days/year	0.5 portion/meal, 1 time/day, 2 days/year
Grouse [a]	1 portion/meal, 1 time/day, 12 days/year	2 portions/meal, 1 time/day, 20 days/year	1 portion/meal, 1 time/day, 6 days/year
Duck	1 portion/meal, 1 time/day, 10 days/year	3 portions/meal, 1 time/day, 30 days/year	1 portion/meal, 1 time/day, 6 days/year
Muskrat	0.5 portion/meal, 1 time/day, 8 days/year	2 portions/meal, 1 time/day, 20 days/year	None
Beaver	1 portion/meal, 1 time/day, 4 days/year	2 portions/meal, 1 time/day, 24 days/year	1 portion/meal, 1 time/day, 2 days/year
Goose	2 portions/meal, 1 time/day, 4 days/year	3 portions/meal, 1 time/day, 8 days/year	1 portion/meal, 1 time/day, 2 days/year
Berries	1 portion per day, 15 times/year	1portion per day, 30 times/year	1portion per day, 15 times/year
Mushroom	None	None	½ cup once a month in spring and summer (4 months), adults only
Organs – Moose	1 portion, 2 days/year	1 portion, 2 days/year	1 portion, 2 days/year

Note: Based on dietary survey results for adults, 1 portion for meat and fish is equivalent to a palm size or 85 g. 1 portion for berries is equivalent to a handful, ½ cup or 50 g.
a – Combination of grouse and ptarmigan.

Since the dietary survey was completed by adults, it was necessary to make assumptions for the diets of elders, teens, children, and toddlers. Elder receptors were assumed to have the same ingestion rates as adults, while teen, child, and toddler receptors were scaled from adult rates, assuming 91%, 75%, and 50%, respectively. The value for teens is based on data from Richardson (1997) for First Nations people, and the values for child and toddler are based on data from a Canada-wide survey (Health Canada 1994).

The survey results also indicated that adults or elders ate organs and mushrooms. Therefore, the amount of organs from moose, fish, and grouse/ptarmigan that adults and elders eat also needed to be determined. The dietary survey provided information related to how much moose organs people eat (see Table 3.1); however, there was no information collected in the dietary survey on how much fish or bird organs people eat. Therefore, some assumptions were made to derive these values and are presented in Table 3.2. The assumptions were based on the weight of the organ in comparison to the whole body weight of the fish or bird. The amount of fish or bird organs was then determined by taking this percentage and applying it to the amount of meat people reported eating. For example, the fish liver is about 1 % of the fish body weight; thus, an adult or elder with a typical diet was assumed to eat about 2 g of fish liver (1% x 170 g fish flesh [2 portions]) every day. Thus, the amount of organs eaten assumes that people eat organs at the same relative rate as the meat from the rest of the animal. Specific values and ingestion rates are provided in Appendix E.

Table 3.2 Assumptions for size of fish and bird organs in comparison to the rest of the body

Food Item	Basis of Assumption
Fish Liver	Fish liver is approximately 1% of whole fish body weight.
Grouse heart	Grouse and ptarmigan heart is approximately 2% of whole body weight.
Grouse gizzard and liver	Grouse and ptarmigan gizzard is approximately 5% of whole body weight.

Specific ingestion rates determined for the adult and elder receptors are provided in Table 3.3, and the ingestion rates used for all receptors are provided in Appendix E.

Table 3.3 Summary of ingestion rates for adult and elder receptors

Country Food	Daily amount of country food eaten (g/d)		
	Typical Country Diet	High Country Diet	Yellowknife Resident with Country Food Diet
Meat	18.6	95.5	6.8
Fish	170	255	49
Berries	2.5	4.9	2.5
Organs	2.4	3.7	1.1

Note: Based on dietary survey results for adults and assumptions for organs; averaged over 365 days.

Medicinal Tea Intake

About ½ of the people surveyed indicated they drank Labrador tea. However, it was difficult to determine how much tea they drank and how much of the leaves went into the preparation; therefore, a number of assumptions were used to derive how much medicinal tea people drink. These assumptions are outlined in Appendix E. The values used for the typical country diet, high country diet, and Yellowknife resident with a country food diet were 0.05 g/d, 0.5 g/d, and 0.03 g/d, respectively. Only adult and elder receptors were assumed to drink medicinal tea on a regular basis. In the fall of 2017, additional plant samples were obtained, some of which were brewed into a tea and sent for analysis. Appendix P provides the results of these samples.

3.3.2.2 Supermarket Food Consumption

In the assessment, it was assumed that people with country food diets also ate some supermarket foods. In addition, a person only eating supermarket foods was evaluated. Typical intakes of antimony, arsenic, and manganese from supermarket foods were obtained from literature and are presented in Table 3.4. There is some double-counting in the assessment, since supermarket intakes were not reduced to account for the foods obtained from local sources such as country foods.

Table 3.4 Summary of general Canadian supermarket food dietary intakes

Constituent	Intake (mg/kg-d)				Reference
	Adult/Elder	Teen	Child	Toddler	
Antimony	$3.3x10^{-5}$	$5.0x10^{-5}$	$5.0x10^{-5}$	$7.7x10^{-5}$	FSA (2009), with consideration of information presented in Health Canada (1979).
Arsenic	$8.0x10^{-5}$	$1.0x10^{-4}$	$2.0x10^{-4}$	$3.0x10^{-4}$	EC (1999), inorganic arsenic in food.
Manganese	0.056	0.059	0.087	0.11	Health Canada (2011).

Note: FSA = United Kingdom Food Standards Agency, EC = Environment Canada.

3.3.2.3 Water Intake

The average amount of water drunk by an adult (20+ years of age) and elder (70+ years of age), teen (12 to 19 years of age), child (5 to 11 years of age), and toddler (0.5 to 4 years of age) are provided by Health Canada (2012) and are 1.5 L/d, 1 L/d, 0.8 L/d, and 0.6 L/d, respectively. This is equivalent to about 6 glasses, 4 glasses, 3 glasses, and 2½ glasses of water a day.

3.3.2.4 Soil Intake

Appendix E provides a detailed discussion for the selection of how much soil people end up eating during outdoor activities. For this assessment, soil ingestion rates from Wilson et al. (2013) were used, with average values for the elder, adult, teen, child, and toddler of 1.5 mg/d, 1.6 mg/d, 1.4 mg/d, 21 mg/d, and 14 mg/d, respectively.

3.3.2.5 Indoor Dust Intake

People can also eat some indoor dust when it is present on their hands and they then put their hands in their mouth. For this assessment, dust ingestion rates from Wilson et al. (2013) were used, with average values for the elder, adult, teen, child, and toddler of 2.5 mg/d, 2.5 mg/d, 2.2 mg/d, 31 mg/d, and 41 mg/d, respectively. Further discussion on the selection of indoor dust intake rates is provided in Appendix E.

3.3.2.6 Sediment Intake

Similarly, sediments present on hands can also end up in the mouth from hand-to-mouth contact. The estimated sediment ingestion rates from the literature for use in human health risk assessments are limited. A discussion of the available information is provided in Appendix E. Wilson et al. (2015) provided rates of 72 mg/hr, 57 mg/hr, 18 mg/hr, and 20 mg/hr for hand-to-mouth contact for the toddler, child, teen, and adult, respectively, for on-land activities, such as playing in the sand on a beach where sediment is exposed. These rates were used for the beach exposure scenario. Wilson et al. (2015) also provides a suspended sediment ingestion rate of 7.7 mg/hr for all age groups for near-shore, in-water activities in shallow water (i.e., wading, walking, playing in water). These rates were used for the wading exposure scenario.

3.3.2.7 Swimming Water Intake

There is limited available information related to the amount of water someone can drink while swimming. The U.S. EPA (2011) provides an estimate of the amount of water an adult and child could drink while swimming, based on results from swimming pool experiments (Dufour et al. 2006). Dufour et al. (2006) considered that swimming behaviour of recreational pool swimmers may be similar to freshwater swimmers. Based on the information from the U.S. EPA (2011), the mean hourly rate of 21 mL/hr for an adult was used for the adult, elder, and teen, and the mean hourly rate of 49 mL/hour for a child was used for the child and toddler. The Chicago School of Public Health (Dorevitch et al. 2011) carried out a study of water ingestion during recreational activities. This study indicated that the upper confidence estimate of water ingestion during swimming was 35 mL/hr, which is similar to the average of the adult and child ingestion rates provided by the U.S. EPA (2011). Further details on the amount of water swallowed while swimming are provided in Appendix E.

3.3.2.8 Skin Contact

Soil

People can be exposed through soil sticking to the skin during different outdoor activities. Exposed skin surface areas for hands for the adult, teen, child, and toddler of 890 cm^2, 800 cm^2, 590 cm^2, and 430 cm^2, respectively, were obtained from Health Canada (2010a). Exposed skin surface areas for arms and legs for the elder and adult, teen, child, and toddler of 8,220 cm^2, 7,200 cm^2, 4,550 cm^2, and 2,580 cm^2, respectively, were obtained from Health Canada (2012a). The total body surface area is not considered, since clothes provide protection to other areas of the body. Estimates for soil loading to exposed skin (hands, arms, and legs) were obtained from Health Canada (2012a); these values are 1×10^{-7} kg/cm^2-event for hands and 1×10^{-8} kg/cm^2-event for arms and legs. Further details on the calculated soil loading rates are provided in Appendix E.

Indoor Dust

People can also be exposed to dust on ledges and other areas in the house when dust sticks to the skin. Exposed skin surface areas for hands for the adult, teen, child, and toddler of 890 cm^2, 800 cm^2, 590 cm^2, and 430 cm^2, respectively, were again obtained from Health Canada (2010a). Indoor dust exposure was considered to occur through hand contact only, since clothes provide protection to other areas of the body and hands are the most likely to be in contact with indoor dust. Dust loading to exposed skin (hands) was obtained from Health Canada (2011); this value is 2×10^{-7} kg/cm^2-event for hands. Further details on the calculated indoor dust loading rates for dermal exposure are provided in Appendix E.

Sediment

Sediment can also stick to the skin, and then COPC can be transferred through the skin. Weighted sediment adherence factors for skin for all life stages were calculated based on Shoaf (2005a) for children and Shoaf (2005b) for adults. Full body (hands, arms, legs, feet) exposure was considered for toddlers (3,000 cm^2), while children were assumed to have feet and leg exposure (3,790 cm^2). Teens, adults, and elders were assumed to have sediment exposure to feet only (1,080 cm^2, 1,200 cm^2, and 1,200 cm^2, respectively). Further discussion on the selection of appropriate sediment adherence factors is provided in Appendix E. It should be noted that sediments that are underwater are likely to be washed off while wading in water whereas wet sediments at the shoreline may to stick to the skin.

Swimming Water

While swimming, skin is in contact with water and thus COPC can be transferred. Exposed total body skin surface areas for the adult, teen, child, and toddler of 17,640 cm^2, 15,470 cm^2, 10,140 cm^2, and 6,130 cm^2, respectively, were obtained from Health Canada (2010a). Further discussion on the calculation of dermal loading rates for swimming is provided in Appendix E.

3.3.2.9 Body Weight

The body weights (bw) of a toddler, child, teen and adult are needed to calculate daily intake rates (mg/[kg (bw)-d]). For this assessment, the body weights used for the adult, teen, child, and toddler were 70.7 kg, 59.7 kg, 32.9 kg, and 16.5 kg, respectively (Health Canada 2010a).

3.3.2.10 Exposure Frequency and Duration

The exposure assessment considers how often and how long people are exposed by the different pathways identified above. Exposure frequency refers to the how often a person is exposed via a particular pathway, while exposure duration refers to how long over a year that the behaviour occurs. Appendix E provides a discussion on the determination of exposure frequency assumptions for the assessment, and a summary is provided in the following section.

The assessment considered exposure to food, drinking water, and medicinal plants for 7 days per week, 52 weeks per year, or 100% of the time.

For outdoor soils, it was assumed the ground will not have snow for approximately four months (May to September) of the year. This represents the time when the soil is considered to be accessible. This translates to an exposure frequency of 7 days per week, 16 weeks per year. Exposures to the skin were assumed to occur at a frequency of one event per day of exposure.

Recreational soil exposures, such as from hiking, were assumed to occur on the weekend during the summer months, or for 2 days a week, 10 weeks a year. Half a day of soil ingestion was considered for the recreational soil exposures. Similar to outdoor soils, skin exposures were assumed to occur at a rate of 1 event per day of exposure. It is noted that the recreational scenario is in addition to the normal residential exposure, so there is some overestimation of exposures via this pathway for the recreational soil scenarios.

It was assumed that exposure to indoor dust would occur 7 days a week, 52 weeks a year. As above, skin exposures were assumed to occur at a frequency of one event per day of exposure.

It was assumed that people would wade in nearshore sediments or visit the beach at Long Lake about 10 weeks year, or when the water is warm enough to swim. Wading was assumed to occur for 2 hours per day, 7 days per week, during the warmer weather. It was assumed that people would swim at Long Lake about 10 weeks year, or when the water is warm enough to swim. Swimming was assumed to occur for 1 hours per day, 3 days per week, during the warmer weather and in combination with wading..

Exposure is averaged over a specified period, which is representative of the exposure frequency and duration. For the food, water, tea, and indoor dust exposure pathways, the averaging period was selected to be 52 weeks per year, consistent with the exposure frequency assumed for these pathways. Exposures to soil and sediment are assumed to occur on a consistent basis seasonally, as opposed to periodic or at defined intervals over the course of the year. Therefore, for these pathways, the averaging period was selected to be consistent with the exposure duration; 16 weeks per year for outdoor soil, 10 weeks per year for recreational soil, and 10 weeks per year for sediment exposure. However, it should be pointed out that residents in the communities surrounding Giant Mine are exposed every day to COPC in indoor dust, drinking water, and supermarket and country foods, and shorter term exposures to soil and sediment outdoors during the summer are not isolated but are in addition to the on-going daily exposures. Therefore, these shorter term exposures increase the daily exposures during the summer period. Given that exposures occur every day it may be more appropriate to average the exposure over 365 days rather than the shorter times that were used in the risk assessment. The approach used in the risk assessment results in overestimates of exposures via the soil and sediment pathways.

For the consideration of potential effects from carcinogenic COPC, the various durations of exposure for each life stage were considered in order to estimate a composite risk to a receptor from exposure over their lifetime. A lifetime receptor was calculated assuming

4 years as a toddler, 6 years as a child, 8 years as a teen, 52 years as an adult, and 10 years as an elder, for a total of 80 years of exposure.

3.3.2.11 Exposure Assumptions

The assessment considered exposure to country foods from the various locations where people provided the voluntary samples. For the wild game (moose, muskrat, beaver, hare, ptarmigan/grouse), measured concentrations from the voluntary sampling program were combined and used for all receptor locations as it was a small data set. However, data for berries showed that there was a decrease in concentrations away for the Giant Mine and, thus, the berry locations were separated into Ndilo, within 10 km of Giant Mine, and distances greater than 10 km from Giant Mine. In addition, people reported that they had nets set in North Yellowknife Bay and, therefore, the assessment evaluated consuming fish from North Yellowknife Bay and South Yellowknife Bay. It is noted that the assessment did not evaluate eating fish from small inland lakes. The assumptions used in the risk assessment are summarized in Table 3.5. The assumptions of berry consumption at Ndilo account for the fact that children have been reported to pick and eat berries from bushes in the community. There are not enough berry bushes to support getting all the berries from Ndilo and, thus, a value of 5% of total berry intake was used, although an assumption of eating all berries from Ndilo was included as part of the sensitivity assessment (Section 3.5.3). Similarly, it was assumed that people in Latham Island may eat berries from their back yards, and this was assigned 5%. However, it is noted that most respondents in the dietary survey indicated that they collect their berries more than 10 km from the Giant Mine. As there are a few nets set in North Yellowknife Bay by the YKDFN, it was assumed that people in that community obtain 10% of their fish from North Yellowknife Bay and 90% of their fish from South Yellowknife Bay.

Table 3.5 Summary of exposure assumptions for fish and berries

Country Food	Location	Percentage from Location					
		Dettah	Ndilo	Latham Island	City of Yellowknife	Ingraham Trail	Townsite
Fish	North Yellowknife Bay (A2)	10	10	0	0	0	0
	South Yellowknife Bay (A3)	90	90	100	100	100	100
Berry	Ndilo	0	5	0	0	0	0
	Within 10 km of Giant Mine	0	0	5	0	0	0
	More than 10 km from Giant Mine	100	95	95	100	100	100

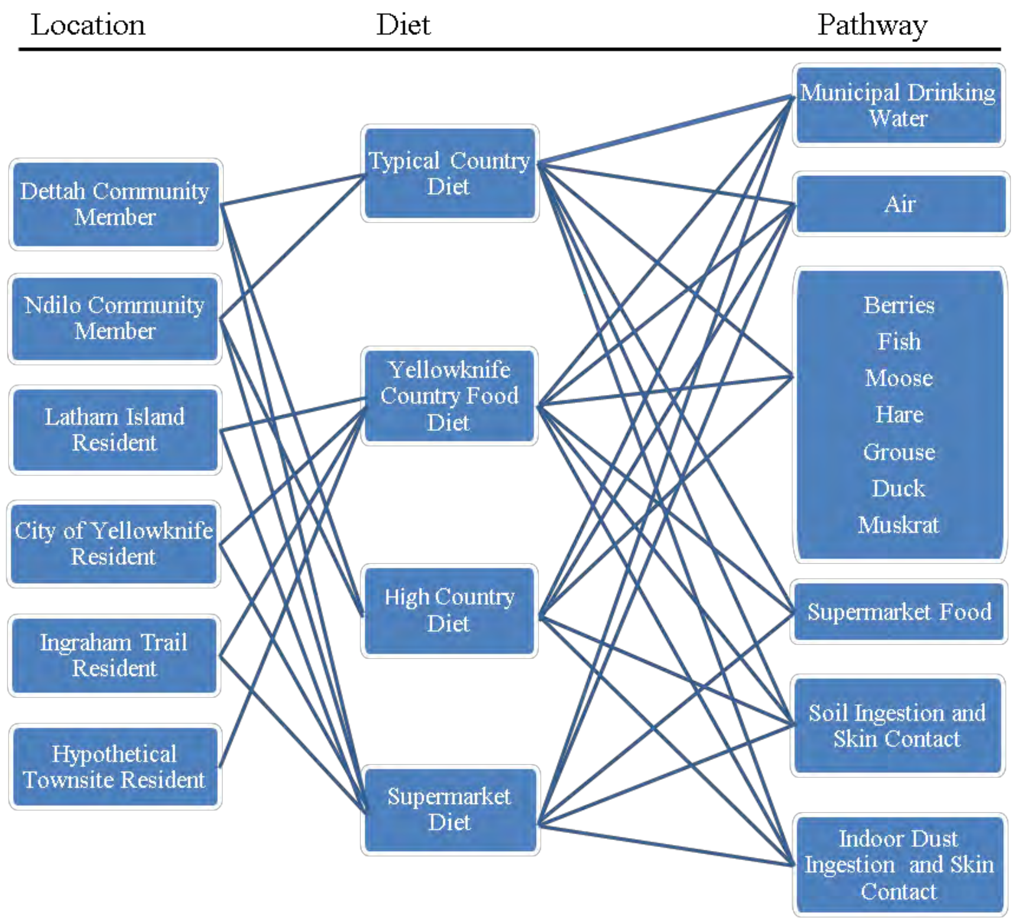
Note: Fish and berry locations based on dietary survey results.

3.3.3 Exposure Scenarios

3.3.3.1 Current

The exposure assessment estimated exposures to people living in the vicinity of the Giant Mine, with diets discussed in Section 3.3.2, and food from the locations where the country foods were collected. The exposure scenario that is considered to represent exposures for every location (i.e., base case) is provided in Figure 3.6. In the base case, everyone was assumed to get their drinking water from the municipal source and to be exposed where they live to concentrations in the air, soil, and indoor dust. Thus, this scenario captures the unique residential exposure in their areas. Members of the YKDFN community (Ndilo and Dettah) were assumed to have either a purely supermarket food diet, a typical country food diet that is also supplemented with supermarket food, or a high country food diet. People in the City of Yellowknife were assumed to have a diet consisting entirely of a purely supermarket food diet. In addition, because the Metis community also lives in Yellowknife and has some avid hunters and fishers, it was also assumed that people in Yellowknife would eat some country food as well as supermarket food. It was assumed that the Ingraham Trail resident and the Latham Island resident would also have a similar country food diet as residents in the City of Yellowknife. An unrealistic scenario was also evaluated where it was assumed that someone with a typical country food diet was living at the former Townsite. This scenario was used to demonstrate the impact of the remedial actions on the former Townsite location.

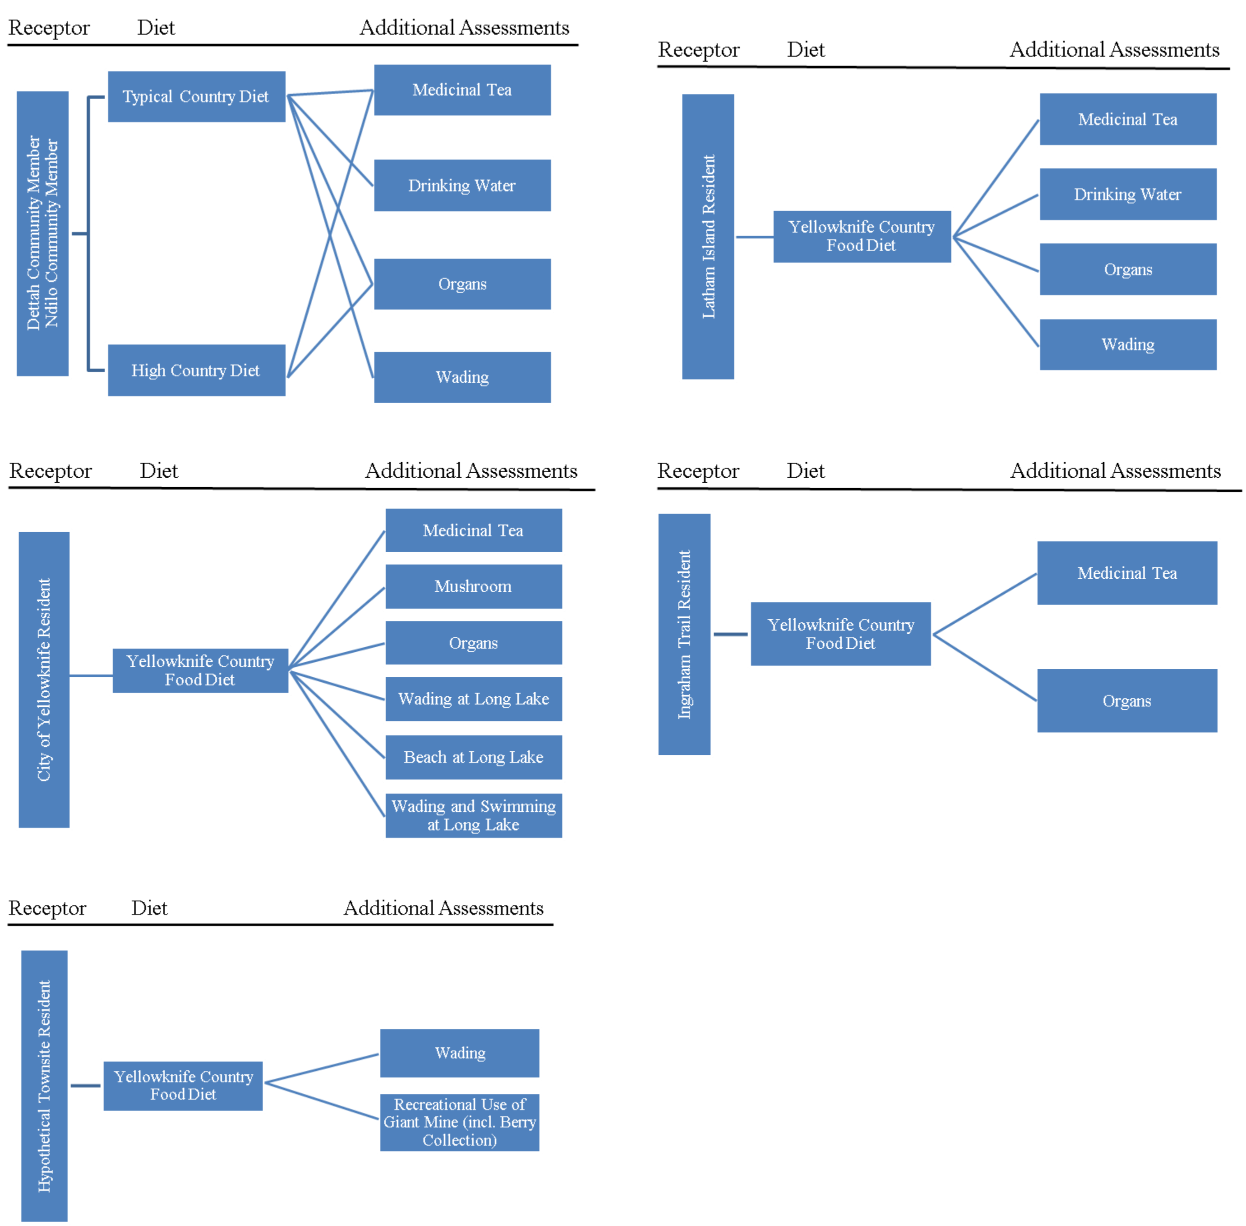
Figure 3.6 Base case exposure scenario



Other scenarios were also considered that were added to the base case. These scenarios are summarized in Figure 3.7. The scenarios for Ndilo and Dettah involve the assumption that people in these two communities would drink water from Yellowknife Bay instead from the municipal source and they would also wade in the shallow shoreline sediments. In addition, it was assumed that organs from moose, fish, and birds would be eaten and that they would drink medicinal tea. These same scenarios were considered for the Latham Island resident.

The Metis indicated in the dietary survey that they consumed mushrooms and, therefore, this scenario was considered for the City of Yellowknife resident that has a country food diet. In addition, the Fred Henne Campground and Long Lake were identified as areas where residents like to go and camp and swim/wade; thus, this scenario was considered. Eating organ meat and drinking medicinal tea was also evaluated for the City of Yellowknife resident, as well as the Ingraham Trail resident. For the unrealistic scenario at the former Townsite, it was assumed that people would currently wade in the shallow sediments. This wading scenario is also used to evaluate exposures at the boat launch and marina areas as the sediment concentrations are similar. An unrealistic scenario where people could access the Giant Mine under current conditions was also used to help frame the impact of the remedial activities. It is recognized that members of the YKDFN community do not want access to the Giant Mine.

Figure 3.7 Additional exposure scenarios considered



Note: It was assumed that Ndilo, Dettah, and Latham Island were assumed to get their drinking water from Yellowknife Bay.

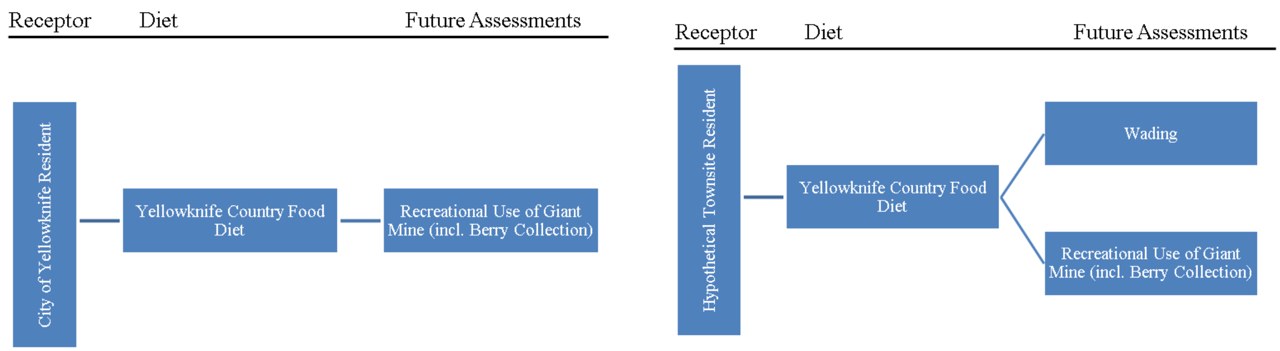
3.3.3.2 Future

The objective of the risk assessment is to determine what the effects of the remedial activities at the Giant Mine will have on the residents in the surrounding communities. The remedial actions at the Giant Mine involve the capping of the tailings, the remediation of arsenic concentrations in the disturbed areas of the site to the GNWT industrial criterion, the active management in terms of excavation and/or fencing of areas on the Giant Mine with arsenic concentrations above 3,000 mg/kg, and relocating the water treatment discharge pipe to near the mouth of Baker Creek. These remedial activities will not have any effect on the off-site community location exposures that were evaluated in the base case. In addition, remedial activities will not impact the concentrations in the country foods, as none of the samples were obtained from the Giant Mine. The remedial activities may allow for access to the Giant Mine for recreational activities such as walking, running, cycling etc., and this exposure was evaluated in the future scenario to help guide the remedial options planning. The effect of the relocation of the treated water discharge near the mouth of Baker Creek was evaluated using modelling to determine what the water and sediment concentrations would be in Back Bay and North Yellowknife Bay as described in Appendix K. The results determined that the concentrations in water and sediment in North Yellowknife Bay would essentially remain unchanged.

Figure 3.8 provides a summary of the exposure scenarios considered for future conditions. Public consultation has indicated that the YKDFN do not want to the Giant Mine to be used in the future; however other members of the public have indicated that they would like to use the site. Therefore, in the future scenario, it was assumed that people in the City of Yellowknife may be able spend some time on the remediated Giant Mine doing recreational activities. It was also assumed that, while they were on the site, they may pick some berries if they were in season (assumed to be 5% of total berry consumption). The consideration of people living in the City of Yellowknife would also account for residents on Latham Island and Ingraham Trail.

At the former Townsite, the remedial actions involve clean up of the soils to the arsenic GNWT residential criterion. No plans have been made for the final land use in this area; however, the risk assessment has evaluated the strictest land use where someone may live in this area. In addition, since this area is so close to the Giant Mine, it was assumed that people may be able to access the Giant Mine in the future. Additional details on exposure assumptions and scenario selection are provided in Appendix E.

Figure 3.8 Exposure scenarios for future conditions



3.3.4 Bioavailability/Bioaccessibility Assessment

Oral bioavailability is defined as the fraction of an administered dose that reaches the central blood compartment from the gastrointestinal tract. Bioavailability defined in this manner is commonly referred to as “absolute bioavailability”.

Relative bioavailability refers to comparative bioavailabilities of different forms of a substance or for different exposure media containing the substance (i.e., bioavailability of a metal from soil relative to its bioavailability from water), referred to as a Relative Absorption Factor (RAF). For skin contact, there are factors that account for the amount of a chemical that can be absorbed through the skin. RAF values for skin contact are available from literature and are provided in

Table 3.6 for the COPC considered in the HHRA.

Table 3.6 Dermal RAFs

COPC	Dermal RAF	Reference
Arsenic	0.03	Health Canada (2010b)
Antimony	0.1	MOE (2011)
Manganese	0.01	Health Canada (2010b), default

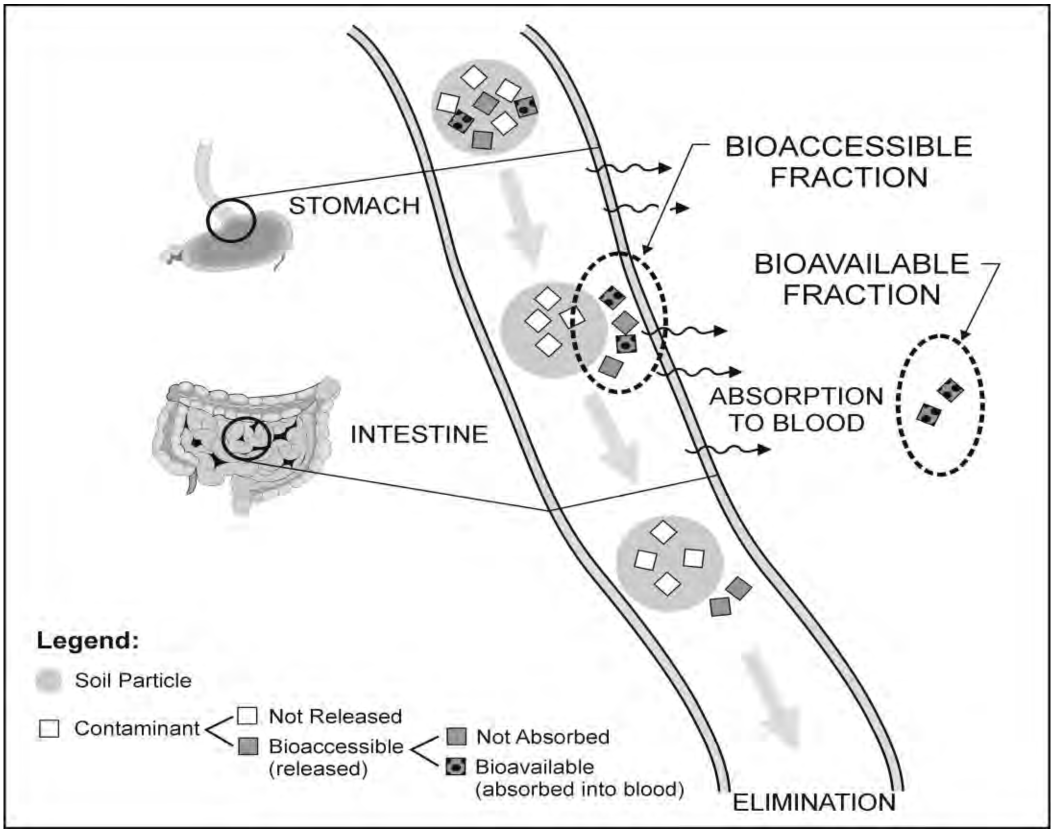
The oral bioaccessibility of a substance is the fraction of the administered dose that is soluble in a gastrointestinal environment and is available for absorption (into the central blood compartment). The bioaccessible fraction is not necessarily equal to the RAF but depends on the relation between results from a particular *in vitro* test system and an appropriate *in vivo* model. This is the measure of arsenic availability that is considered for the risk assessment.

Figure 3.9 provides a schematic representation of the difference between bioaccessibility and bioavailability.

For the Giant Mine HHRA, it was important to examine the bioaccessibility of arsenic in particular, since it was the primary COPC associated with the activities at the Giant Mine and since it is present in many different chemical forms (arsenopyrite, arsenic trioxide, etc.). Some of these forms can be absorbed into the bloodstream, while others cannot. In this study, laboratory analyses of soils, sediments, fish tissue and plants were conducted to determine the levels of arsenic that were available for exposure.

For the purposes of the Giant Mine, data on arsenic bioaccessibility in soils, sediments, and fish were obtained from samples collected in the study area as part of sampling programs for the GMRP. Bioaccessibility data for arsenic in plants and wildlife were obtained from a publication by Koch et al. (2013) related to bioaccessibility and speciation of arsenic in country foods from contaminated sites in Canada where Giant Mine was part of the study.

Figure 3.9 Schematic representation of bioaccessibility and bioavailability



The bioaccessibility of antimony and manganese were assumed to be 100% for this study as there were no available data. This represents a conservative assumption. Assumptions for the bioaccessibility of arsenic are described in the following section.

3.3.4.1 Summary of Arsenic Bioaccessibility Values Used in the HHRA

Appendix F provides a detailed discussion on all the bioaccessibility studies for various media that have been carried out as well as an analysis of the data for use in the risk assessment. Based on the bioaccessibility values provided in Appendix F, the specific assumptions for arsenic bioaccessibility for the HHRA are provided in Table 3.7. The soil bioaccessibility values for Long Lake and the former Townsite were all based on soil samples collected in those areas. For the Giant Mine site, the remedial plans indicate that an area of the site with arsenic concentrations above 3,000 mg/kg will be actively managed in the form of excavation and/or fencing. This area contains the disturbed soils and, thus, only the undisturbed soils were considered to represent exposure for humans. Thus, a bioaccessibility of 38% representing undisturbed soils was used.

For sediments, bioaccessibility data were available for sediments in Long Lake and along the shoreline of the Townsite. For the rest of Yellowknife Bay, it was assumed that the bioaccessibility of Townsite sediments was representative. This value seems reasonable as it is lower than the bioaccessibility of sediments in Long Lake and the undisturbed soils at the Giant Mine.

It was assumed that for lake whitefish, inconnu, and lake trout, the bioaccessibility was represented by the average value for all fish analyzed in Yellowknife Bay (Back Bay, Mosher Island, and background locations).

For medicinal tea, mushrooms, and hare, the bioaccessibility values were obtained from the literature for samples collected in the Yellowknife area (Koch et al. 2013). In the absence of data for other animals, it was assumed that the bioaccessibility of arsenic in the hare of 50% was considered to be representative.

The bioaccessibility of arsenic in other media (i.e., water, air, berry, organs) was assumed to be 100% in the absence of other information.

Table 3.7 Summary of arsenic bioaccessibility assumptions for HHRA

Medium	Location	Bioaccessibility Assumption	Rationale	Data Reference
Soil	Fred Henne Campground	36%	Average of five samples from Fred Henne Campground.	Site-specific; Golder (2016j), Table 17
	Townsite	30%	Average of eight samples from Townsite.	Site- specific Golder (2016j), Table 4
	Giant	38%	Average of nine samples representative of undisturbed soils.	Site-specific; Golder (2016j)
	All off-site locations including background	38%	Assumed to be represented by undisturbed soils.	–
Sediment	Long Lake	45%	Average of five samples from Long Lake.	Site-specific; Golder (2016g), Table 17
	Townsite	26%	Average of 10 samples from shoreline of Townsite.	Site-specific; Golder (2016g), Table 2
	Yellowknife Bay, including BG	26%	Assume same as shoreline Townsite sediments since in Yellowknife Bay.	–
Lake Whitefish	All	73%	Average of Back Bay, Mosher Island, and Background.	Site-specific; Stantec (2014d), Appendix C
Inconnu	All	38%	Average of Mosher Island and Background.	Site-specific; Stantec (2014d), Appendix C
Northern Pike	All	67%	Average of Back Bay, Mosher Island, and Background.	Site-specific; Stantec (2014d), Appendix C
Medicinal Tea	All	15%	Average of two samples from literature for Yellowknife area.	Koch et al. (2013)

Table 3.7 Summary of arsenic bioaccessibility assumptions for HHRA (cont'd)

Mushroom	All	70%	Average of 10 samples from literature for Yellowknife area.	Koch et al. (2013)
Hare	All	50%	Average of hare muscle from uncontaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Moose	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Grouse	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Hare	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Duck	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Muskrat	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Beaver	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)
Goose	All	50%	Assumed to be the same as average of hare muscle from contaminated areas from literature for Yellowknife area.	Koch et al. (2013)

3.3.5 Summary of Arsenic Speciation Values Used in the HHRA

Chemicals such as arsenic are found in different forms in the environment. Speciation is the process of determining the proportions of actual chemical forms in a sample since the chemical form can affect the bioavailability or bioaccessibility and relative toxicity of the chemical. For example, in fish, there are many forms of arsenic both in an inorganic and organic form. Many forms of inorganic arsenic are considered to be toxic (see Section

3.4); however, arsenobetaine (an organic form of arsenic) is considered to be non-toxic. The incorporation of speciation information in fish and other plants helps to increase the accuracy of, and confidence in, the health risk predictions. The discussion below focuses on arsenobetaine as all other arsenic species are considered to be as toxic as inorganic arsenic.

The specific assumptions for arsenic speciation with respect to arsenobetaine content were discussed in detail in Appendix F. Data on arsenobetaine are only available for fish and mushrooms as detailed in Appendix F.

The percentage arsenobetaine values used in the HHRA are provided in Table 3.8. As seen from the table for lake whitefish, northern pike, and inconnu, the percentage arsenobetaine was represented by the average percentage arsenobetaine from all locations in Yellowknife Bay (Back Bay, Mosher Island, and background locations).

For mushrooms, the percentage arsenobetaine was based on literature values pertaining to samples collected in the Yellowknife area. For all other samples, speciation of arsenic was not accounted for.

Table 3.8 Summary of arsenic speciation assumptions

Media	Location	Arsenobetaine Assumption	Rationale	Data Reference
Lake Whitefish	All	59%	Average of Back Bay and Mosher Island	Stantec (2014d), Appendix C
Inconnu	All	23%	Average of Mosher Island and Background	Stantec (2014d), Appendix C
Northern Pike	All	35%	Average of Baker Creek Outlet, Back Bay, Mosher Island, and Background	Stantec (2014d), Appendix C
Mushroom	All	33%	Average of eight samples	Koch et al. (2013)

3.3.6 Exposure Point Concentrations

Exposure Point Concentrations (EPC) are estimations of the concentration of a chemical in the environment and are generally a conservative estimate of the average chemical concentration in the environment. Appendix F provides a summary of the selected EPCs for the HHRA; a discussion of the data considered is provided in the following sections.

3.3.6.1 Country Food Exposure Point Concentrations

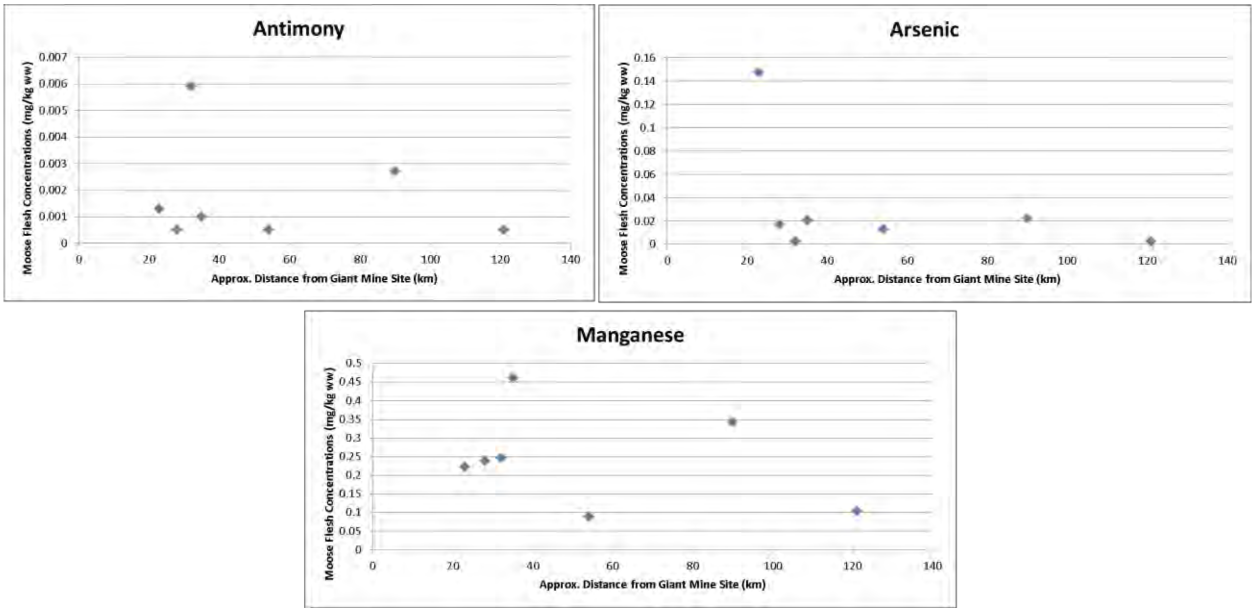
Section 2.1.7.1 provides a description of the voluntary sampling program for the country foods as well as the locations where the samples are collected, and Appendix B provides a summary of the data. The following discussion summarizes the results of the analyses of the country food samples for arsenic, antimony, and manganese and then develops the EPCs for use in the risk assessment.

Figure 3.10 shows the data for the eight moose meat samples plotting concentrations with approximate distance from the Giant Mine. Moose represents the most consumed meat in the 2017 Dietary Survey Update. There was a moose flesh sample with an arsenic level of 0.7 mg/kg on a wet weight basis (ww) that was obtained from a shoulder blade sample. Several statistical analyses were used to determine that this sample was an outlier for the arsenic concentrations in moose flesh. In addition, the concentration of arsenic in moose liver collected from the area is much lower than this measured concentration. Therefore, this sample was not considered in the development of the EPCs. However, it was considered as part of the sensitivity assessment (Section 3.5.3). The sensitivity analysis considered that all the moose consumed by people was at this elevated concentration. Figure 3.10 shows that there is no real trend in the concentrations of antimony and manganese in moose flesh with distance from the Giant Mine.

The arsenic concentrations in these moose flesh samples fall within the range of moose flesh data from samples across the Yukon which range from 0.01 to 0.4 mg/kg ww (Gamberg et al. 2005). Antimony concentrations in moose from the Yukon were reported below a detection limit of 0.01 mg/kg ww and manganese concentrations ranged from 0.005 to 0.56 mg/kg ww (Gamberg et al. 2005). Thus, the concentrations of antimony, arsenic, and manganese in the voluntary moose samples fall within this range of samples from other northern locations.

The moose liver sample had an arsenic concentration of 0.006 mg/kg ww, which is in the range of arsenic concentrations for 16 moose liver samples from the South Slave region (range 0.002 mg/kg ww to 0.044 mg/kg ww) and 12 moose liver samples from the Sahtu (range 0.002 mg/kg ww to 0.013 mg/kg ww) (GNWT 2015). No information was available for antimony or manganese concentrations in organs.

Figure 3.10 Moose meat concentrations with distance from Giant Mine



Note: A moose shoulder bone sample was found to be an outlier and the results of this sample are not shown in the figure. The HHRA considered this sample in the sensitivity analysis (see Section 3.5.3).

Figure 3.11 presents the measured beaver and muskrat meat concentrations with distance from the Giant Mine. There are four beaver flesh samples and only one muskrat flesh sample. The beaver sample captured farthest away from the Giant Mine has the highest concentrations of all three COPC; this sample was collected from Drybones Bay. The figure shows that the muskrat flesh concentrations for antimony, arsenic, and manganese are similar to the beaver concentrations and, therefore, these data were all pooled together. Two additional beaver samples were collected in the spring and summer of 2017 and the results are provided in Appendix P. These samples were obtained from areas more than 50 km from the Giant Mine, with arsenic concentrations of 0.12 mg/kg ww and less than 0.005 mg/kg ww. These concentrations are similar to concentrations obtained within 10 km of the Giant Mine.

Figure 3.11 Beaver and muskrat meat concentrations with distance from Giant Mine

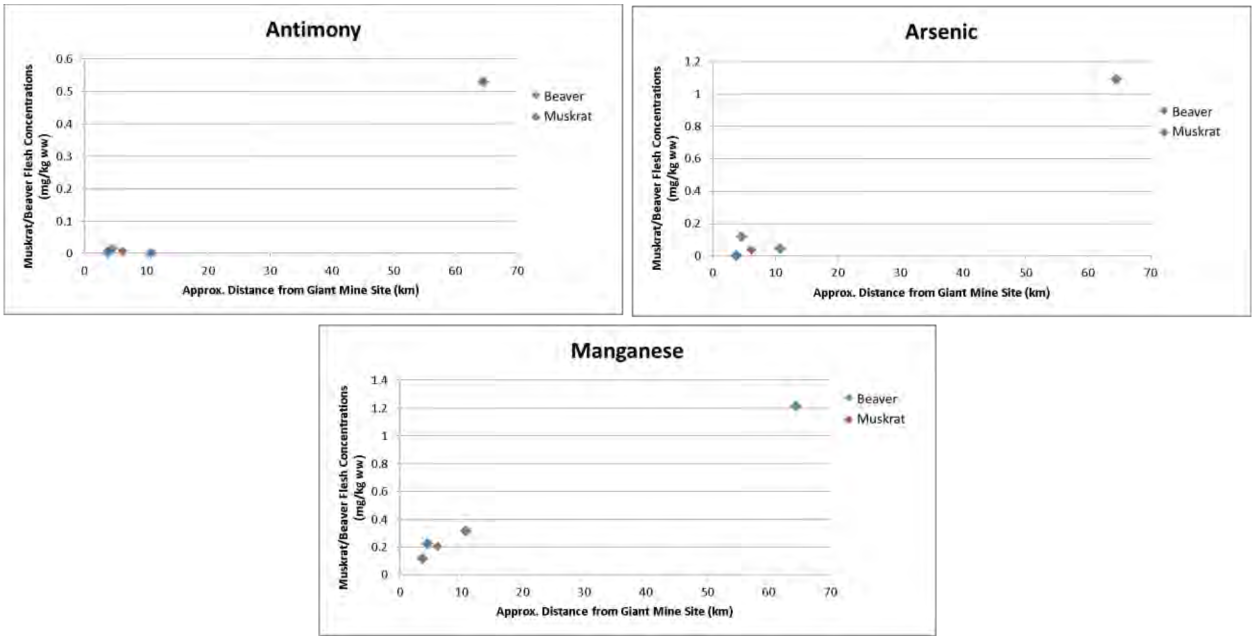


Figure 3.12 shows the two rabbit meat samples collected from the voluntary sampling along with arsenic levels in rabbits studied by Koch et al. (2013), both in contaminated areas of Yellowknife (four rabbits, shown in red) and in uncontaminated areas (three rabbits, shown in green); exact locations of the Koch et al. (2013) samples is not known. While there is a general trend with higher concentrations in the rabbit meat closest to the site, arsenic concentrations for both samples are within the range of rabbit concentrations reported by Koch et al. (2013) for rabbits from the uncontaminated areas in Yellowknife. An additional six rabbit samples were collected in the spring and summer of 2017 from Reid Lake and Prelude Lake, the results of which are provided in Appendix P. The range of arsenic concentrations in these samples was from less than 0.005 mg/kg ww to 0.01 mg/kg ww. These concentrations are similar to concentrations approximately 9 km from the Giant Mine shown on Figure 3.12.

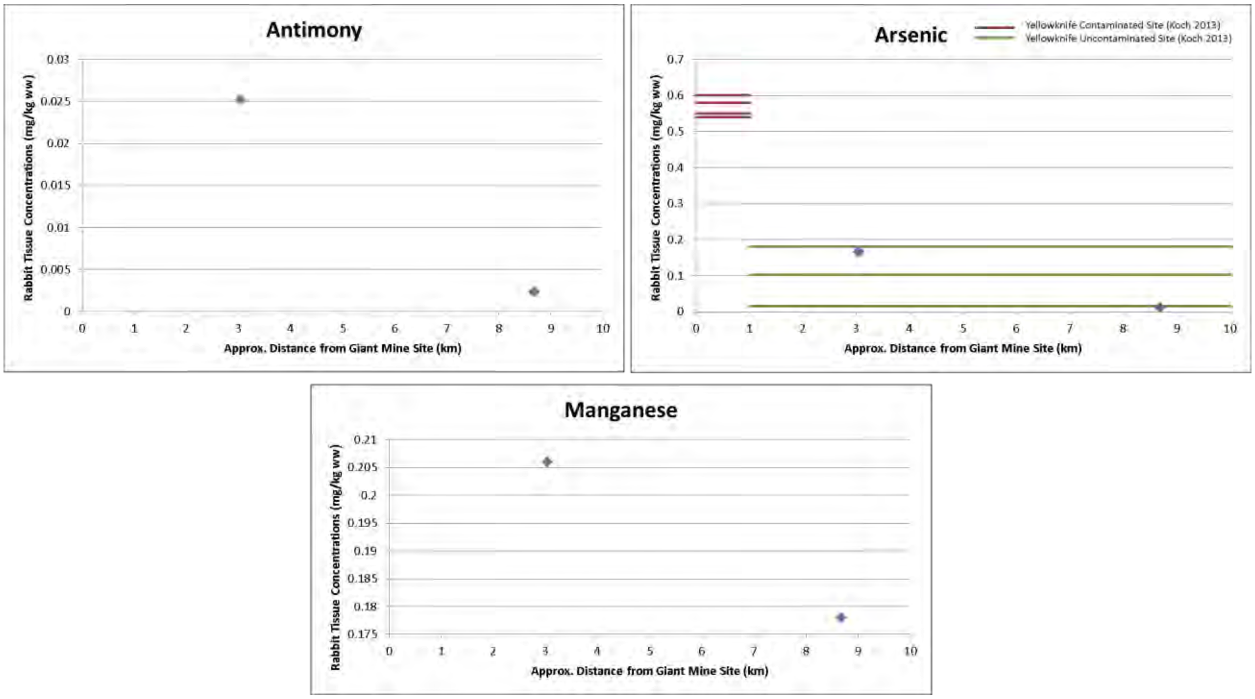
Figure 3.12 Rabbit meat concentrations with distance from Giant Mine



A summary of the duck and goose flesh concentrations is provided in Figure 3.13. These six samples include Lesser scaup, mallard, black duck/white winged scoter, and Canada goose. No clear trend is seen between concentrations and distance from the Giant Mine. The goose concentrations are similar to the duck concentrations so the data are combined.

Figure 3.14 shows concentrations for the four spruce grouse meat samples and the eight ptarmigan meat samples provided by the community. Three of the samples were collected from Vee Lake Road, within the Giant Mine lease boundary; these samples are the three plotted at approximately 3 km from the site. As can be seen in Figure 3.14, the antimony, arsenic, and manganese levels are similar in both the ptarmigan and grouse. Therefore, all the samples are pooled together. In addition, the concentrations in these samples are generally similar to concentrations seen in birds collected further away from the Giant Mine. In addition to these meat samples, samples of ptarmigan hearts and gizzards and spruce grouse gizzard and liver were also submitted for analysis and considered in the risk assessment.

Figure 3.13 Duck and goose meat concentrations with distance from Giant Mine

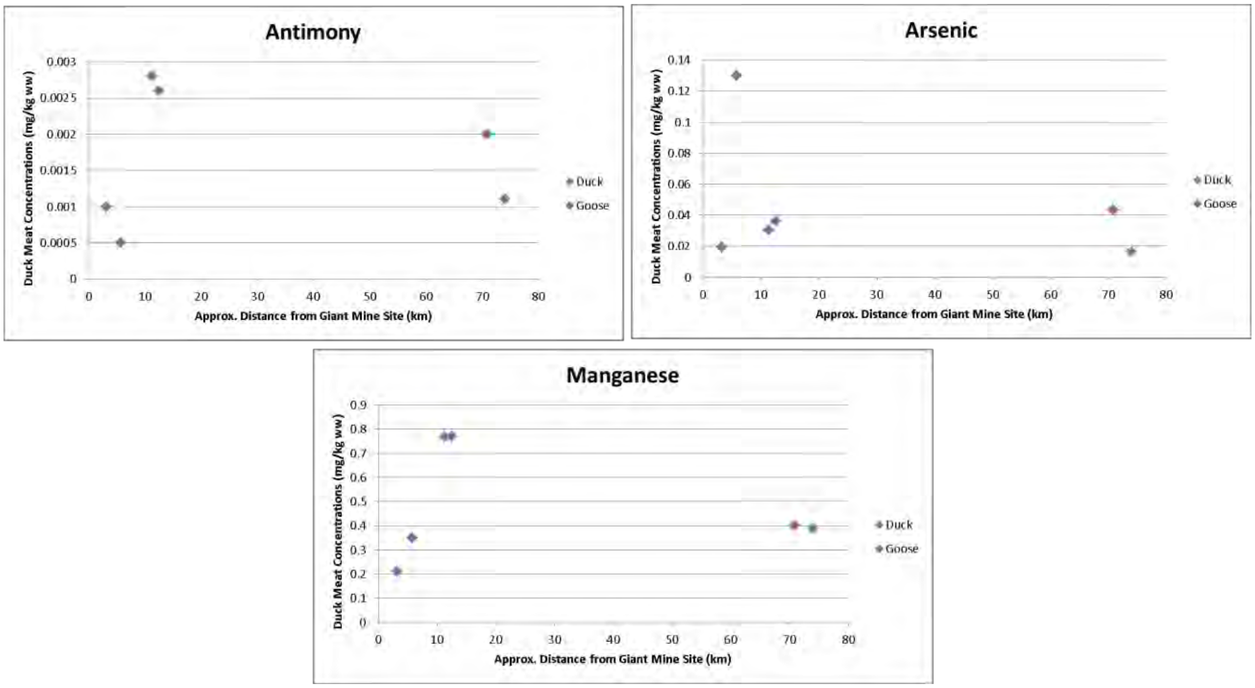


Figure 3.14 Ptarmigan and grouse meat concentrations with distance from Giant Mine

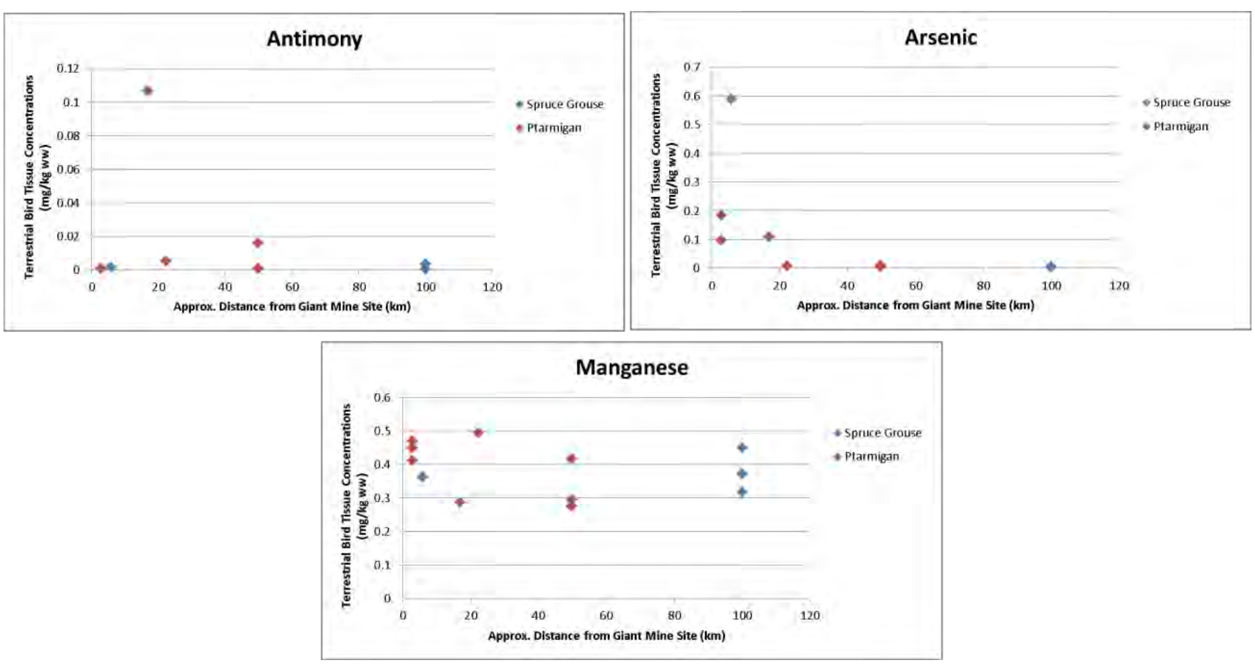
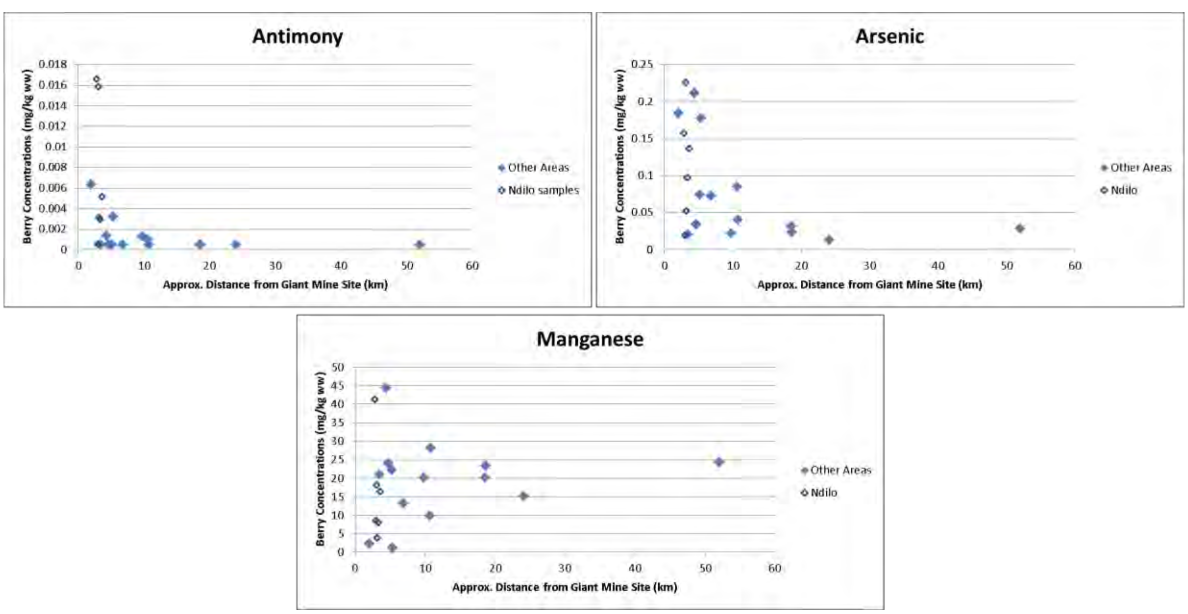


A summary of berry concentrations is shown in Figure 3.15. These 20 berry samples consist of cranberries, raspberries, Saskatoon berries, red bear berries, and rose hips. Six of the samples were collected from Ndilo; these samples are indicated by the open diamonds. As seen from Figure 3.15, there is a trend in antimony and arsenic concentrations with distance from the Giant Mine. There seems to be less of a trend in the manganese samples. The concentrations in samples from Ndilo are generally similar to those collected from other areas that are a comparable distance from the Giant Mine. It was noted that one rosehip sample and one mixed sample of Saskatoon berry/raspberry were grown in compost or mulch; the concentrations measured in these samples are within the range of the samples collected from native soils. Additional berry samples were collected in the spring and summer of 2017 from Ndilo and other areas around Yellowknife and the results are provided in Appendix P. The measured concentrations are similar to the concentrations shown on Figure 3.15.

In the summer of 1998, a study was initiated by the YKDFN to evaluate arsenic concentrations in berries (NCP 1999). Samples were obtained from around Yellowknife and Dettah, as well as the Con Mine, Giant Mine, and Salmita (an abandoned gold mine). A total of 51 samples were analyzed for arsenic. The concentration of arsenic in samples not collected from the three mine sites ranged from 0.01 mg/kg ww to 0.2 mg/kg ww. This range is similar to the arsenic concentrations measured from the voluntary sampling program shown in Figure 3.15.

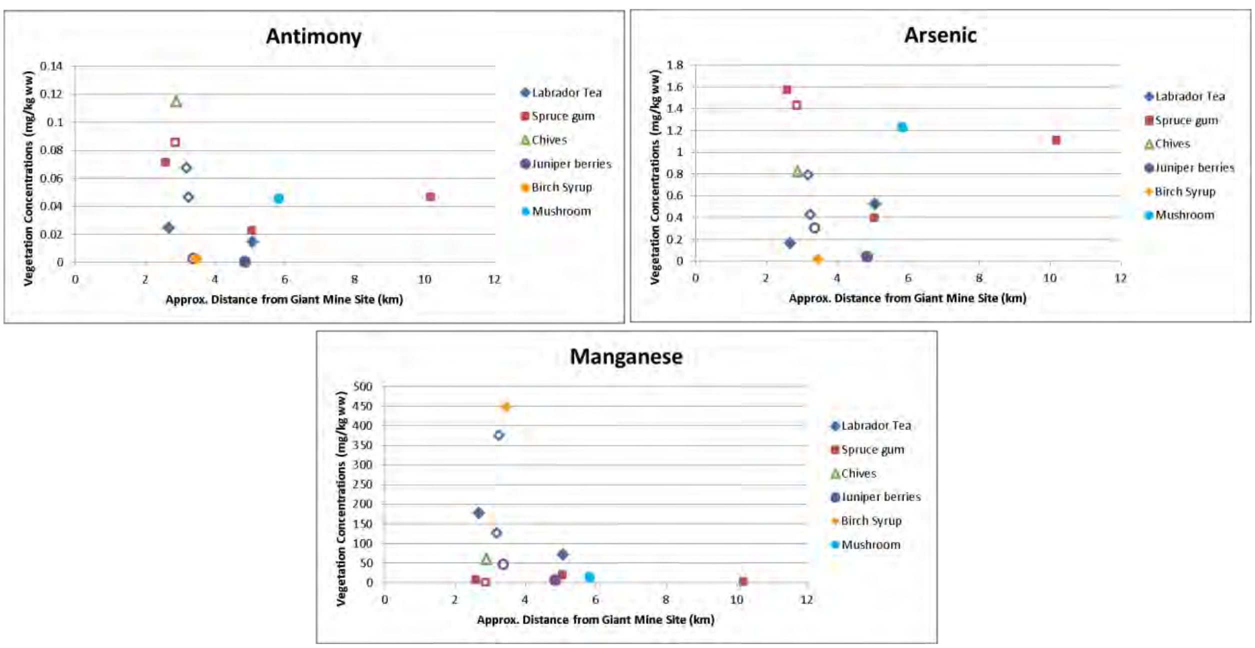
Figure 3.15 Berry concentrations with distance from Giant Mine



Note: Open symbols indicate samples from Ndilo, while filled symbols are from other areas.

Concentrations for other submitted plant and mushroom samples are shown in Figure 3.16. Similar to the comparison for the berries, a wider range of concentrations are seen closer to Giant Mine. There does not seem to be a difference between the samples from Ndilo (open symbols) as compared to samples from other locations (filled symbols) that are a similar distance from Giant Mine. Additional medicinal tea samples were collected in the spring and summer of 2017 from Ndilo and other areas around Yellowknife and the results are provided in Appendix P. The measured concentrations are similar to those shown in Figure 3.16. Rat root samples were collected as part of this program and the data showed that the concentrations were similar to background rat root concentrations (see Appendix P). A large number of mushroom samples were collected in the late summer of 2017 by Velma Sterenberg and the results are provided in Appendix P. These data were considered in the mushroom assessment.

Figure 3.16 Plant and mushroom concentrations with distance from Giant Mine



Note: Open symbols indicate samples from Ndilo, while filled symbols are from other areas.

Nine fish samples from the voluntary program were submitted for analysis. Seven were flesh samples (lake trout [five samples] and whitefish [two samples]), while the other two samples were whitefish eggs. A summary of fish flesh concentrations is shown in Figure 3.17 with approximate distance from the Giant Mine. The two lake trout samples collected from more than 100 km from the Giant Mine were from Lutsel K'e.

As seen from the figure, the concentrations of antimony, arsenic and manganese in lake trout are similar to those in lake whitefish. In addition, the concentrations of antimony, arsenic, and manganese are similar to concentrations in lake whitefish captured in other programs.

Figure 3.17 Fish flesh concentrations with distance from Giant Mine

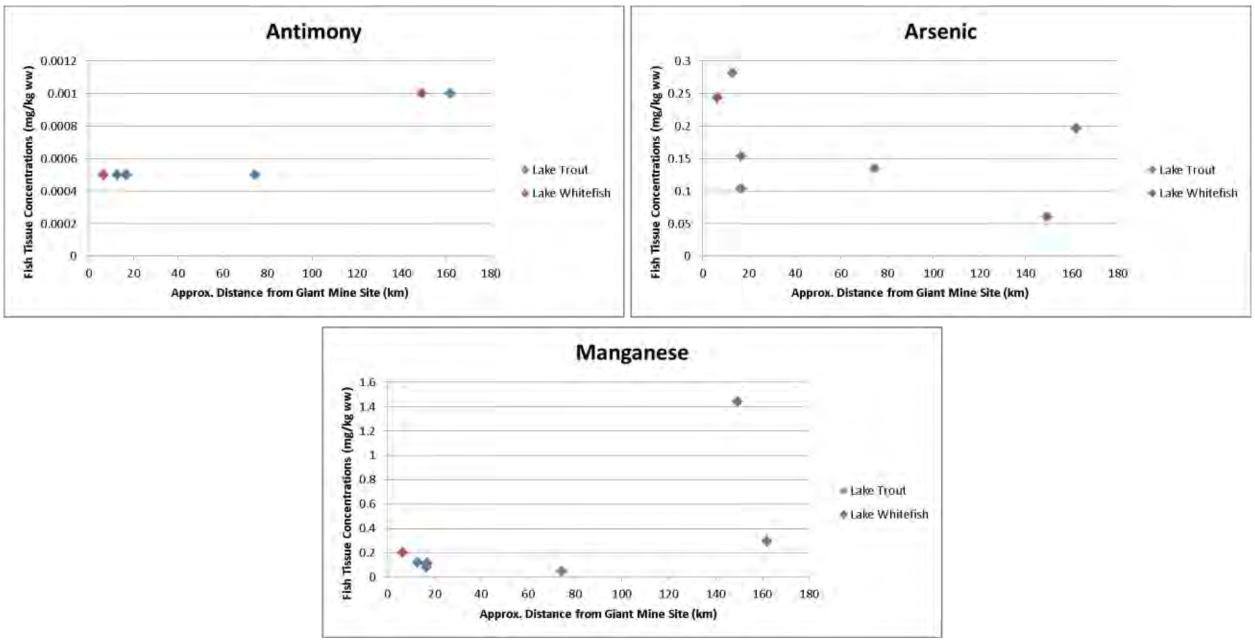


Table 3.9 provides a summary of the EPCs for antimony, arsenic and manganese in country foods that were derived from the voluntary sampling study. Lake trout samples are based on the voluntary samples while northern pike and lake whitefish samples are mainly based on scientific studies carried out in Yellowknife Bay. In determining dietary exposure estimates, the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization [WHO; (FAO and WHO 2008)] indicate that the average concentration of monitoring data is used since the use of maximum concentrations in food substantially overestimates the dietary exposure. Thus, average concentrations of COPCs in country foods were used in the risk assessment. Since people mostly eat fish and there are a large number of fish samples (over 100 samples), a 95% UCLM was used to represent concentrations in fish. Table 3.10 provides a summary of background concentrations of antimony, arsenic, and manganese in country foods. A comparison of the two tables shows that:

- Concentrations of antimony and manganese in five moose samples are similar to two background samples and arsenic concentrations are higher than background.
- Concentrations of antimony, arsenic, and manganese in three beaver/muskrat meat samples caught more than 50 km from the Giant Mine are higher than in the four animals caught closer to the site.
- Concentrations of arsenic in rabbit meat from samples close to the Giant Mine are higher than in five background samples; no data are available for antimony and manganese in background samples.
- Concentrations of antimony in five duck/goose meat samples are similar to those in two background samples; arsenic and manganese in duck/goose meat are slightly higher than background.
- Concentrations of manganese in nine grouse/ptarmigan meat samples are similar to those in three background samples; antimony and arsenic concentrations are higher than background.
- Concentrations of antimony, arsenic, and manganese in 30 lake whitefish in North Yellowknife Bay and South Yellowknife Bay are similar to those in 38 background samples.
- Concentrations of antimony, arsenic, and manganese in 16 inconnu samples in South Yellowknife Bay are similar to those in lake whitefish and in 40 background samples.
- Concentrations of antimony, arsenic, and manganese in three lake trout samples in South Yellowknife Bay are similar those in lake whitefish concentrations and two background samples.
- Concentrations of antimony, arsenic, and manganese in 22 northern pike samples in North Yellowknife Bay are similar to those in 20 samples in South Yellowknife Bay; arsenic and manganese concentrations are higher than those in 41 background samples.
- Arsenic concentrations in berries close to the Giant Mine are higher than concentrations in samples further away.
- Additional mushroom samples have been collected in the late summer of 2017 and are discussed in Appendix P. Appendix P shows that concentrations of antimony and arsenic in mushrooms from 25 km or greater from the Giant Mine are at background values whereas concentrations in mushrooms from within 10 km of the Giant Mine are higher than background.

Table 3.9 Summary of exposure point concentrations in country foods

Country Food	Exposure Point Concentration (mg/kg ww)			Comment
	Antimony	Arsenic	Manganese	
Moose	0.0018	0.04	0.25	Based on an average of five moose samples. EPC is the average value.
Muskrat/Beaver	0.01	0.05	0.21	Based on an average of three beaver and one muskrat samples. Data were combined as concentrations in muskrat sample were similar to those in beaver samples.
Rabbit	0.014	0.095	0.19	Based on an average of two samples collected and combined from three samples from uncontaminated areas in Yellowknife from Koch et al. (2013).
Duck/Goose	0.0017	0.054	0.52	Based on an average of four duck samples and one goose. Data were combined as concentrations in goose sample were similar to those in duck samples.
Ptarmigan/Grouse	0.02	0.12	0.38	Based on an average of eight ptarmigan and one grouse sample. Data was combined as the grouse sample had similar concentrations to the ptarmigan samples and they have a similar diet. Arsenic concentration is based on the geometric mean due to the skewed data set.
Lake whitefish North Yellowknife Bay	0.025	0.21	0.29	Based on 95% UCLM of 30 samples. Antimony concentrations were measured below the detection limit.
Lake whitefish South Yellowknife Bay	0.025	0.18	0.15	Based on 95% UCLM of 20 samples. Antimony concentrations were measured below the detection limit.
Inconnu South Yellowknife Bay	0.025	0.17	0.15	Based on 95% UCLM of 16 samples. Antimony and manganese concentrations were measured below the detection limit.
Lake trout South Yellowknife Bay	0.001	0.18	0.11	Based on average of three samples. Antimony concentrations below the detection limit.
Northern pike North Yellowknife Bay	0.025	0.21	0.3	Based on 95% UCLM of 22 samples. Antimony concentrations were measured below the detection limit. Manganese based on one measured concentration all others below detection limit.
Northern pike South Yellowknife Bay	0.025	0.25	0.35	Based on 95% UCLM of 20 samples. Antimony concentrations were measured below the detection limit.
Berries – Ndilo	0.0073	0.11	16.1	Based on an average of six samples which included three raspberry and three rosehip samples.
Berries – T1 (including Ndilo)	0.0042	0.11	17.5	Based on an average of 14 samples which included three raspberry, three rose hips, six cranberry, one Saskatoon berry, and one bearberry sample.
Berries – Beyond T1	0.0006	0.037	20.2	Based on an average of five samples which includes four cranberry and one raspberry sample.
Labrador tea – Ndilo	0.057	0.61	251.9	Based on an average of two samples. Labrador tea used to represent other medicinal plants (e.g., rat root) as Labrador tea samples had the highest concentrations out of Labrador tea, chives, juniper berry, and spruce gum.
Labrador tea – All areas (including Ndilo)	0.038	0.48	188.1	Based on an average of four samples. Labrador tea used to represent other medicinal plants (e.g., rat root) as Labrador tea samples had the highest concentrations out of Labrador tea, chives, juniper berry, and spruce gum.
Mushroom	See Appendix P			
Organs	0.24	0.02	1.8	Weighted (by ingestion rate) average of moose organs, fish livers, and ptarmigan heart, gizzard, and liver.

Note: T1– location within 10 km of Giant Mine.

Table 3.10 Summary of background concentrations in country foods

Country Food	Background Concentration (mg/kg ww)			Comment
	Antimony	Arsenic	Manganese	
Moose	0.002	0.013	0.28	Based on two moose samples from Behchoko and Francois Bay.
Muskrat/Beaver	0.53	1.1	1.2	Based on one beaver sample from Dry Bones Bay. Two additional background samples result in an arsenic concentration of 0.4 mg/kg ww (see Appendix P).
Rabbit	–	0.01	–	Lowest measured rabbit concentration. No background data for antimony and manganese. Five additional background samples result in an arsenic concentration of 0.008 mg/kg ww (see Appendix P).
Duck/Goose	0.0016	0.03	0.4	Based on one goose and one duck sample.
Ptarmigan/Grouse	0.002	0.004	0.38	Based on an average of three grouse samples.
Lake whitefish	0.025	0.24	0.26	Based on 95% UCLM of 38 samples. Antimony concentrations were measured below the detection limit.
Inconnu	0.025	0.12	0.15	Based on 95% UCLM of 40 samples. Antimony and manganese concentrations were measured below the detection limit.
Lake trout	0.001	0.17	0.17	Based on the average of two samples. Antimony concentrations are below the detection limit.
Northern pike	0.025	0.12	0.15	Based on 95% UCLM of 41 samples. Antimony and manganese concentrations were measured below the detection limit.
Berries	0.0005	0.028	24.4	Based on one cranberry sample from Tibbit Lake. An additional background sample results in an arsenic concentration of 0.021 mg/kg ww (see Appendix P).
Mushroom	0.04	0.13	39	Based on a 95% UCLM of 7 samples reported by Obst (2014). Additional analysis provided in Appendix P.

Note: No background values available for Labrador tea or organs.

The dietary survey indicated that people mainly consume lake whitefish as well as some amounts of inconnu and lake trout. Since the concentrations of antimony, arsenic, and manganese are similar in all three species, it was assumed that the concentrations measured in lake whitefish (the main fish people consume) was representative of all fish.

Appendix P also demonstrates that rat root concentrations are similar to background rat root samples.

3.3.6.2 Locations for Developing Exposure Point Concentrations for Current Scenario

In addition to determining the concentrations in country foods, the risk assessment also needs to consider concentrations in soil, sediment, water, air in the various locations and develop an appropriate exposure concentration. This section discusses the sampling locations and the statistic used to develop the EPCs and Section 3.3.6.4 provides a figure of the EPCS used in the risk assessment.

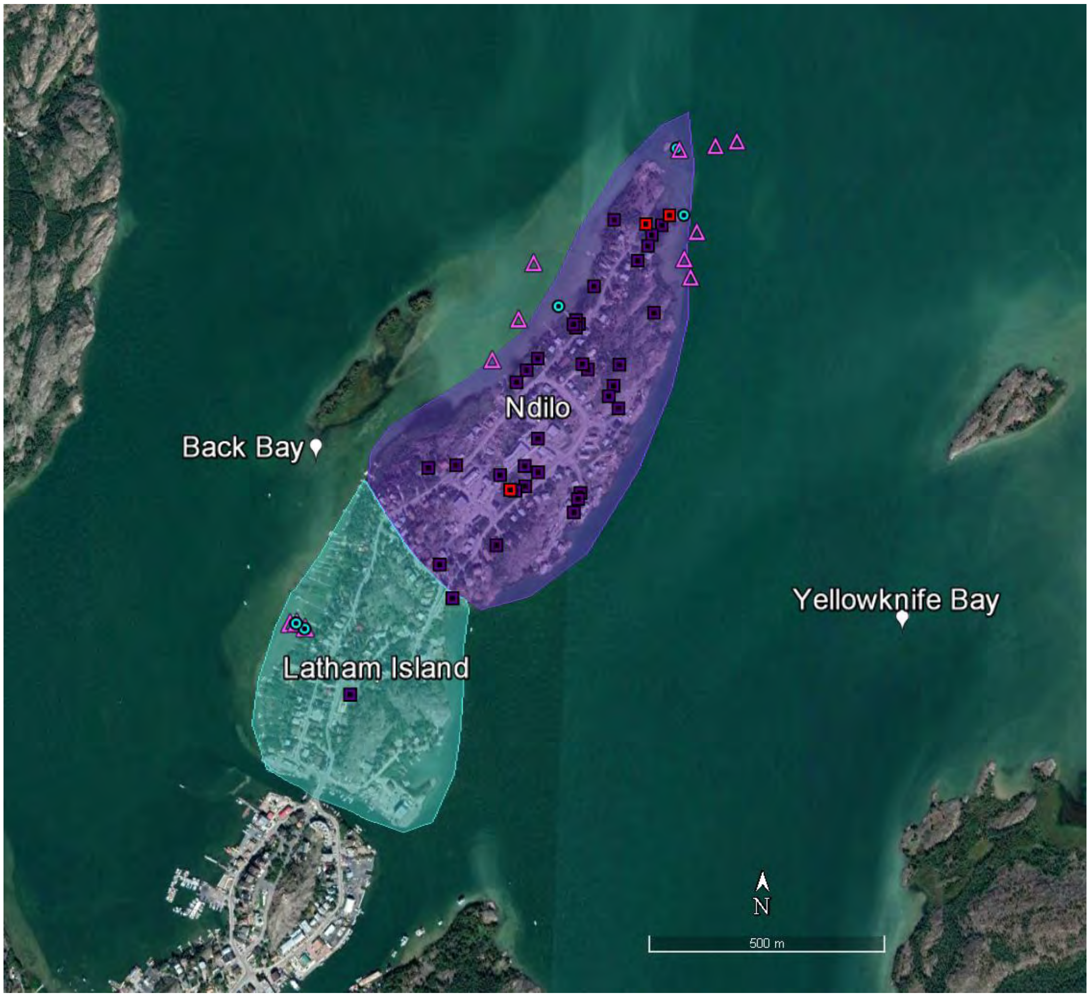
Air quality monitoring in the area has shown that the concentrations in the Yellowknife are similar (see Appendix B) and the values for air concentrations used in the assessment are provided in Appendix F.

Ndilo

The sampling locations for water, soil, and sediments for Ndilo are shown on Figure 3.18. As seen from the figure, there is adequate soil coverage to develop a 95% UCLM to represent exposure. These samples used in the residential scenario include high arsenic concentrations measured in surficial samples to the north end of Ndilo and at the school even though no one lives where these concentrationswere measured. The concentrations of arsenic in the soils are representative of historical contamination from when the Giant Mine was in operation. Similarily, the sediment samples represent a reasonable estimate of the wading scenario. For sediment, the exposure was represented by the maximum concentration. Yellowknife Bay is quite large and the three sampling locations for water are reasonable. It should be noted that the concentrations of arsenic, antimony, and manganese in North Yellowknife Bay are all below Health Canada drinking water guidelines. The scenario that evaluated people drinking from North Yellowknife Bay was represented by a 95% UCLM.

The exposure point concentrations used in the risk assessment are provided in Appendix F.

Figure 3.18 Sampling locations for water, soil, and sediments in Ndilo



There have been several arsenic "hot spots" identified in soils in the community of Ndilo (indicated in red in Figure 3.18 above). A sensitivity analysis was conducted to evaluate the impact of cleaning up the three highest "hot spots" in the Ndilo community.

Latham Island

The sampling locations for water, soil, and sediments for Latham Island are shown on Figure 3.18. As mentioned previously, Latham Island and Ndilo samples were combined to calculate the Latham Island exposure. The sediment samples in Latham Island were specifically collected for the risk assessment to address concerns about children wading at this location. It should be noted that the concentrations of arsenic, antimony, and manganese in Back Bay are all below Health Canada drinking water guidelines. There are enough soil and sediment samples that the 95% UCLM was used to represent exposure.

The scenario that evaluated people drinking from Back Bay was represented by a 95% UCLM. The exposure point concentrations used in the risk assessment are provided in Appendix F.

Dettah

The sampling locations for water, soil, and sediments for Dettah are shown on Figure 3.19. There are only a small number of soil samples available at Dettah, and arsenic was the only COPC measured. The two highest arsenic soil concentrations were from the hill in Dettah and the marina/boat launch. None of these locations are where people live. Thus, a 95% UCLM was developed to represent the residential exposure scenario in Dettah. The water and sediment samples were considered to be adequate to represent the wading scenario and the drinking water scenario. It should be noted that the concentrations of arsenic, antimony, and manganese in South Yellowknife Bay are all below Health Canada drinking water guidelines. The maximum concentration was used to represent the sediment exposure. The exposure point concentrations used in the risk assessment are provided in Appendix F. Two additional soil samples were collected in Dettah as shown in Appendix P.

Figure 3.19 Sampling locations for water, soil, and sediments in Dettah

City of Yellowknife

The sampling locations for soil samples for City of Yellowknife are shown on Figure 3.20. For arsenic, there were a total of 260 soil samples that were used to develop the exposure concentrations. Soil EPCs were represented by the 95% UCLM. The EPCs used in the risk assessment are provided in Appendix F.

In addition to considering the exposure from living in Yellowknife, additional evaluations were carried out related to camping and swimming/wading activities at the Fred Henne Campground and Long Lake. Figure 3.21 shows the location of the soil, water, and sediment locations, and Appendix F provides the exposure concentrations used in the assessment. The arsenic soil concentrations at the Fred Henne Campground are below background and, thus, anyone camping at this location will not experience increased risk. The maximum measured sediment concentration was used to represent the exposure while wading in Long Lake.

Figure 3.20 Soil sampling locations in City of Yellowknife

Figure 3.21 Soil, water, and sediment sampling locations in Fred Henne Campground and Long Lake

Ingraham Trail

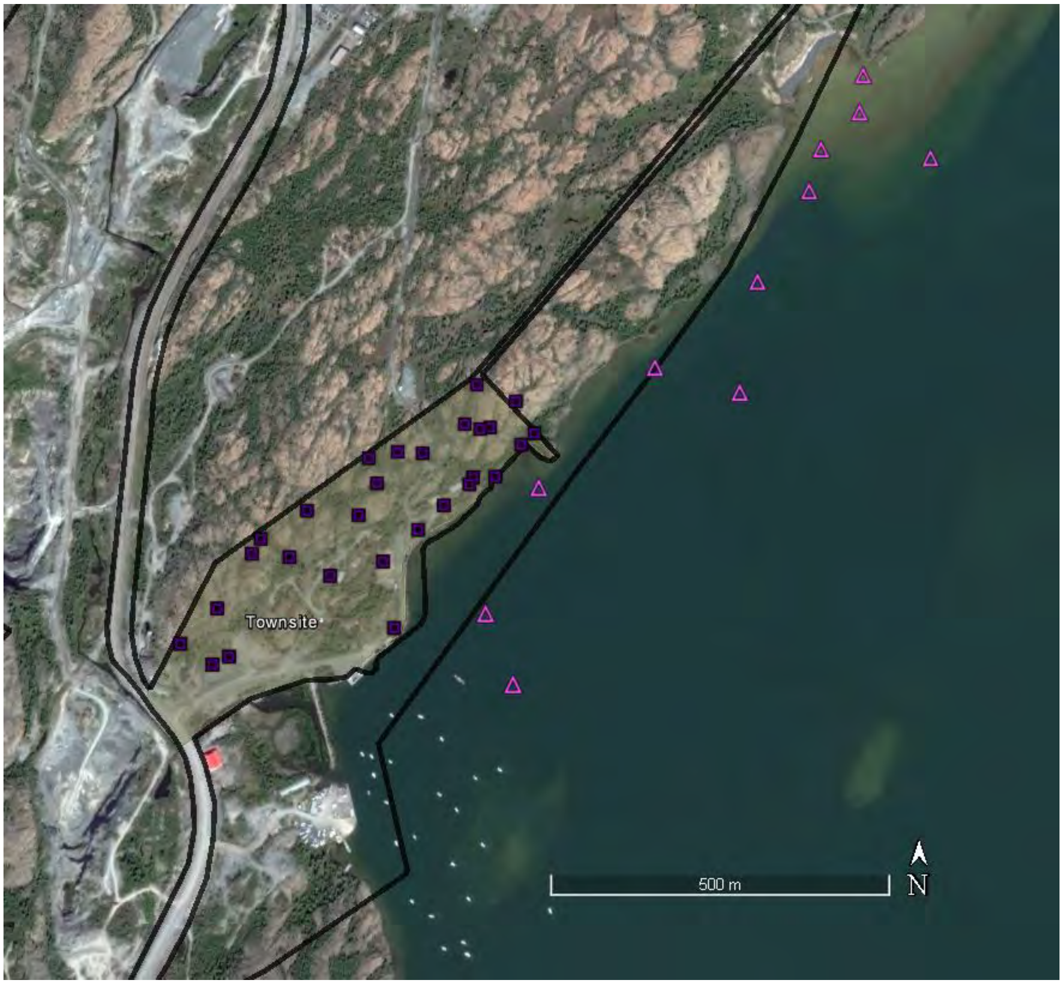
The sampling locations for soil samples for Ingraham Trail near Giant Mine are shown on Figure 3.22. These locations are considered to represent exposures for peopling living along this part of the Trail. The 95th percentile value of the data set was used to represent the residential exposure and represents a conservative estimate. The EPCs for soil used in the risk assessment are provided in Appendix F. Additional soil samples were collected along the Ingraham Trail as part of studies by Queen's University (Jamieson et al. 2017), the locations of which are shown in Appendix P.

Figure 3.22 Soil sampling locations on Ingraham Trail near Giant Mine

Former Townsite

The sampling locations for soil and sediment samples at the former Townsite are shown on Figure 3.23. These samples were used to evaluate the unrealistic scenario that someone would live at this location without any remediation to the soils. The measured sediment samples were used to assess a wading scenario. This wading scenario also accounts for someone currently using the boat launch or the nearby marina, as the sediment concentrations were considered to be representative of conditions in those areas. The 95% UCLM was used to represent exposures at the Townsite.The exposure point concentrations for soil used in the risk assessment are provided in Appendix F.

Figure 3.23 Soil and sediment sampling locations at former Townsite

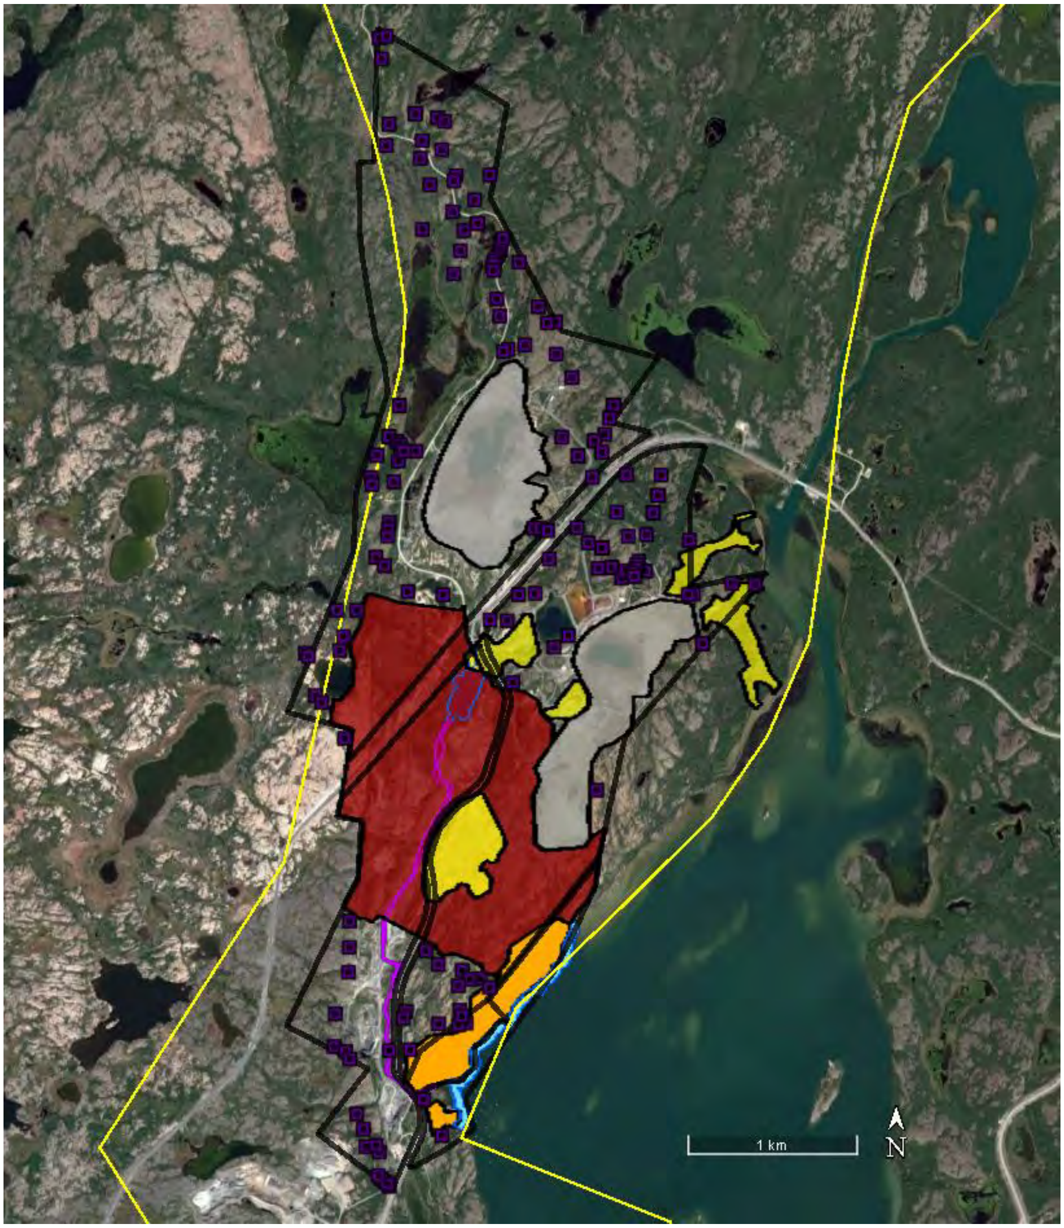


3.3.6.3 Exposure Point Concentrations for Future Scenario

For the former Townsite, the GMRP indicates that arsenic in the soils will be cleaned up to the GNWT residential criterion of 160 mg/kg. Soil remedial objectives have not been established for antimony and manganese and, thus, assumptions were made as to what the future concentrations will be. It is noted that antimony and arsenic concentrations are generally located together. Based on the measured soil data at two locations in the former Townsite where the arsenic concentrations are close to the GNWT residential criterion (YK126 and YK302), the antimony soil concentrations are about 10% of the arsenic soil concentrations, and manganese soil concentrations are approximately 40% higher than arsenic soil concentrations. Therefore, in the future after remediation, the antimony concentrations at the former Townsite are assumed to be 16 mg/kg and the manganese concentrations 220 mg/kg. For sediments, the GMRP indicates that dredging will occur in the shoreline sediments along the Townsite and near the mouth of Baker Creek. Deeper sediments will be covered. It is assumed that arsenic concentrations in this dredged area would be approximately 30 mg/kg based on the post remediation concentrations of arsenic in sediments in Reach 0 of Baker Creek. This concentration was recorded in native sediment/soil at Reach 0.

A recreational scenario was also considered for people going onto the remediated Giant Mine in the future for exercise or other recreational activities. It is recognized that members of the YKDFN community do not want to use the Giant Mine in the future; however, other stakeholders have indicated that they want to use the Giant Mine. In order to determine the future concentrations of arsenic, antimony, and manganese in the soil on Giant Mine, the remedial activities on the site were taken into account. Figure 3.24 shows the samples considered in deriving the concentrations at the Giant Mine in the future. For the future scenario, it was assumed that people will not be able to go into the red area on the map, as this area has arsenic concentrations over 3,000 mg/kg and will be actively managed in the form of excavation and/or fencing. The yellow areas in the figure on the Giant Mine within the lease boundary were assumed to be remediated to an arsenic concentration of 340 mg/kg. The tailings were assumed to be covered with rock and to not represent any potential for exposure. No remedial criteria have been developed for antimony and manganese; thus, the future conditions were based on all of the samples shown on Figure 3.24. The approach is discussed in more detail in Appendix F and the EPCs are provided. The EPCs derived represent an overestimate of potential exposure as there are parts of the site that are heavily forested and have wetlands that cannot easily be easily accessed.

Figure 3.24 Samples considered in deriving future concentrations for HHRA for Giant Mine



Note: Thick black line around coloured areas represent the lease boundary. Yellow lines denote the Yellowknife Greenstone Belt.
Yellow areas inside the lease boundary represent the disturbed areas; arsenic to be remediated to GNWT industrial criterion.
Red area represents area where the arsenic in soils exceeds 3000 mg/kg.
Grey areas represent tailings ponds.
Orange areas at bottom of picture represent the former Townsite and marina; arsenic in Townsite to be remediated to GNWT residential criterion.
Yellow areas outside boundary of East Baker creek are the tailings spills.
Baker creek (shown in purple), Baker Pond (outlined in blue), and the near-shore Townsite sediments (shown in light blue) are areas identified for sediment remediation.

3.3.6.4 Summary of Water, Soil, Sediment, and Indoor Dust EPCs

Figure 3.25 provides a figure showing the EPCs used in the risk assessment for water. For the risk assessment it was assumed that everyone used the municipal water supply. For some of the scenarios, it was assumed that people may get water from different parts of Yellowknife Bay (Back Bay, North Yellowknife Bay and South Yellowknife Bay). Background EPCs are also included. As seen in the figure, the water concentrations in Yellowknife Bay are similar to the municipal supply.

Figure 3.25 Exposure point concentrations for water

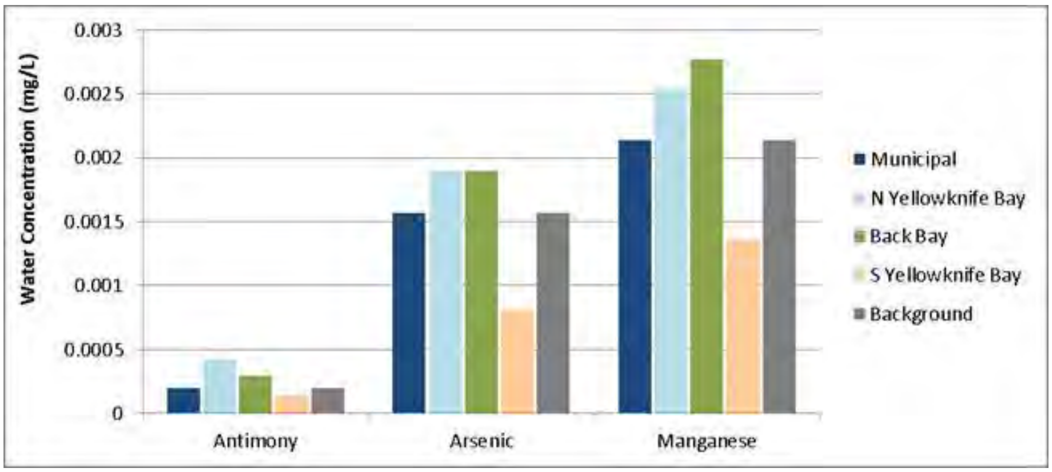


Figure 3.26 provides a figure showing the EPCs used in the risk assessment for soil, sediment, and indoor dust by location. Background EPCs are also included. Appendix P indicates that the two extra soil samples in Dettah result in lower concentrations that those shown in Figure 3.26 and therefore the assessment presented is conservative. Similarly the 16 additional samples along the Ingraham Trail also result in lower concentrations than those shown in Figure 3.26.

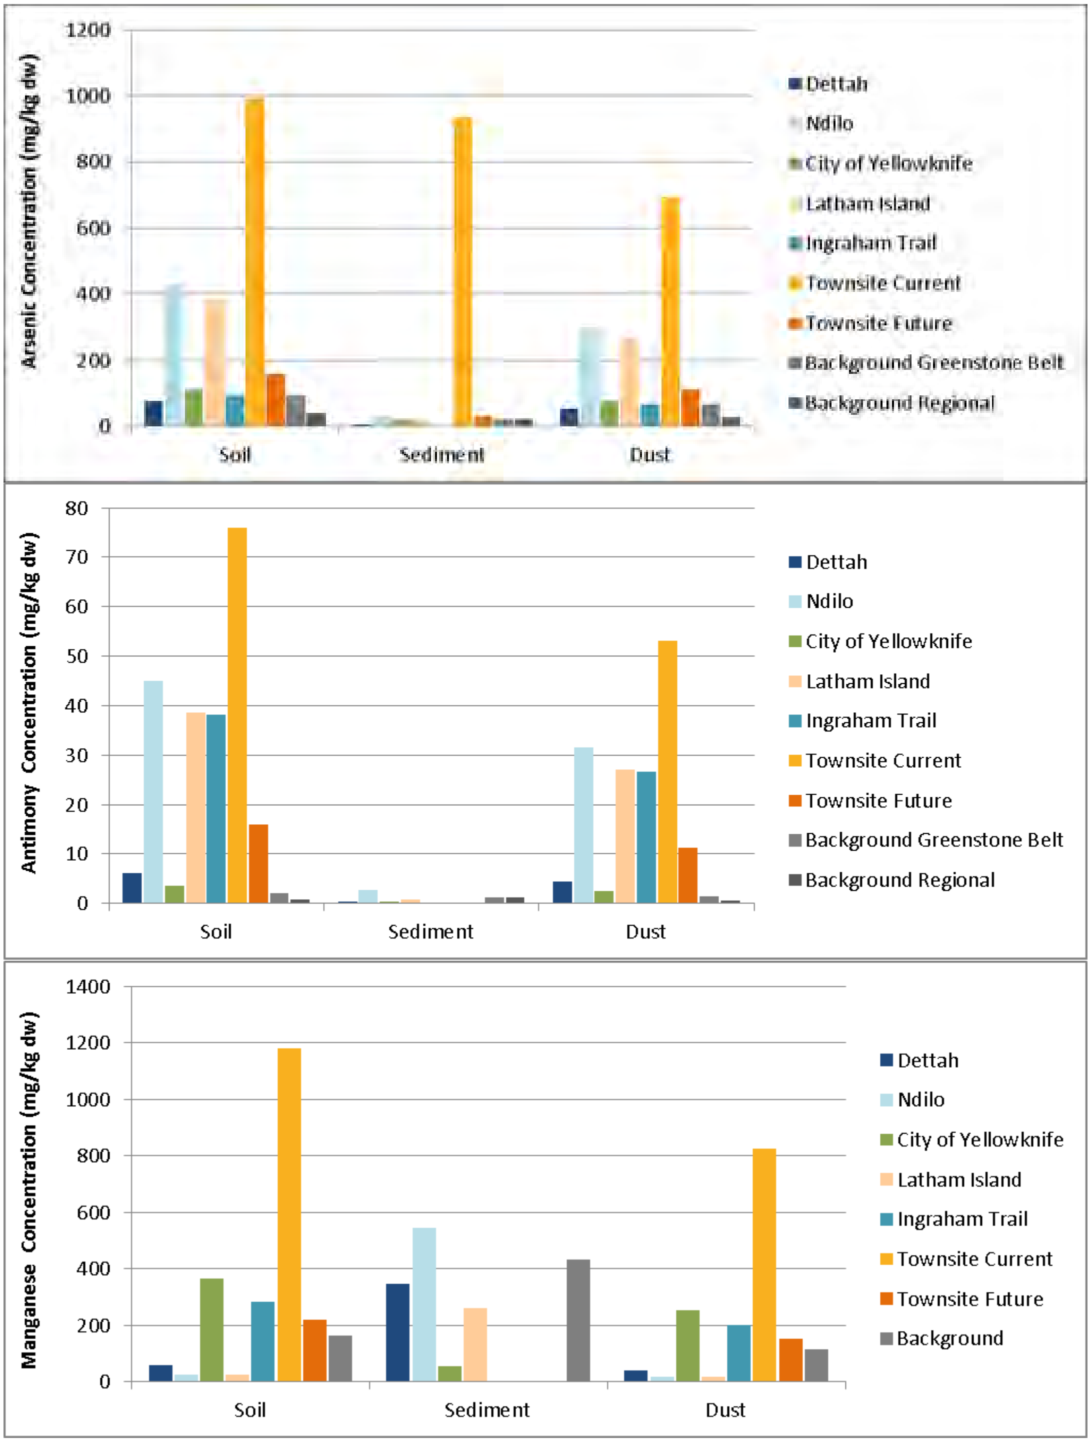
Figure 3.26 Selected exposure point concentrations for soil, sediment, and indoor dust



3.3.7 Exposure Estimation

The exposure assessment uses all of the available information collected about people and the measured concentrations of antimony, arsenic, and manganese in air, water, soil, sediments, dust, supermarket foods, and country foods to estimate the total exposure (intake) of antimony, arsenic, and manganese to people (toddlers, children, teens, adults, and elders).

Exposures from air, water, soil, sediments, dust, supermarket foods, and country foods for each route of exposure (eating, breathing, skin contact) were calculated using equations provided by Health Canada (2012a). These equations are provided in Appendix E. The HHRA considers long term exposures; background exposures were taken into account in the exposure estimates. Averaging periods were considered to be consistent with exposure periods; for example, the exposure for someone wading was considered for ten weeks duration and not averaged over an entire year.

3.3.7.1 Sensitivity Assessment

A number of assumptions have gone into the risk assessment in order to evaluate realistic, yet conservative, estimates of exposure. A few sensitivity assessments were carried out to see the effect of some of these assumptions on the results.

The first sensitivity analysis was related to country food concentrations. An average value for the samples was used to reflect what people would eat food from a wide variety of areas. To determine whether this assumption was realistic or not and would result in a substantial change in the results, a sensitivity assessment was completed using the maximum measured concentrations for the country foods.

In the risk assessment, it was assumed that 5% of berries for the people living in Ndilo came from the community, to account for the fact that children have reported eating berries from bushes around Ndilo. Although it is unlikely to occur since there are not enough berry bushes to support this, a sensitivity assessment was completed to evaluate the consumption of 100% of berries from Ndilo.

One moose sample obtained from the voluntary sampling had an arsenic level of 0.7 mg/kg ww and was determined to be an outlier. In addition, the concentration of arsenic in moose liver collected from the area is much lower than this measured concentration. However, since moose represents the most consumed meat from the 2017

Dietary Survey Update and to ensure that potential risks were not being misrepresented, a sensitivity assessment was completed using the arsenic concentration of 0.65 mg/kg ww from this moose sample.

The concentration or arsenic in ptarmigan was an order of magnitude higher than concentrations measured in background (0.02 mg/kg ww vs. 0.004 mg/kg ww). Therefore, the sensitivity analysis considered that ptarmigan/grouse made up all the wild game that people consume.

Although the assumption of indoor dust equal to 70% outdoor soil concentrations is an accepted practice, a sensitivity assessment was completed to address the uncertainty around this assumption. An assessment was completed to illustrate the potential exposures assuming that indoor dust is equal to (or 100% of) outdoor soil concentrations.

An additional uncertainty involved the arsenic bioaccessibility from consumed animal tissues (meat). A value of 50% was used based on the measurements in hare in Yellowknife from a study by Koch et al. (2013). The sensitivity assessment looked at the consideration of 100% bioaccessibility of arsenic in animals even though it is well known that arsenic in food samples are not 100% available.

There have been several “hot spots” identified in soils in the community of Ndilo to the north of the area and at the school. The sensitivity analysis evaluated the impact of cleaning up the three highest “hot spots” in the Ndilo community.

It is very difficult to quantify the effects of climate change in the future. In the DAR (INAC/GNWT 2010), the Canadian Climate Change Scenarios Network (CCCSN) assessment indicated that precipitation may increase by up to 15% over the next 50 years. As the future assessment was evaluating a 100 year scenario, it was assumed the change in precipitation could be as high as 30%. The increased precipitation could lead to increased run-off and soil erosion and thus concentrations in the environment could increase. In an attempt to evaluate this effect, the sensitivity assessment looked at the effect of increasing the water and sediment concentrations and, consequently, fish concentrations by 30%.

3.3.8 Summary of Exposure Assessment

For the HHRA, intakes of arsenic, antimony, and manganese were estimated using the exposure assumptions outlined above. Figure 3.27 presents a summary of the estimated intakes for arsenic for the typical country food diet receptor from Ndilo. This figure illustrates that the toddler is the most highly exposed life stage in the HHRA. Therefore, for presentation purposes, the estimated intakes for toddlers under the base case scenarios are provided in Figure 3.28, Figure 3.30, and Figure 3.31 for total arsenic, antimony, and manganese, respectively. Estimated intakes for all life stages and scenarios are provided in Appendix F.

Figure 3.27 Estimated total arsenic intakes for Ndilo country food scenario

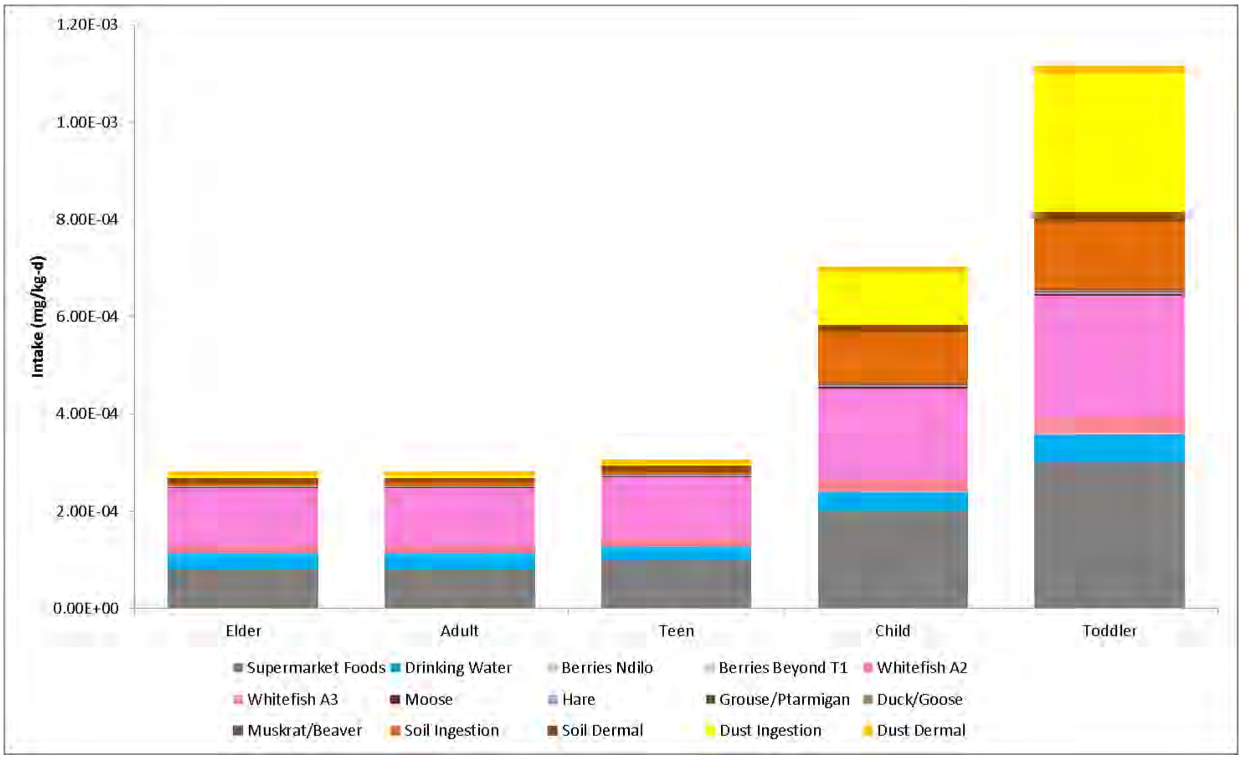


Figure 3.28 shows that, after supermarket foods, toddlers are most exposed to arsenic in fish, with soil, indoor dust, and drinking water also contributing to the total intake for arsenic. Intakes to indoor dust and soil vary depending on the receptor location, as arsenic concentrations in soil vary by location. There is some double-counting for the total arsenic intakes presented in Figure 3.28, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods. Estimated intakes for all life stages and scenarios are provided in Appendix F.

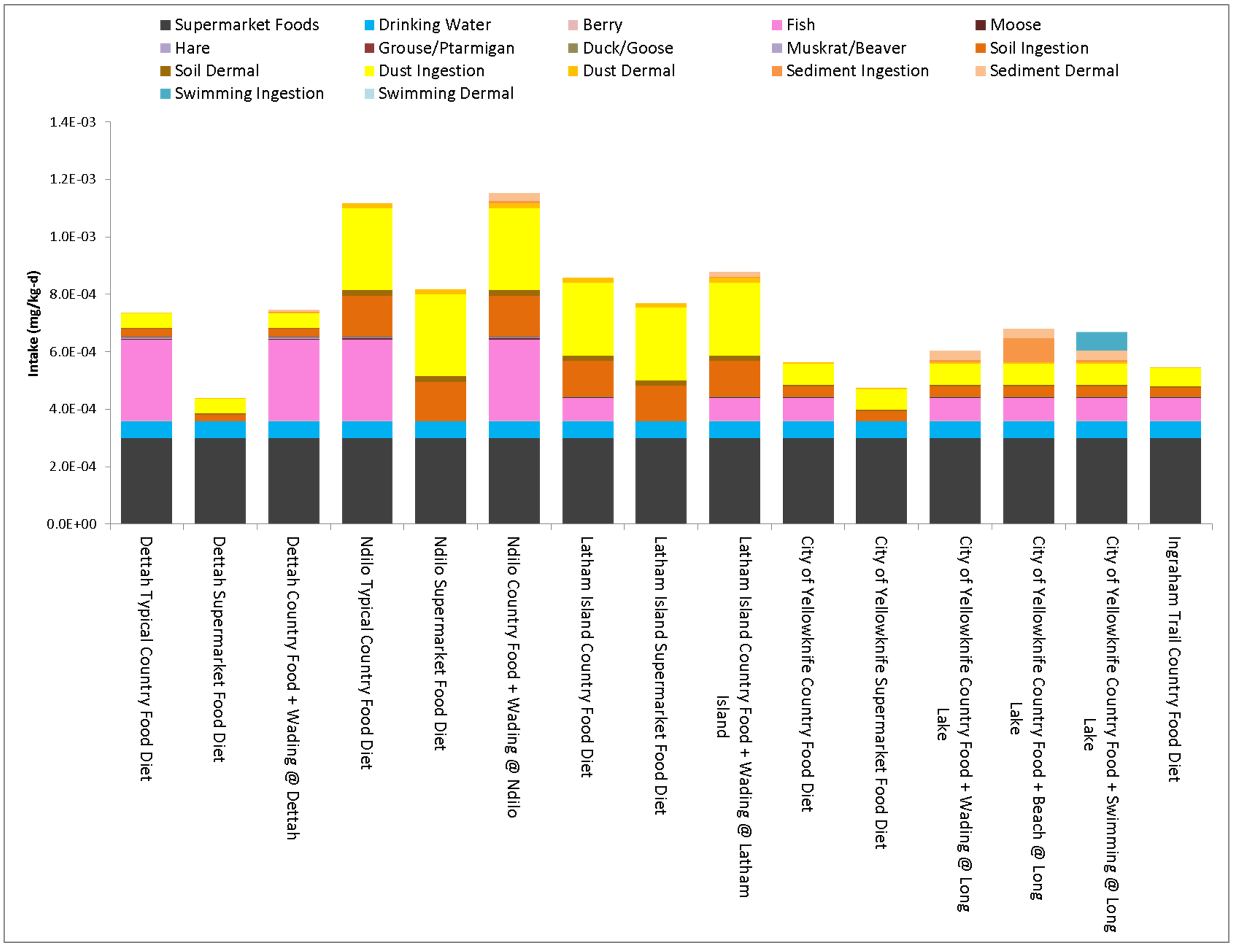
Figure 3.28 Estimated intakes for toddler – total arsenic



Because arsenic is evaluated on an incremental basis, Figure 3.29 is provided to illustrate the relevant pathways of exposure for incremental arsenic exposure. The incremental arsenic exposure is obtained by subtracting estimated intakes for background arsenic exposure (Figure 3.32) from the total arsenic intake (Figure 3.28). Figure 3.29 shows that, since a number of the country foods (such as fish) are at background arsenic concentrations, food pathways contribute marginally to the overall incremental intake of arsenic. Thus, exposures from indoor household dust and soil, through both ingestion and, to a lesser extent, skin contact, dominate the intakes of incremental arsenic by the toddler receptor. These exposures are a result of historical contamination across the Yellowknife area. For the wading or beach scenarios, dermal contact with sediment is shown to contribute to the intake of incremental arsenic, as does swallowing water while swimming at Long Lake. These exposures will not be altered by any of the remedial activities at the Giant Mine.

Figure 3.29 Estimated intakes for toddler – incremental arsenic

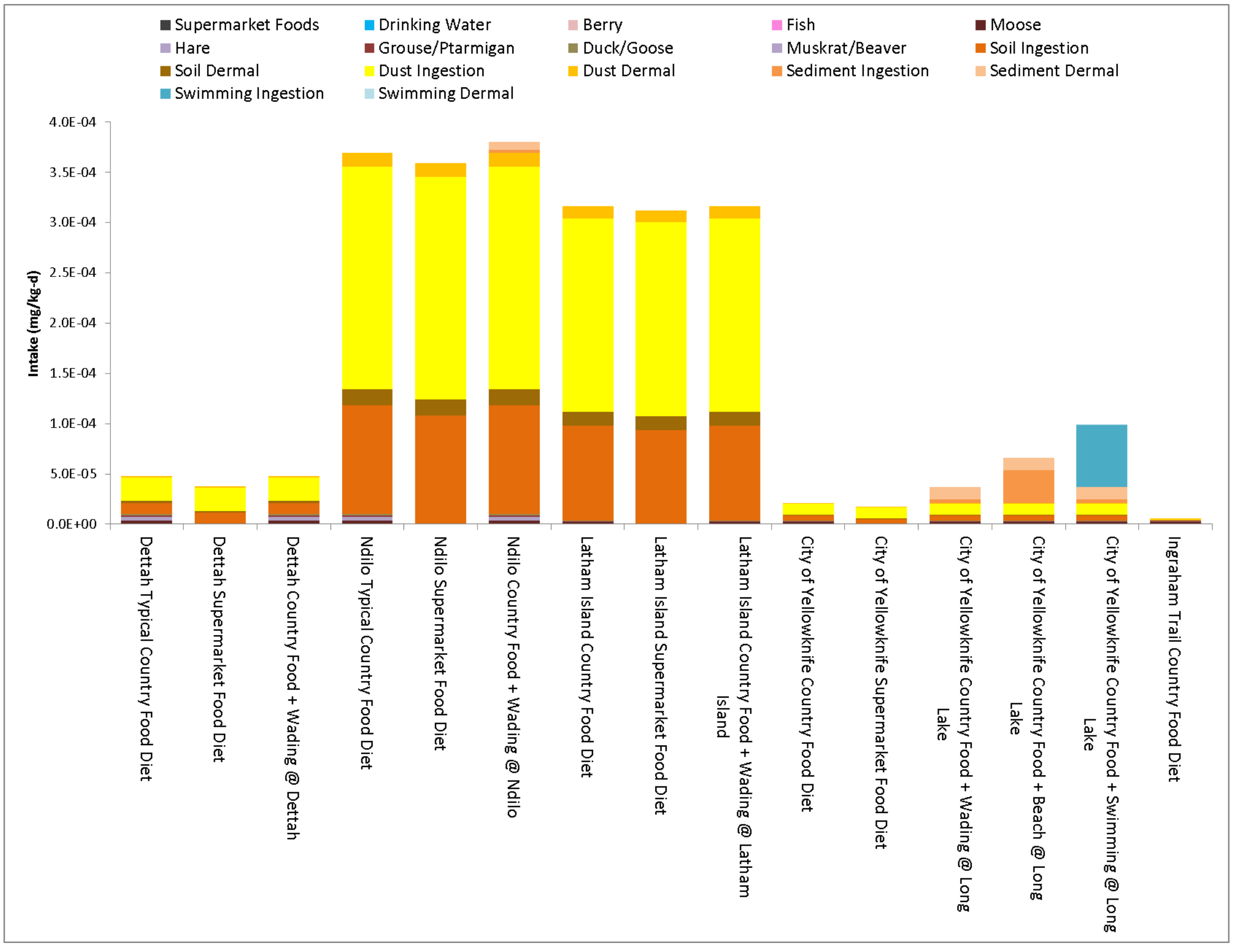


Figure 3.30 shows that, after supermarket foods, fish represents the next largest exposure to antimony for toddlers. For some locations, antimony in soil and indoor dust contributes to the total exposure via the ingestion and skin contact pathways. There is some double-counting for the antimony intakes presented in Figure 3.30, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods. Estimated intakes for all life stages and scenarios are provided in Appendix F.

Figure 3.30 Estimated intakes for toddler – antimony

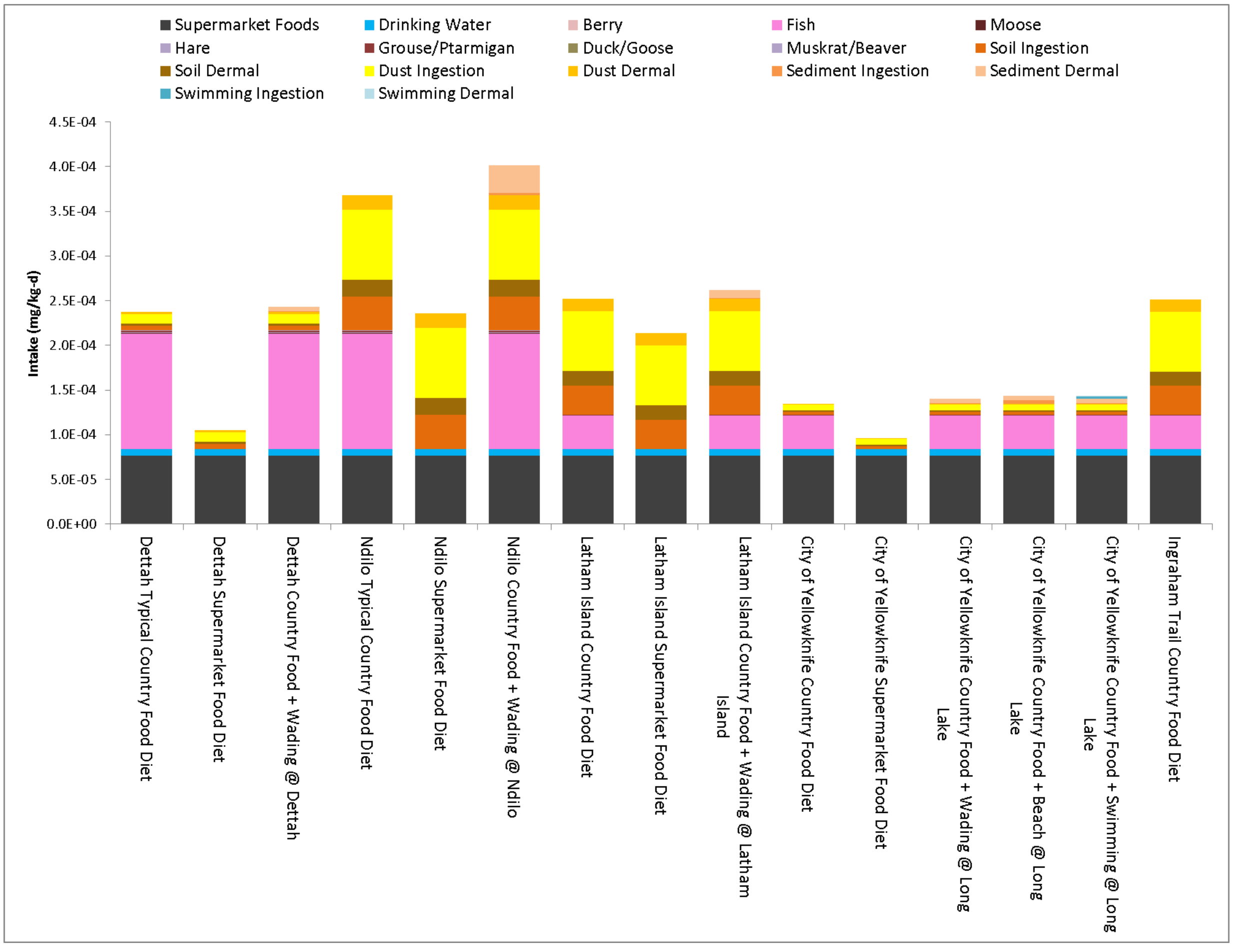

Figure 3.31 shows that supermarket foods contribute almost completely to the total intake of manganese for toddlers. Other pathways such as drinking water, air, country foods, soil, and indoor dust are essentially negligible compared with supermarket food intakes. There is some double-counting for the manganese intakes presented in Figure 3.31, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods. Estimated intakes for all life stages and scenarios are provided in Appendix F.

Figure 3.31 Estimated intakes for toddler – manganese

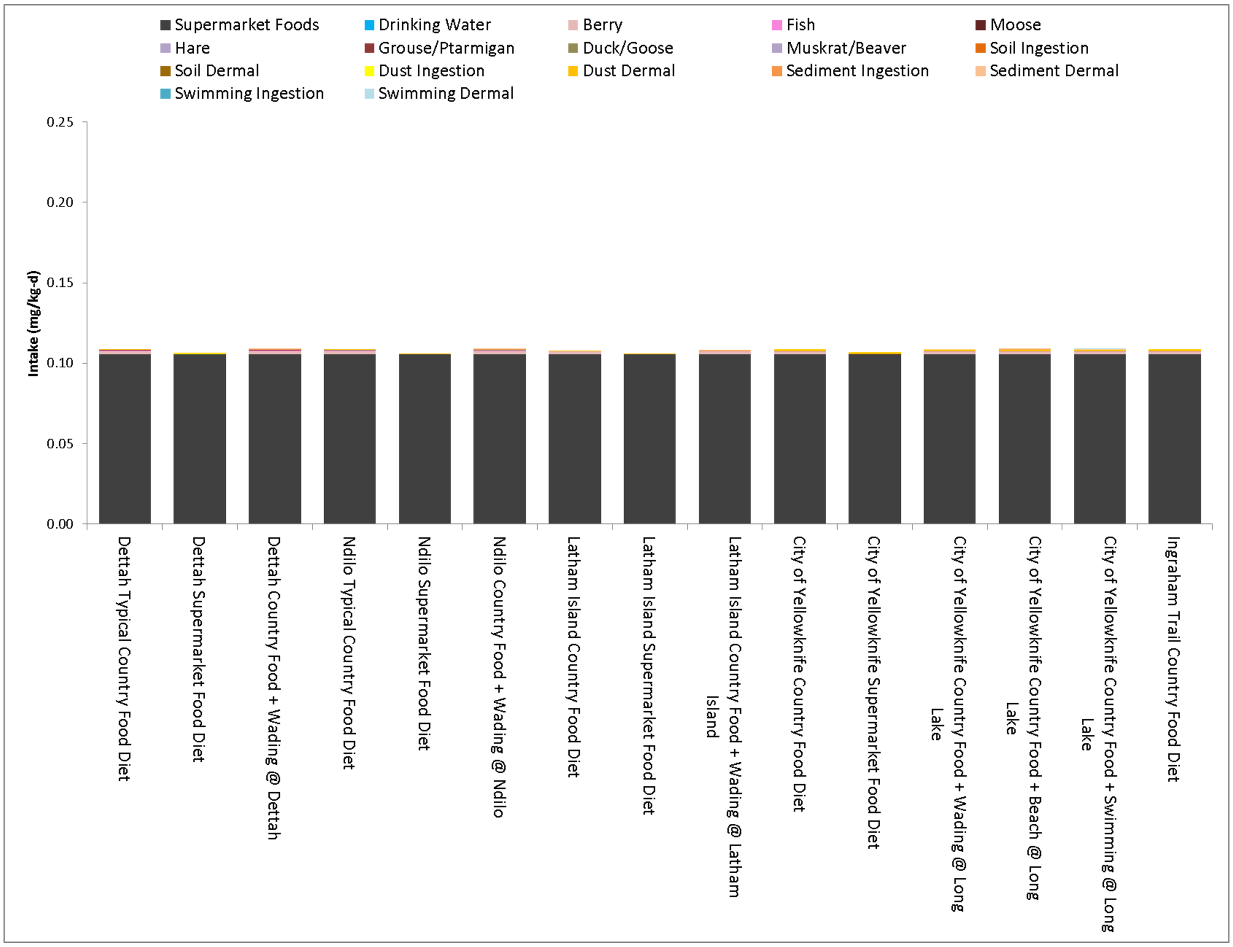

Figure 3.32 shows representative intakes associated with background exposures for all pathways and the five life stages considered in the HHRA for total arsenic, antimony, and manganese. Intakes for total arsenic from background are dominated by the intake of arsenic in fish and supermarket foods, and, to a lesser extent, drinking water. Background exposures to antimony are similarly dominated by intakes from fish and supermarket foods, and, to a lesser extent, muskrat/beaver. Background exposures to manganese are dominated by the intake of manganese in supermarket foods.

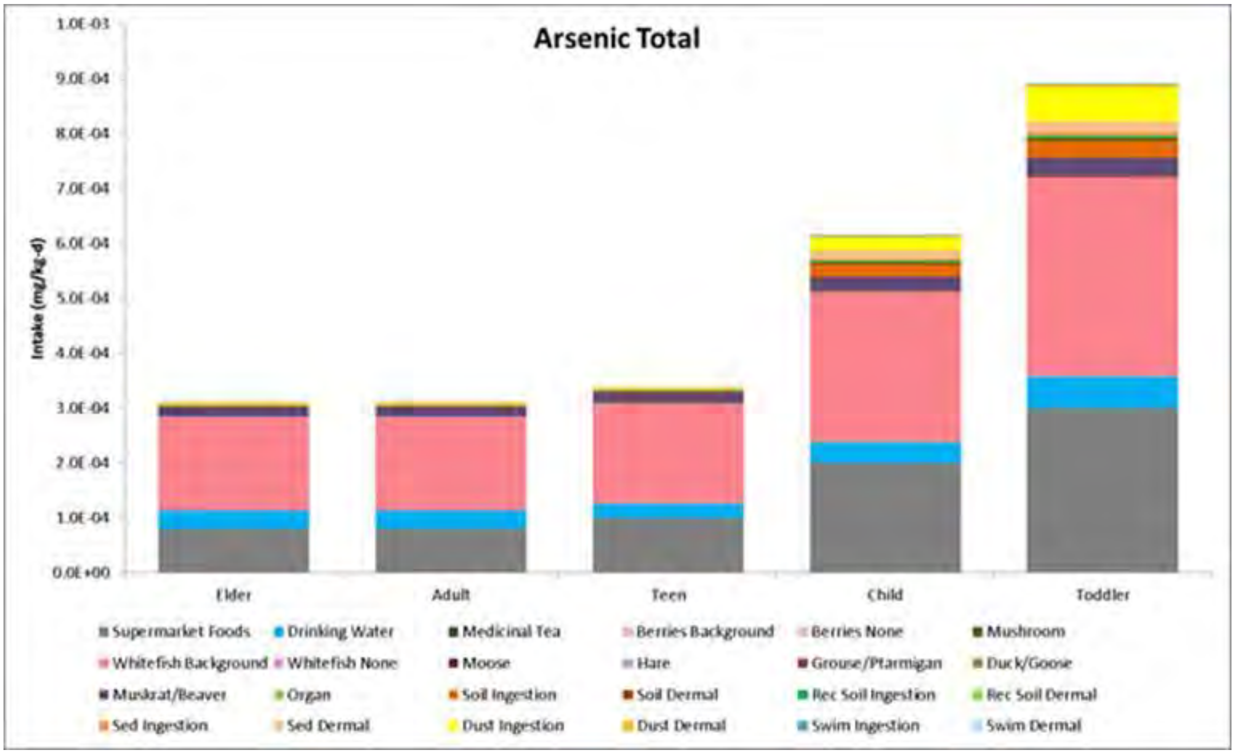
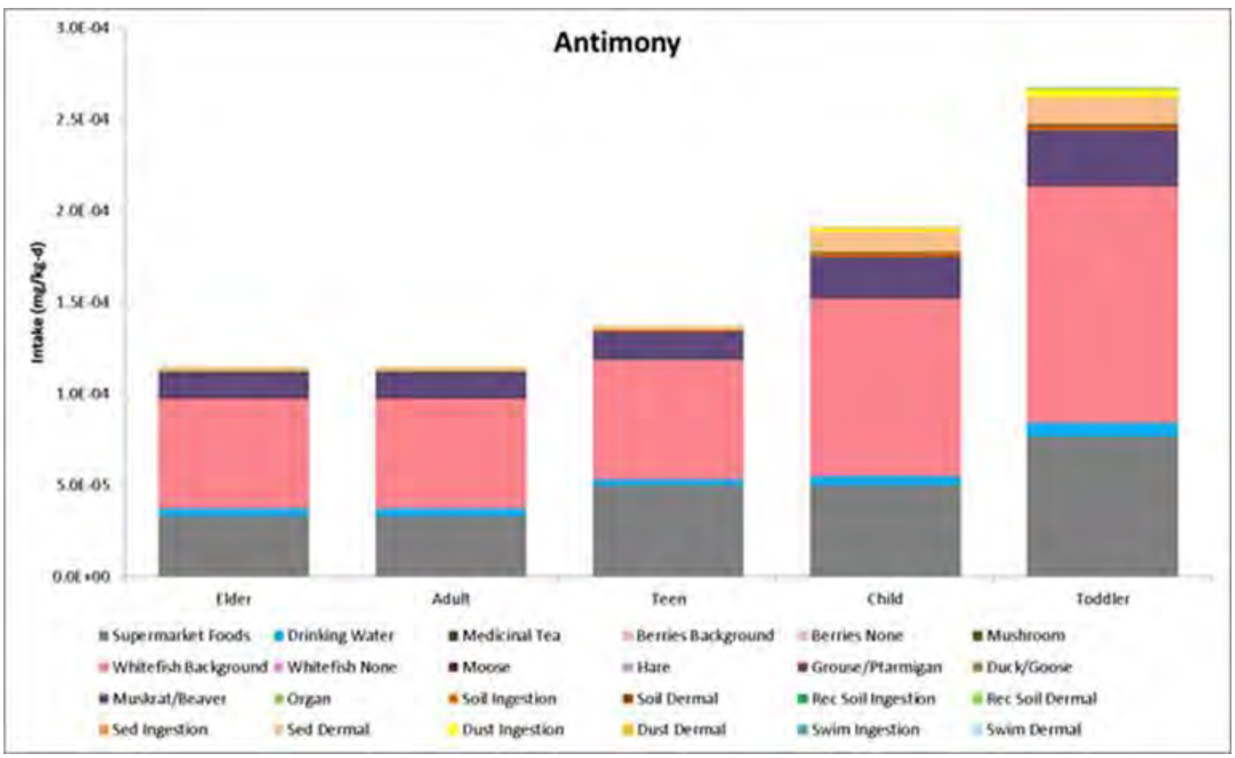
Background exposures are, in some cases, underestimated due to a lack of available data. Background air concentrations for antimony and manganese were assumed to be zero in the absence of other information. Similarly, there were no data to determine the background concentrations of antimony and manganese in hare and organs. There are no background arsenic exposures for organs.

Figure 3.32 Estimated intakes for background for all exposure pathways





3.4 Toxicity Assessment

Toxicity refers to the ability of a chemical to cause temporary or permanent adverse effects in the body. Toxicity depends on several factors such as the form of the chemical, the amount of exposure, and the duration of the exposure.

For some chemicals that do not cause cancer, there is a permissible (safe) level or threshold dose below which adverse health effects are not expected to occur. These permissible levels are set by regulatory agencies such as Health Canada and the U.S. EPA based on scientific studies from laboratory animal tests or on human epidemiological studies or workplace exposure investigations. These studies are reviewed by a number of experienced scientists in a wide range of scientific disciplines in order to determine the maximum dose that a human can be exposed to without having an adverse health effect. Permissible doses are usually reported as the amount of chemical per unit body weight per unit time that a person may be exposed to every day of their entire life that will not cause adverse health effects. For example, the oral (eating/swallowing) permissible dose for manganese for a toddler used in this study was 136 micrograms per kilogram of body weight per day. It should be noted that exposure above a permissible level does not mean that an effect will occur, but instead means that there is an increased risk of an adverse effect occurring.

Arsenic is known to cause cancer. For chemicals that cause cancer, the total exposure over an entire lifespan (from birth to death) is calculated using a lifetime receptor, which represents a combination of all life stages (infant, toddler, child, adolescent, and adult). This is because before a cancer occurs, a person needs to be exposed for a very long time to arsenic before an adverse effect is observed. The exposure calculated for the lifetime receptor is known as the lifetime average daily dose. The cancer-causing power of a carcinogen is represented by its cancer slope factor. These are values set by regulatory agencies such as Health Canada and the U.S. EPA based on specially designed cancer studies in humans or laboratory animals. Cancer slope factors are used in combination with the average lifetime exposure estimates for carcinogens to estimate cancer risks.

Toxicity Reference Values (TRVs) are intended to protect the most sensitive individuals (e.g., the elderly, pregnant women, children, etc.) as well as people with compromised health such as asthmatics.

The COPC considered for the human health assessment are arsenic, antimony, and manganese. Antimony and manganese are not considered to cause cancer. Arsenic, however, is considered carcinogenic. Table 3.11 provides a summary of the TRVs selected for use in the assessment for oral exposure. The TRVs are all obtained from Health Canada (2010b) with the exception of antimony where the TRV is obtained from the U.S. EPA Integrated Risk Information System (IRIS) database (U.S. EPA 2017). The TRVs, health effects (toxicological endpoints), and reference sources for each TRV are provided in the table. The following sections provide a brief discussion of the toxicity of the three selected COPC. TRVs for the dermal exposure pathway are not generally available. Therefore dermal exposures are generally added to the ingestion exposures once adjustments are made to account for differences in absorption (see Appendix F and Table 3.6).

A more detailed discussion of the toxicity of these COPC is provided in Appendix G.

Table 3.11 Summary of toxicity reference values for humans

COPC	Oral Toxicity Reference Value					Inhalation Toxicity Reference Value				
	Carcinogenic		Non-Carcinogenic		Endpoint	Carcinogenic		Non-Carcinogenic		Endpoint
	$(mg/(kg\text{-}d))^{-1}$		(mg/(kg-d))			$(mg/m^3)^{-1}$		(mg/m^3)		
Antimony	N/A		$4.0\text{x}10^{-4}$	U.S. EPA (2017; last updated 1991)	Longevity, blood glucose and cholesterol	N/A		N/A	N/A	–
Arsenic	1.8	Health Canada (2010b)	N/A		Internal cancers	6.4	Health Canada (2010b)	N/A		Lung cancer
Manganese	N/A		0.136 (toddler) 0.122 (child) 0.142 (teen) 0.156 (adult)	Health Canada (2010b)	Neuro-toxicity	N/A		$5.0\text{x}10^{-5}$	U.S. EPA (2017; last updated 1996)	Impairment of neuro-behavioural function

N/A: Not applicable.
For antimony, the only inhalation TRV available is for antimony that is not considered the appropriate form of antimony in air in Yellowknife.
There are no TRVs for dermal exposures; dermal exposures are added to oral exposures after adjustments made for absorption.

3.4.1 Cancer-Causing Contaminants

Arsenic is the only COPC identified that is considered to cause cancer. The Agency for Toxic Substances and Disease Registry (ATSDR 2017) provides a detailed discussion of the various toxicity endpoints for arsenic. The focus of this discussion and the discussion in Appendix G is on the endpoints used by regulatory agencies for TRVs.

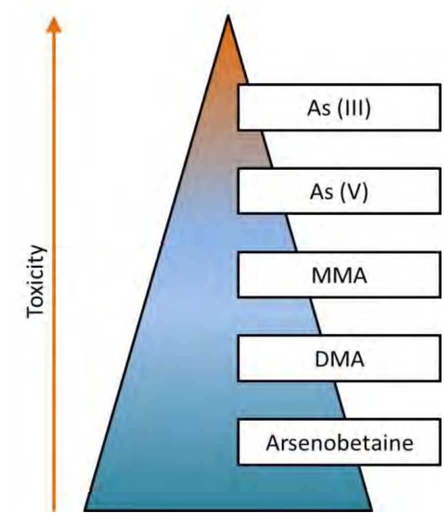
3.4.1.1 Arsenic

Trivalent arsenic (As^{3+}) is generally more toxic than pentavalent arsenic (As^{5+}). The problem with arsenic toxicity is the formation of by-products of oxidation of arsenate, such as arsenite, MMA, and DMA that do not allow for a clear dose-response curve. While the methylation of arsenate helps in the removal of arsenic from the body, it has been shown to increase the levels of these three toxicants.

Research has shown that all four forms of arsenic (As^{3+}, As^{5+}, DMA, MMA) have adverse effects at the cell metabolism level by damaging cell DNA or by reacting with critical sulfhydryl containing enzymes; however, it is unclear how to correlate data obtained from animal studies to actual human effects (Hughes et al. 2011). Organic arsenic compounds such as arsenobetaine are found in fish and shellfish and are considered not to be toxic.

Figure 3.33 shows a schematic of the relative toxicities of the arsenic species. Due to the fact that there are no definitive dose response curves for the various arsenic species As^{3+}, As^{5+}, DMA, MMA, they have all been assumed to have the same toxicity as As^{3+}. Arsenobetaine has been assumed to be non-toxic.

Figure 3.33 Schematic of the relative toxicities of arsenic species



Arsenic is considered to cause cancer in the lung, bladder, and skin as discussed in Appendix G. An oral slope factor of 1.8 $(mg/kg\ d)^{-1}$ and an inhalation unit risk of 6.4 per (mg/m^3) derived by Health Canada (2010b) is used in this assessment. The IRIS database (U.S. EPA 2017) provides an oral slope factor of 1.8 $(mg/kg\ d)^{-1}$ (see Appendix G). The effect of using this oral slope factor is discussed in the Uncertainty section (see Section 3.5.4). No TRVs for non-carcinogenic endpoints are provided in Health Canada (2010b). More details on the selection of these values are provided in Appendix G.

3.4.2 Non-Cancer-Causing Contaminants

Antimony and manganese are not considered to cause cancer.

3.4.2.1 Antimony

Antimony toxicity occurs either from exposure in the workplace or during therapy. Workplace exposure may cause irritation in the respiratory system, lung disease, antimony spots on the skin, and problems with digestion. The critical effects for exposure to antimony include effects on longevity, blood glucose, and cholesterol levels.

Health Canada (2010b) has no published TRVs for antimony. The IRIS database (U.S. EPA 2017) provides an oral TRV of 0.0004 mg/kg-d, which is based on a study in rats. This value includes a safety factor of 1,000. This value was used in the assessment and more details on antimony toxicity and the selection of the TRVs is provided in Appendix G. There are more recent evaluations of the toxicity of antimony by the WHO and other international regulatory agencies, based on their evaluations a TRV of 0.006 mg/kg-d has been derived (see Appendix G). The effect of using this antimony TRV is discussed in the Uncertainty section (see Section 3.5.4). The only TRV for inhalation is based on antimony trioxide, which is not the form or antimony found in the air and thus was not considered.

3.4.2.2 Manganese

Manganese is essential for normal functioning of cells in the body. Several diseases in humans have been associated with either excess or a lack of manganese in the diet. Most toxic effects have been observed in workers and are generally related to breathing in high concentrations of manganese. The toxicity information on oral exposures is related to safe dietary intakes.

Health Canada (2010b) derived oral TRVs for different life stages of 0.136 mg/kg-d, 0.122 mg/kg-d, 0.142 mg/kg-d, and 0.156 mg/kg-d for infants and toddlers, children, teens, and adults, respectively. The IRIS database (U.S. EPA 2017) provides an inhalation TRV of 0.00005 mg/m^3 based on exposure in the workplace using a safety factor of 1,000. These values were used in the assessment and more details on manganese toxicity and the selection of the TRVs is provided in Appendix G.

3.4.3 Evaluation of Potential Toxic Interactions

There are very few methods for combining exposures to multiple COPC at a regulatory level. The simple approach to multiple chemical exposures involves the use of individual toxicities and adding the exposures if the end points are for the same target cell or tissue. As seen from Table 3.11, the various endpoints are very different for exposures of arsenic, antimony, and manganese, and, thus, there is a very low possibility of toxic interactions.

3.5 Risk Characterization

The results of the risk characterization for the HHRA are provided in the following sections; more detailed results are provided in Appendix H, including the sensitivity analyses. Appendix I provides the sample calculations.

3.5.1 Non-Cancer-Causing Chemicals

Antimony and manganese are determined not to cause cancer. The risk for these chemicals is determined by comparing the calculated exposure estimates to the Permissible dose or safe level. When the calculated exposure is below the safe level, adverse health effects are not expected. In this case, risks may be considered to be insignificant or negligible. If the calculated exposure estimate exceeds the safe level, then the risk of an adverse health effect cannot be ruled out.

3.5.1.1 Estimation of Risk – Current Scenario

The toddler is typically the most exposed receptor due to lower body weight and generally higher relative exposures to soil and sediment. Therefore, results for the toddler at all locations are presented in the following sections to represent the highest estimated exposures for antimony and manganese. In addition, results for an elder are provided as they are considered a sensitive life stage. Complete results for all life stages, including a breakdown by exposure pathway, are provided in Appendix H; sample calculations are provided in Appendix I.

Typical Diet Scenarios

Antimony

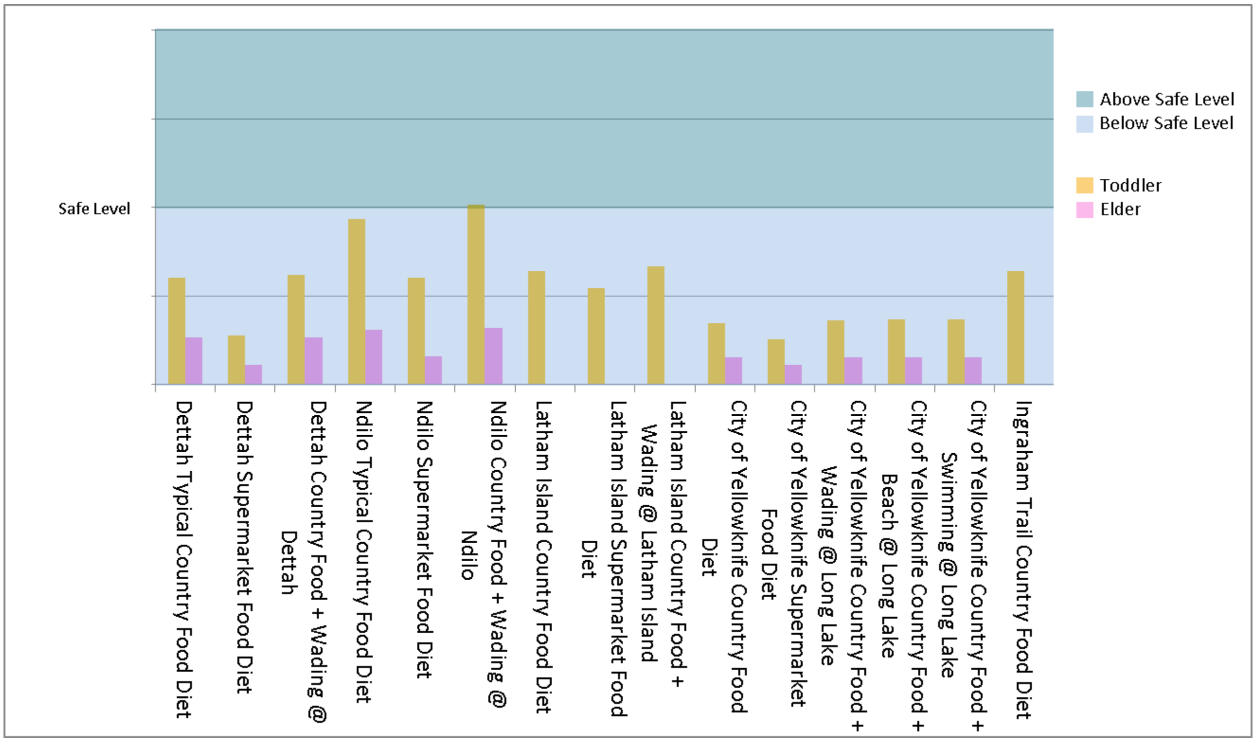
Figure 3.34 provides a summary of the estimated exposures to antimony calculated for the typical diet scenarios (i.e., typical country diet, Yellowknife country diet, and supermarket food diet). The results also include drinking municipal water, eating supermarket foods, exposure to soil and indoor dust (swallowing and skin contact), as well as breathing air. All of these exposures, with the exception of supermarket food, are unique to the location of the resident. Elders are not evaluated at Latham Island and Ingraham Trail. Additional scenarios that consider potential exposures from wading and swimming are also included in Figure 3.34. There is some double-counting for the antimony exposures presented in Figure 3.34 for receptors with country food diets, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods.

Figure 3.34 shows that all the results are at or below the safe level and, therefore, the risk from exposures to antimony in a typical country food diet is considered to be negligible. Antimony exposures are dominated by eating supermarket food and fish, which are considered to be background. The figure also demonstrates that toddlers are more exposed than elders. People who only eat supermarket food have the lowest exposures. While people who eat country foods have higher exposures than those who just eat supermarket foods, the figure shows that these exposures are still below the safe level.

From Figure 3.34, it can be seen that people who live in Ndilo and eat country foods are the highest exposed people. This is not surprising as they live closer to the Giant Mine and the antimony concentrations in soil are higher than at any other location; in addition they eat more country food than people living in the City. Wading in the near-shore sediments in any location increases exposures slightly.

For City of Yellowknife residents, including members of the Metis community, who eat country food, exposures are lower than for the YKDFN community living in Ndilo and Dettah, due to a smaller amount of country food being eaten as well as lower antimony in soil concentrations in the City of Yellowknife than in Ndilo and Dettah. The calculations also assumed that people from the City of Yellowknife would go to Long Lake and wade in the shallow sediments, play on the beach, and swim in the lake. The results show that either wading in the shallow sediments and swimming in Long Lake or spending time on the beach contributes only a slight increase in overall exposure to antimony and remains below the safe level.

Figure 3.34 Estimated potential exposures to antimony – typical diet scenarios

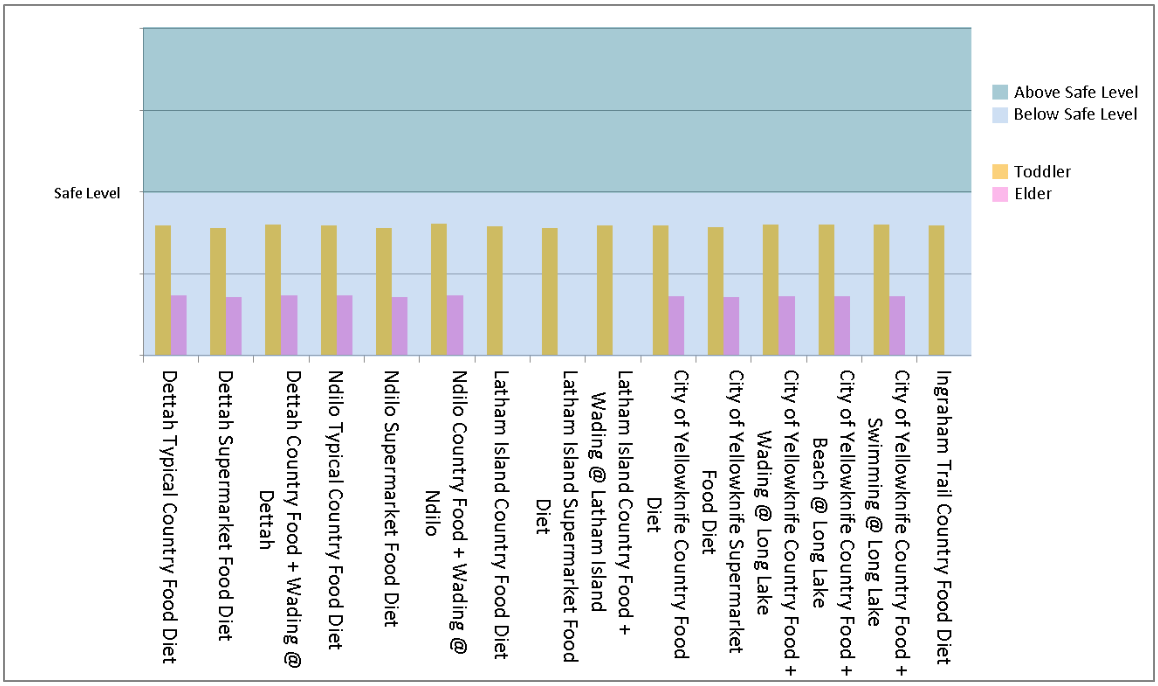


Manganese

Figure 3.35 provides a summary of the estimated exposures to manganese calculated for the typical diet scenarios (i.e., typical country diet, Yellowknife country diet, and supermarket food diet). The results also include drinking municipal water, eating supermarket foods, exposure to soil and indoor dust (swallowing and skin contact), as well as breathing air. All of these exposures, with the exception of supermarket food, are unique to the location of the resident. Elders are not evaluated at Latham Island and Ingraham Trail. There is some double-counting for the manganese exposures presented in Figure 3.35 for receptors with country food diets, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods.

Figure 3.35 shows that all the results are below the safe level and, therefore, the risk from exposures to manganese in a typical country food diet is considered to be negligible. As discussed in the exposure estimates in Section 3.3.8, the contribution of manganese in supermarket foods dominates the exposures and thus differences cannot be seen in the scenarios evaluated. Results for manganese are below safe levels for all other scenarios considered in the risk assessment and, thus, are considered to represent a negligible risk. The detailed results are presented in Appendix H; sample calculations are provided in Appendix I.

Figure 3.35 Estimated potential exposures to manganese – typical diet scenarios



High Diet Scenarios

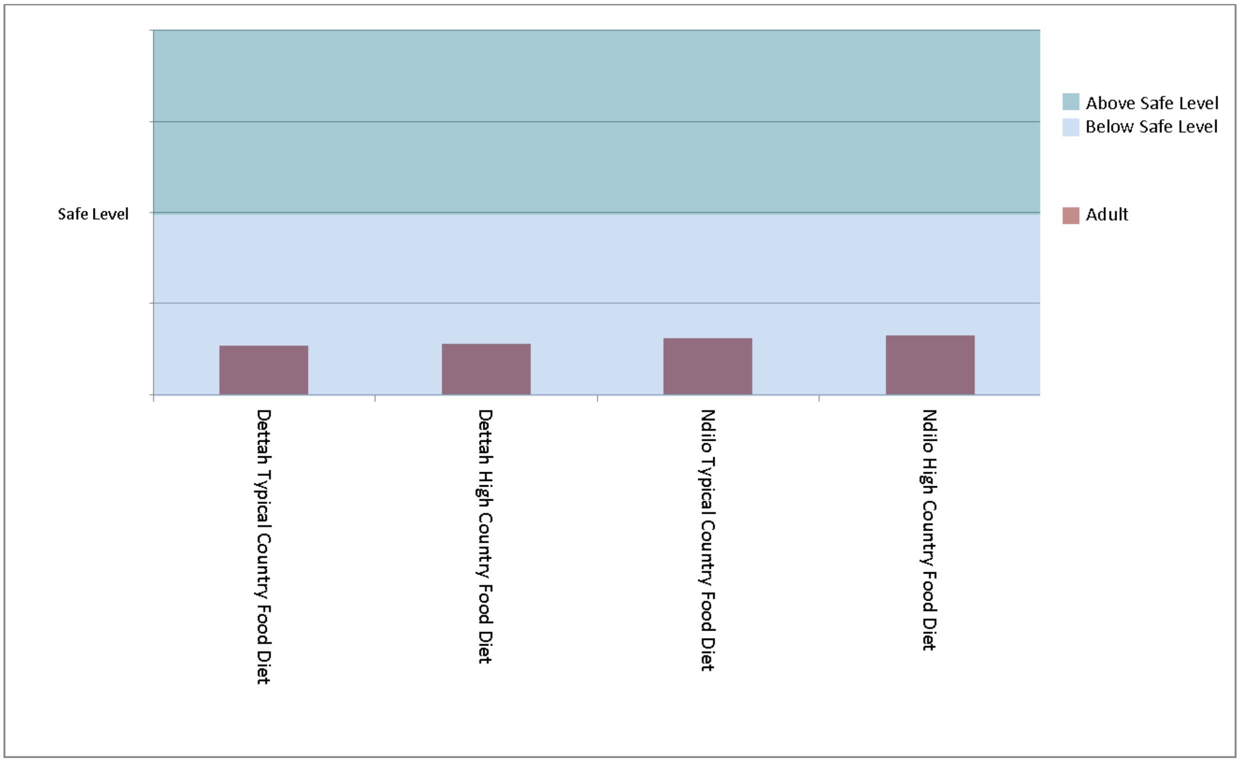
Antimony

The results of the dietary survey indicated that there were some adults in the 40 to 60 age group that ate a diet that was predominantly country foods. This section discusses the results for antimony exposures for people from the YKDFN who predominantly eat country foods.

Figure 3.36 provides a summary of the estimated exposures to antimony for the high country food diet and compares it to the typical country food diet in both Ndilo and Dettah. The results also include drinking municipal water, exposure to soil and indoor dust (swallowing and skin contact), as well as breathing air.

Figure 3.36 shows that high country food diet results in an increase in the antimony exposures; however, the exposures are below the safe level and, thus, are considered to represent negligible risk.

Figure 3.36 Estimated potential exposures to antimony – high diet scenarios



Additional Scenarios

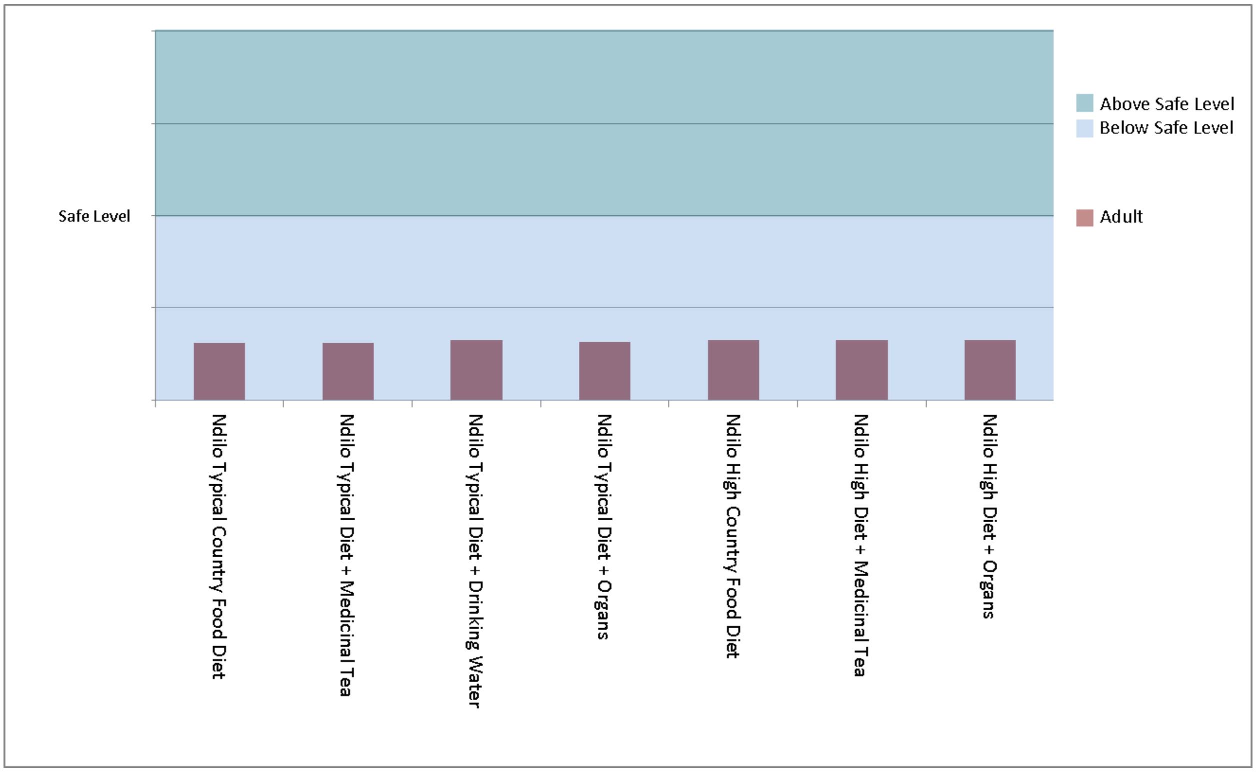
The additional scenarios only focus on antimony exposure, since manganese exposures are dominated by supermarket foods. The results for the antimony exposures are presented by location. People have reported drinking water from Yellowknife Bay, so this was considered as an additional scenario. Drinking medicinal tea and eating organs were considered as an additional scenario as not everyone reported eating them. The results are presented for adults only as they reported eating organs and drinking medicinal tea.

Ndilo

Figure 3.37 provides a summary of the estimated exposures to antimony calculated for the various scenarios considered for members of the Ndilo community. The results also consider the unique exposures in Ndilo. The drinking water scenario considers drinking water every day from North Yellowknife Bay. The ingestion of organs considered moose, fish, and bird organs. The figure shows the results for people with both a typical and a high country diet. There is some double-counting for the antimony exposures presented in Figure 3.37 for receptors with typical country food diets, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods.

Figure 3.37 shows that the results for all the additional scenarios for the Ndilo community are below the level of exposures considered safe for antimony and, thus, are considered to represent negligible risk. Exposures are typically higher for members of the Ndilo community who consume a high diet of country foods. The results show that drinking water from North Yellowknife Bay, drinking medicinal tea, or eating organs does not substantially add to antimony exposures.

Figure 3.37 Estimated potential exposures to antimony – additional scenarios for Ndilo

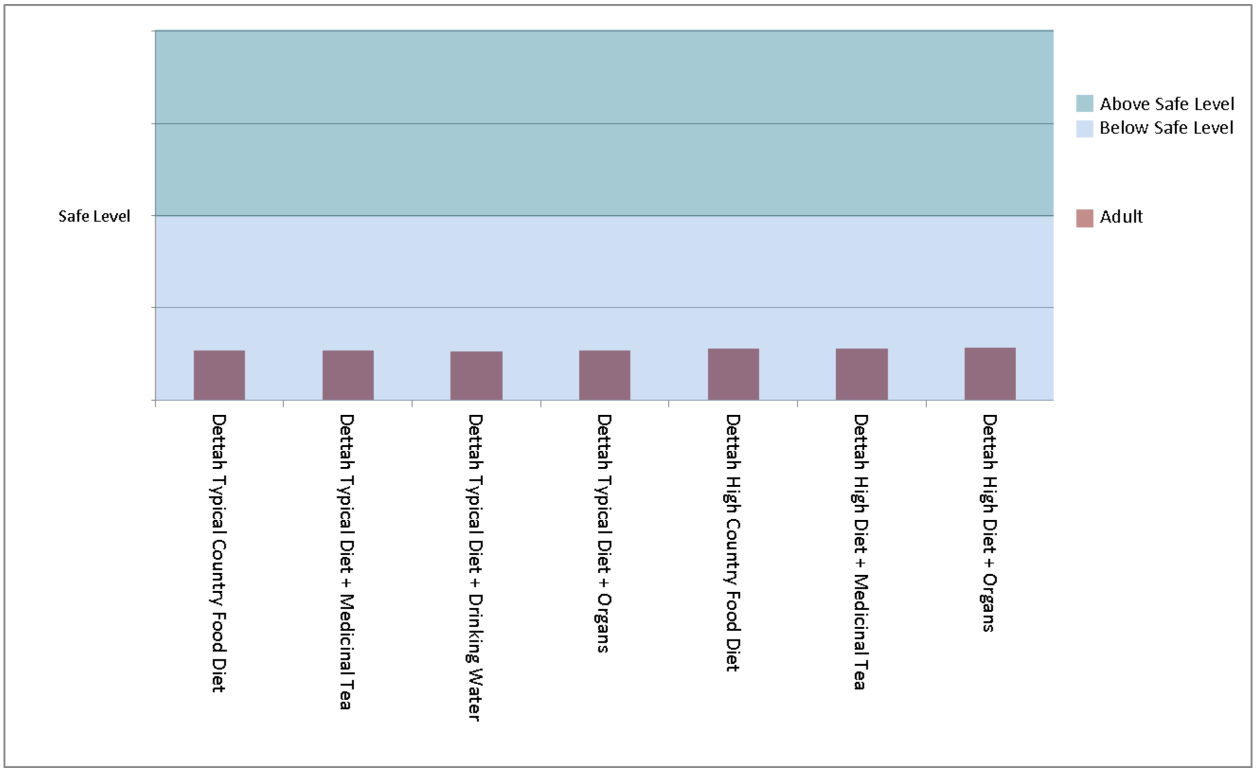


Dettah

Figure 3.38 provides a summary of the estimated exposures to antimony calculated for the various scenarios considered for members of the Dettah community. The results also consider the unique exposures in Dettah. The drinking water scenario considers drinking water every day from South Yellowknife Bay. The ingestion of organs considered moose, fish, and bird organs. The figure shows the results for people with both a typical and a high country diet. There is some double-counting for the antimony exposures presented in Figure 3.38 for receptors with typical country food diets, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods.

Figure 3.38 shows that the results for all the scenarios considered for the Dettah community are below the level of exposures considered safe for antimony and thus are considered to represent negligible risk. Exposures are typically higher for members of the Dettah community who consume a high diet of country foods. The results show that drinking water from South Yellowknife Bay, drinking medicinal tea, or eating organs does not substantially add to antimony exposures.

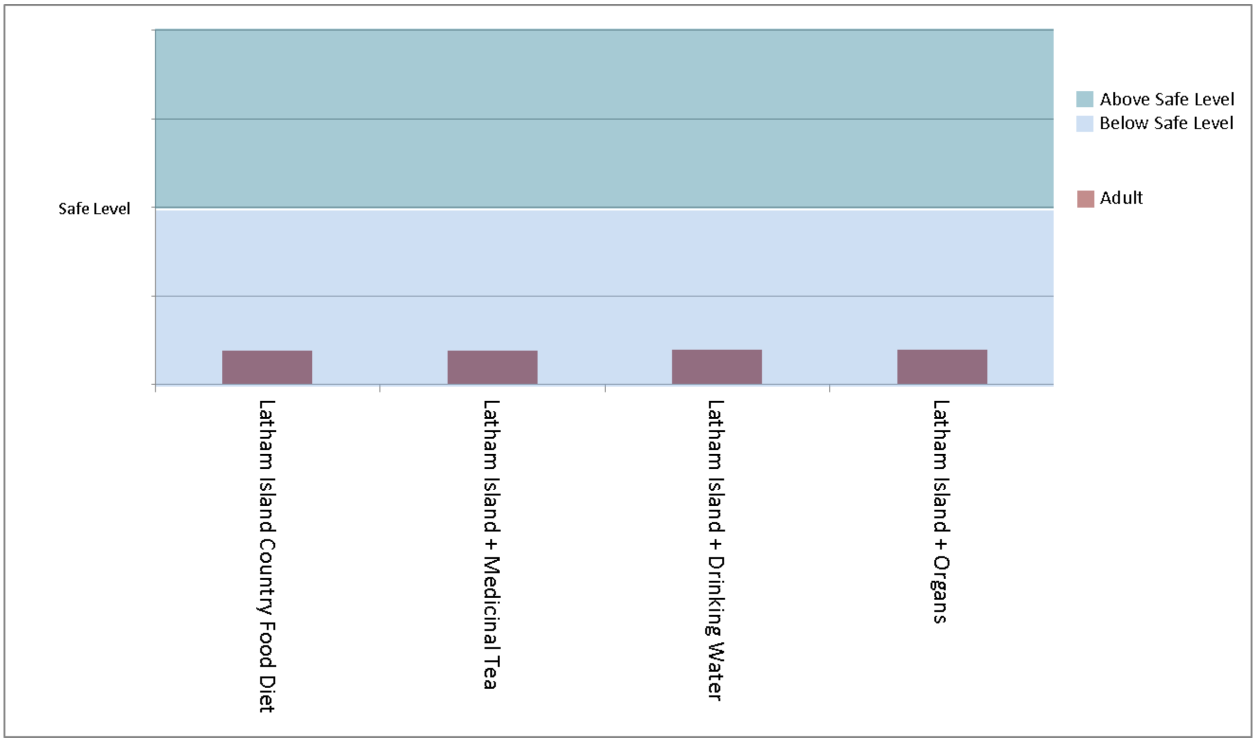
Figure 3.38 Estimated potential exposures to antimony – additional scenarios for Dettah



Latham Island

Figure 3.39 provides a summary of the estimated exposures to antimony calculated for the various scenarios considered for residents of Latham Island. The results also consider the unique exposures in Latham Island. The drinking water scenario considers drinking water every day from Back Bay and, therefore, covers the exposures from people living on houseboats who may get water from Back Bay. The ingestion of organs considered moose, fish, and bird organs. There is some double-counting for the antimony exposures presented in Figure 3.39, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods. Figure 3.39 shows that the results for all the scenarios considered for residents of Latham Island are all below the level of exposures considered safe for antimony and, thus, are considered to represent negligible risk. The results show that drinking water from Back Bay, drinking medicinal tea, or eating organs does not substantially add to antimony exposures.

Figure 3.39 Estimated potential exposures to antimony – additional scenarios for Latham Island

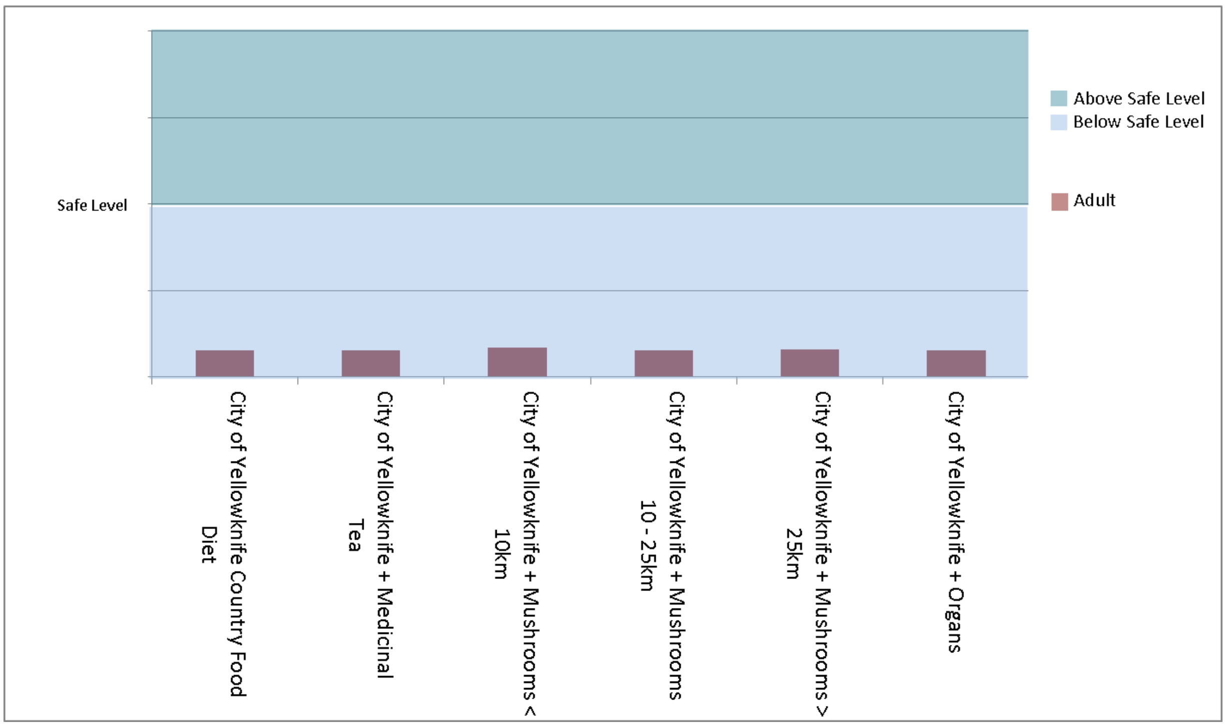


City of Yellowknife

Figure 3.40 provides a summary of the estimated exposures to antimony for the various scenarios considered for residents of the City of Yellowknife, including members of the Metis community. The results also consider the unique exposures in the City of Yellowknife. A drinking water scenario was not considered, as people living in the City of Yellowknife are serviced with municipal water. The Metis indicated in the dietary survey that they consumed mushrooms and, therefore, this scenario was also considered. The ingestion of organs considered moose, fish, and bird organs. There is some double-counting for the antimony exposures presented in Figure 3.40, since intakes from supermarket foods were not reduced to account for the foods obtained as country foods.

Figure 3.40 shows that the results for all the scenarios considered for residents of the City of Yellowknife, including members of the Metis community, are below the safe level of exposure for antimony and, thus, are considered to represent negligible risk. The results show that drinking medicinal tea, eating mushrooms, or eating organs does not substantially add to antimony exposures. The analysis of mushrooms considered consuming 1.5 kg of mushrooms a year for a lifetime, obtained from within 10 km of the Giant Mine, between 10 km and 25 km from the Giant Mine, and greater than 25 km from the Giant Mine. The figure shows that the antimony exposure from mushrooms does not vary much with distance from the Giant Mine. The results for the City of Yellowknife also reflect the results for people living along the Ingraham Trail as their country food diet is the same.

Figure 3.40 Estimated potential exposures to antimony – additional scenarios for City of Yellowknife



3.5.1.2 Estimation of Risk – Future Scenario

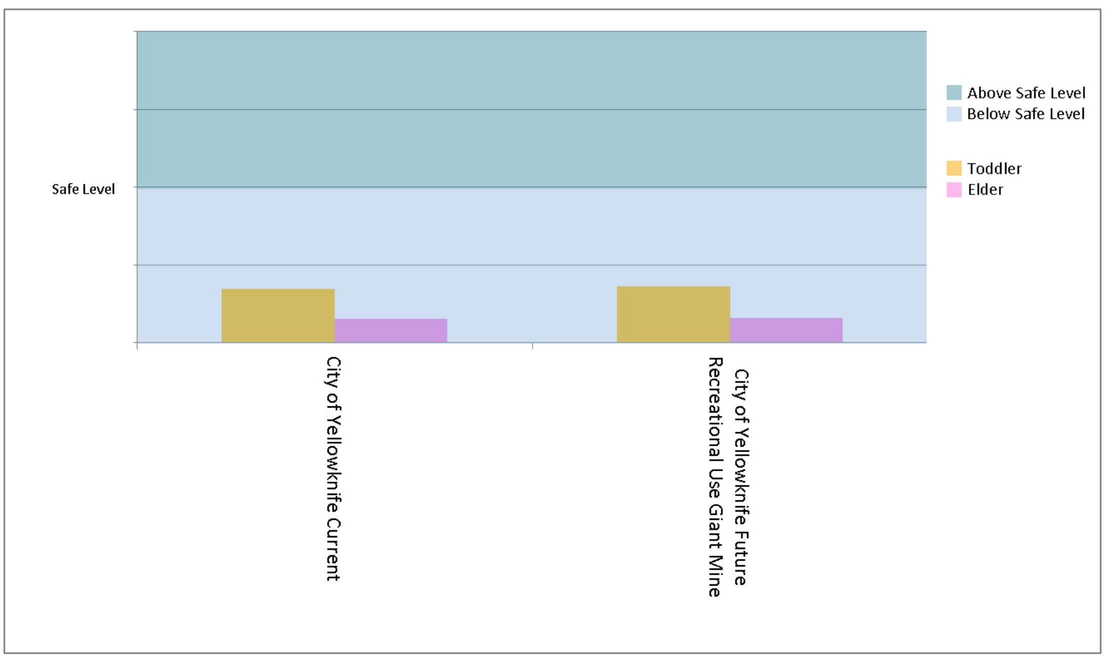
The future scenario examined the effect of post remediation conditions at the Giant Mine on the nearby residents. In the future, some parts of the Giant Mine may be accessible to members of the public for recreational activities, and people may collect berries when they are there. The relocation of the treatment plant outfall may potentially affect concentrations in Yellowknife Bay; however, predicted concentrations were determined to be similar to current conditions and thus were not evaluated for a future scenario. The future scenario considered residents in the City of Yellowknife as they have expressed the desire to use the Giant Mine in the future. The YKDFN have indicated that they do not want to use the site in the future so they were not considered in this scenario.

Antimony

Figure 3.41 provides a summary of the estimated exposures to antimony for future conditions for the City of Yellowknife. Results are provided for a toddler and elder. The results encompass multiple pathways of exposure, including drinking water from the municipal source, eating supermarket food, soil, indoor dust, and skin exposures, as well as exposures from air. The evaluation considered a typical country food diet. In order to provide a perspective, the results for the current base case exposure were also presented in the figure.

Figure 3.41 shows that future recreational use of the remediated Giant Mine, including picking berries and eating them while at the site, will contribute marginally to the total exposure of antimony for the City of Yellowknife residents. It is noted that the future scenario is below the safe level for antimony and, thus, is considered to represent negligible risk.

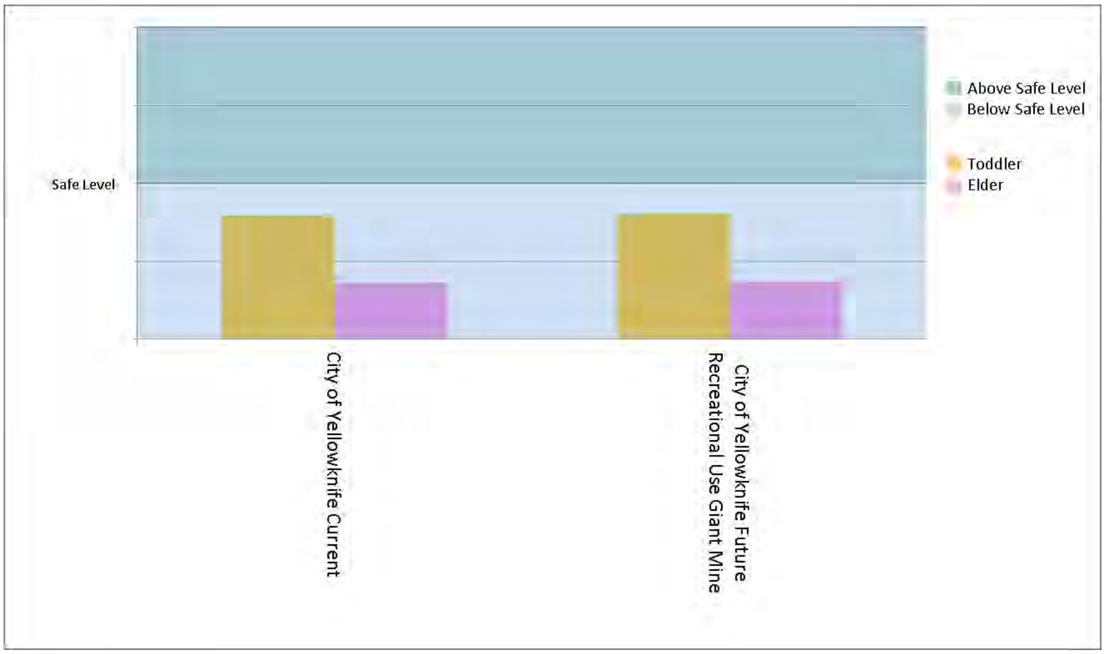
Figure 3.41 Estimated potential exposures to antimony – future conditions



Manganese

The similar scenario was evaluated for exposure to manganese. Figure 3.42 shows the results for the City of Yellowknife residents. Similar to the current scenario, supermarket food dominates the manganese exposure. The manganese exposure is below the safe level and, thus, considered to represent negligible risk.

Figure 3.42 Estimated potential exposures to manganese – future conditions



Former Giant Mine Townsite

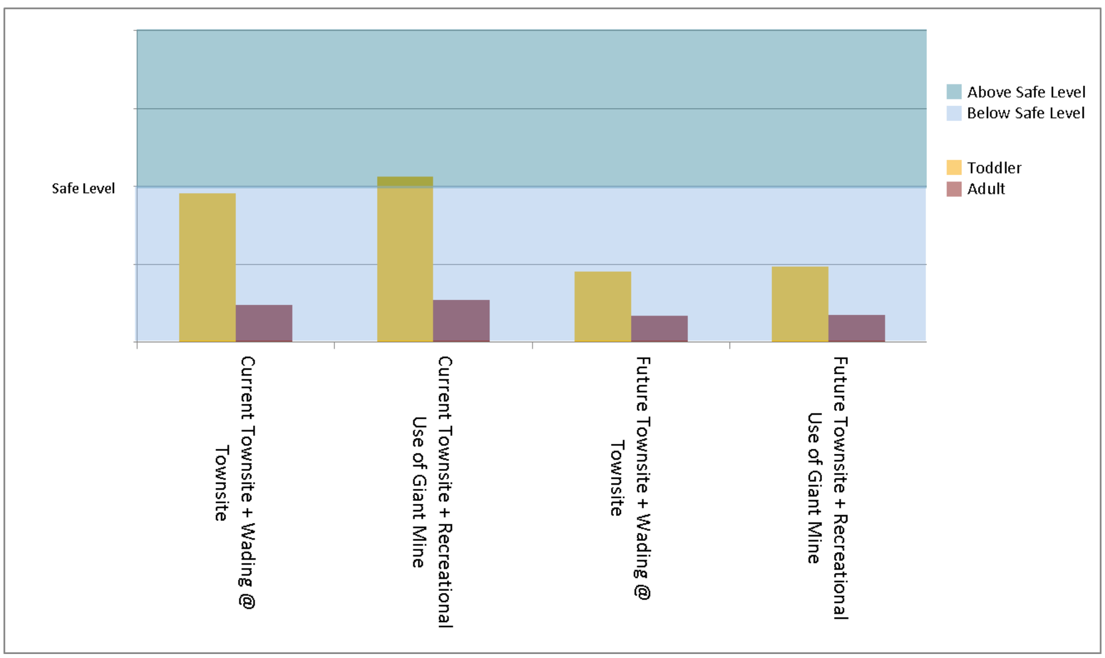
The GMRP has agreed to clean the arsenic in the soils at the marina and former Townsite as well as the shoreline that extends up to the Foreshore tailings to the GNWT residential criterion. When this occurs, antimony in the soils will also be cleaned up. It was assumed that the antimony in the soils will be about ten times lower than arsenic based on measured data. No definite plans have been made for the land use at the former Townsite. Therefore, the assessment considered that the most stringent land use (i.e., residential) would occur and it was assumed that people may live at this location.

Currently, there are no residents at the former Giant Mine Townsite; however, exposures from current levels of antimony at the Townsite were calculated in order to show the reduction in exposures from the soil clean up.

For the purposes of the assessment, it was assumed that the people living at the Townsite would have a country diet similar to the City of Yellowknife and would drink water provided by the municipality. People would also be exposed to soil and indoor dust and skin contact. It was also assumed that people in the Townsite would go on the Giant Mine for recreational activities and pick some berries. The sediments at the Townsite will also be remediated and a scenario was evaluated for wading in the shallow sediments. Figure 3.43 provides a summary of the estimated exposures to antimony for hypothetical residents at the Townsite location.

Figure 3.43 shows that under current conditions, the estimated exposures from antimony for hypothetical residents at the Townsite are below the safe level for antimony, with the exception of the totally unrealistic scenario of a toddler going on to the Giant Mine at current contamination levels. In the future, following planned remediation activities to soils and sediments at the Townsite, the results show that exposure levels in the future will be much lower than for current conditions. This comparison shows that the remediation activities planned for the Townsite and Giant Mine are expected to result in lower exposures and, thus, a positive outcome in this location. This also covers risks and exposures at the marina.

Figure 3.43 Estimated potential exposures to antimony – former Townsite



3.5.1.3 Interpretation of Risk Estimates

The results of the risk assessment for current scenarios for exposure to antimony and manganese indicate that the risks are considered to be negligible.

For the future, after the Giant Mine has been remediated, the risks are also considered to be negligible.

At the former Townsite location and marina, the remedial activities will reduce antimony concentrations and, under a residential scenario (most restrictive land use), the risks are considered to be negligible.

3.5.2 Cancer-Causing COPC

Of the COPC identified for the HHRA, arsenic is known to cause cancer. The evaluation of potential risks from exposure to arsenic is completed on an incremental basis (i.e. Incremental risk = Total risk – Background risk). In many cases, it is difficult to separate incremental risk from total risk. Total cancer risk is calculated by adding all exposures to a particular chemical, including background exposures.

Any level of exposure to a cancer-causing chemical such as arsenic is associated with some level of risk. Thus, an acceptable level of risk must be set for these chemicals. Acceptable risks are provided by regulators in the form of incremental lifetime cancer risks, which are set at risk levels considered to be negligible. Health Canada's negligible incremental lifetime cancer risk level is one-in-one hundred thousand people (1 in 100,000).

For cancer-causing chemicals, risk is calculated by multiplying the average daily dose over a lifetime, which includes all life stages combined (lifetime receptor) by the cancer slope factor (TRV) to estimate the incremental lifetime cancer risk.

In order to provide a context for the incremental risks associated with arsenic exposure in this study, a framework, which has been used by recognized experts in the field of risk communication (Calman 1996; Paling 2003), was adopted. The different levels of risk are described below (Calman 1996):

- High: These risks may be fairly regular events and would occur at a rate greater than 1 in 100. They may also be described as frequent, serious, or significant.

- Moderate: This term relates to a risk of between 1 in 1,000 and 1 in 100. This would apply to a wide range of medical procedures (e.g., whole CT scans nuclear stress tests) and environmental events.
- Low: This relates to a predicted increased risk of between 1 in 10,000 and 1 in 1,000. Again, many risks of clinical procedures (e.g., barium enemas, partial CT scans) and environmental hazards fit into this broad category. Other words that might be used include reasonable, tolerable, and small.
- Very Low: This describes a risk between 1 in 100,000 and 1 in 10,000; many health care interventions (e.g., dental x-rays, chest x-rays, mammograms) have adverse effects that are in this range.
- Negligible: Health Canada describes this as an adverse event occurring in less than 1 per 100,000 people. While still important to identify and monitor, such a risk would be of little concern for normal living. Another word that could be used to describe this risk level is insignificant. Health Canada considers that remedial activities should be implemented to reduce risks to a negligible risk level.

3.5.2.1 Estimation of Risk (Incremental Lifetime Cancer Risks) – Current Scenario

Potential risks are evaluated on a lifetime basis, which is done through the use of a lifetime receptor. As described in Section 3.3.2.10, various durations of exposure for each life stage were considered in order to estimate a lifetime risk to a receptor. A lifetime receptor was calculated assuming 4 years as a toddler, 6 years as a child, 8 years as a teen, 52 years as an adult, and 10 years as an elder, for a total of 80 years of exposure. The results presented below for arsenic are estimated incremental lifetime cancer risks for a lifetime receptor.

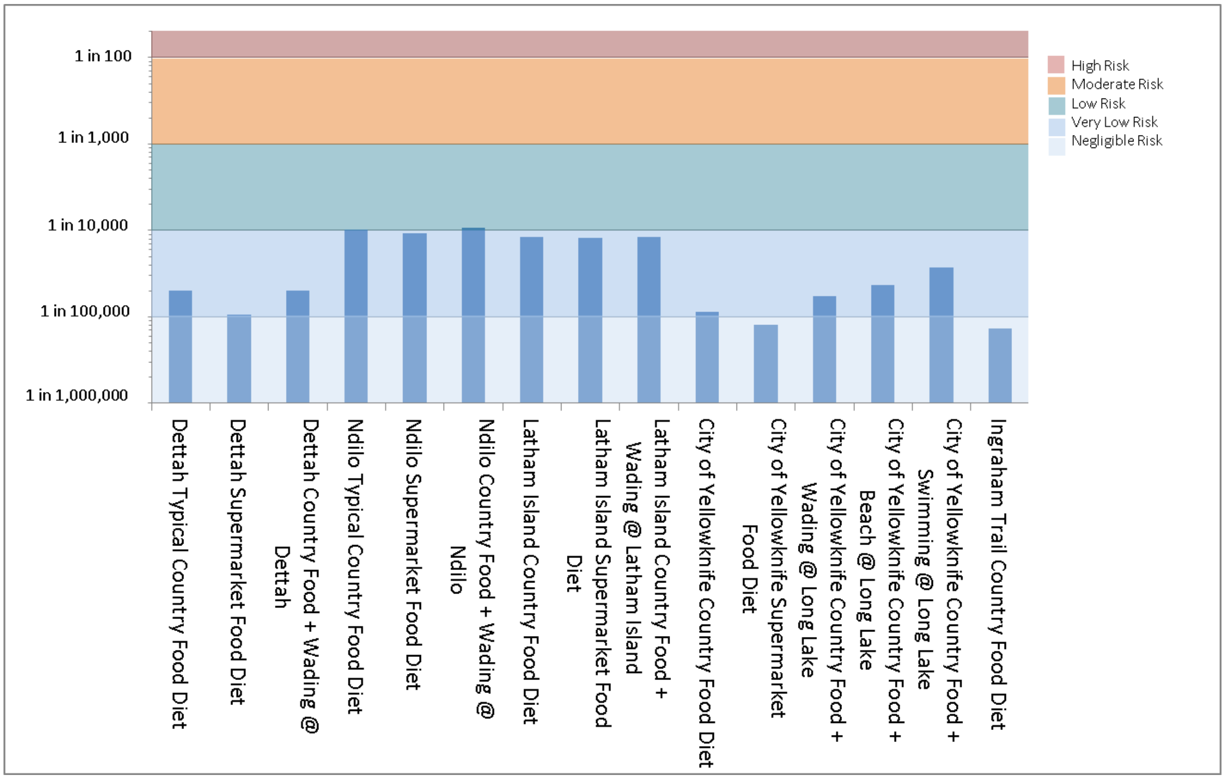
To determine the incremental risks, the background exposure was subtracted from the total exposures to determine the incremental exposure, and then the risk was calculated. For drinking water, the background exposure was based on drinking the municipal water supply, as that source is not deemed to be affected by the Giant Mine. For soils, the background concentrations for all locations, with the exception of Dettah, are based on background derived from samples obtained from within the Greenstone Belt, as these locations are in this same mineralized area. For Dettah, the background was based on regional soil samples. Sediment background was obtained from Horseshoe Island in Yellowknife Bay and the background diet concentrations have been discussed in Section 3.3.6. Appendix C provides the description and values for the background concentrations. The EPCs and background concentrations used in the calculations are provided in Appendix F. Detailed results, including a breakdown by exposure pathway, are provided in Appendix H; sample calculations are provided in Appendix I.

Typical Diet Scenarios

Figure 3.44 provides a summary of the estimated incremental lifetime cancer risks from arsenic calculated for the typical diet scenarios (i.e., typical country diet, Yellowknife resident diet, and supermarket food diet). The results encompass multiple pathways of exposure, including municipal drinking water, country and supermarket foods, soil, indoor dust, and skin exposures as well as exposures to arsenic in air. Background exposures associated with these pathways are not included. Additional scenarios that consider potential exposures from wading and swimming are also included.

Figure 3.44 shows that the results for all locations are within the very low risk or negligible risk category. It should be noted that these very low risks are similar to going to the dentist and having x-rays or having a chest x-ray. As discussed in Section 3.3.8, the incremental arsenic exposures are dominated by soil and indoor dust exposures at the residential locations. People who only eat supermarket foods in the City of Yellowknife have the lowest estimated incremental risk levels, and these levels are considered to be negligible risks. People who eat country foods and live on the Ingraham Trail also have negligible risks. Generally, country food eaters have higher incremental risks, although they are within the range of very low risk levels.

Figure 3.44 Estimated incremental lifetime cancer risk from arsenic – typical diet scenarios



Calculated incremental arsenic risk levels for people living in Ndilo are above the negligible risk level and are generally higher than the other locations but within the very low risk range. The exposures are higher due to exposure to arsenic in soil and indoor dust associated with historical contamination in the soils in Ndilo when the Giant Mine was in operation. Figure 3.44 shows that there is very little difference in estimated risk levels between people who eat a typical diet of country foods and people who eat supermarket foods; additionally, wading in near-shore sediments at Ndilo does not contribute significant additional risk from arsenic exposure. Residents of Latham Island have similar, though slightly lower, estimated incremental arsenic risk levels as Ndilo community members. This is not surprising as soil data from Ndilo was used for Latham Island.

From Figure 3.44, it can be seen that community members of Dettah who eat a typical diet of country foods have a very low incremental lifetime cancer risk from arsenic; additional consideration of wading in the near-shore sediments at Dettah does not add significantly to the arsenic risk since arsenic in the sediments are near background levels.

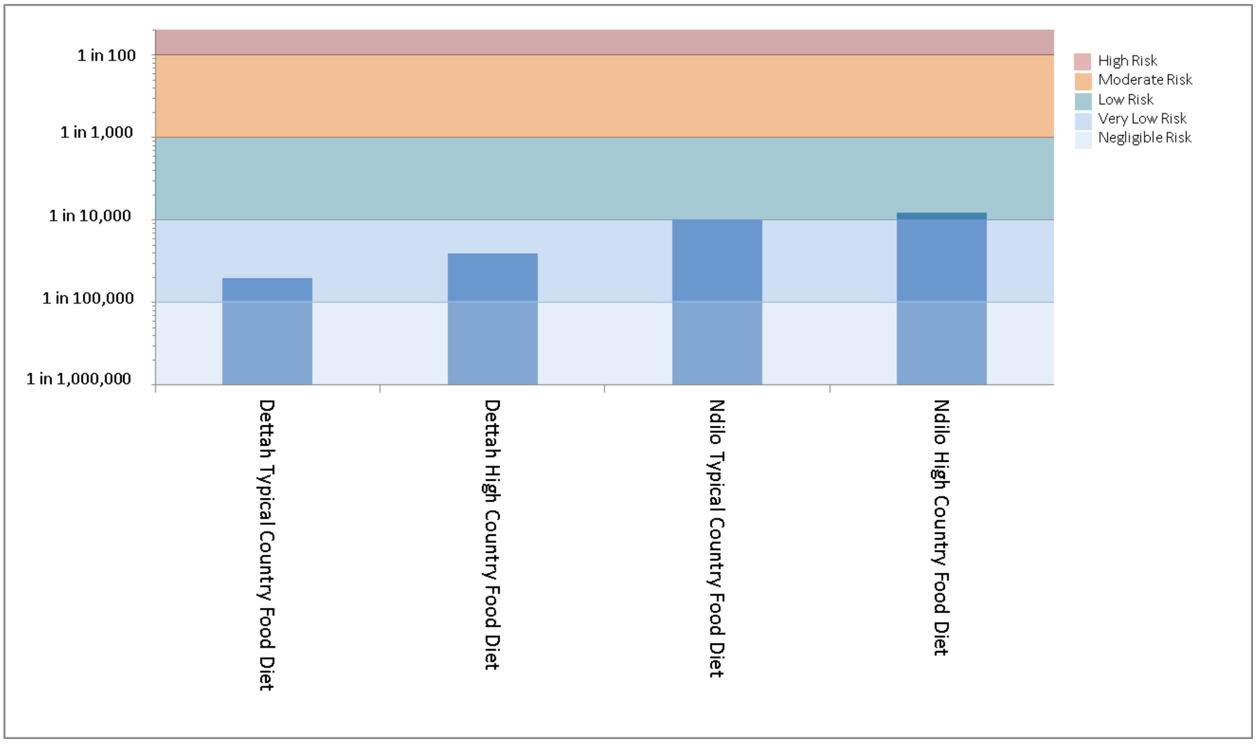
The very low risks for City of Yellowknife residents, including members of the Metis community, with a country food diet increase slightly for exposures to sediment at Long Lake, either through wading or spending time on the beach. Swimming at Long Lake also contributes to exposures, although estimated risks remain in the very low risk level.

High Diet Scenarios

Figure 3.45 provides a summary of the estimated incremental lifetime cancer risks from arsenic calculated for the high country food diet and compares it to the typical country food diet in both Ndilo and Dettah. The results also include drinking municipal water, exposure to soil and indoor dust (swallowing and skin contact), as well as breathing air.

As seen in Figure 3.45, the high diet scenario results in a higher arsenic exposure than for the typical diet. For Dettah residents, the risks are in the very low category. For Ndilo residents, the risks just tip over into the low category. Risks in the low category are similar to having a CT scan. It should be noted here that it is assumed that the high eater eats a high diet of country food for his/her lifetime. Again, it must be emphasized that the incremental risks are dominated by soil and indoor dust exposure at the residential locations.

Figure 3.45 Estimated incremental lifetime cancer risk from arsenic – high diet scenarios



Additional Scenarios

People have reported drinking water from Yellowknife Bay, so this was considered as an additional scenario. Drinking medicinal tea and eating organs were not considered in the typical diets above as not everyone reported eating them. Thus, the additional scenarios considered these exposures.

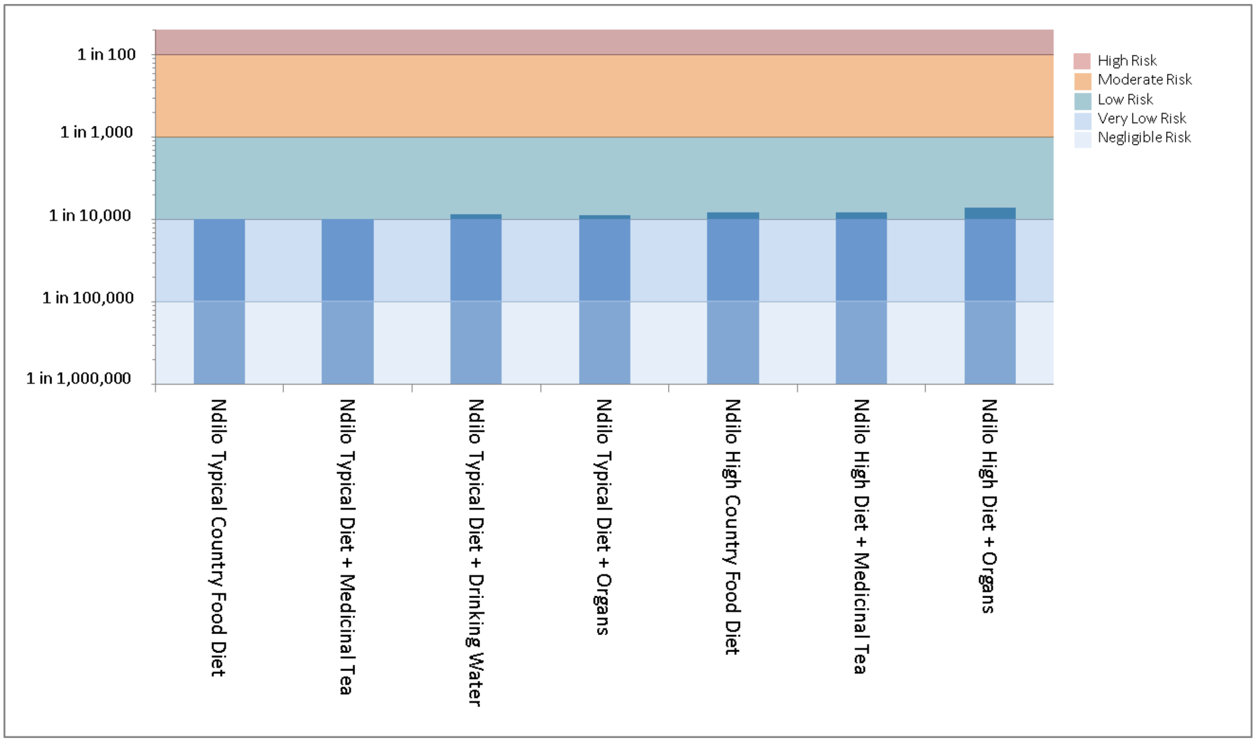
Ndilo

Figure 3.46 provides a summary of the estimated exposures to arsenic for the various scenarios considered for members of the Ndilo community. The results also consider the unique exposures in Ndilo. The drinking water scenario considers drinking water every day from North Yellowknife Bay. The ingestion of organs included eating moose, fish, and bird organs. The figure shows the results for people with both a typical and a high country diet.

Figure 3.46 shows that the results for all the scenarios considered for the Ndilo Community are within the very low risk category with the exception of drinking water every day from North Yellowknife Bay and eating fish where the risks just tip into the low risk category. These risks are similar to having an x-ray or a CT scan. Exposures are typically higher for people with a high diet of country foods, although results do not differ a lot between the scenarios. This is due to the fact that incremental risk levels calculated for arsenic are dominated by exposures to soil and indoor dust at this location which are as a result of historic contamination from activities at the Giant Mine when it was in operation. Therefore, changes to diet assumptions have little effect on the overall risk level.

Drinking water from North Yellowknife Bay every day increases the arsenic risks slightly; however, consumption of medicinal tea and animal organs from moose, fish, and grouse do not contribute significantly to the estimated incremental lifetime cancer risk from arsenic. It is noted that rat root samples were similar to rat root samples from background locations and do not result in any incremental risk.

Figure 3.46 Estimated incremental lifetime cancer risk from arsenic – additional scenarios for Ndilo



Dettah

Figure 3.47 provides a summary of the estimated exposures to arsenic for the various scenarios considered for members of the Dettah community. The results also consider the unique exposures in Dettah. The drinking water scenario considers drinking water every day from South Yellowknife Bay. The ingestion of organs included eating moose, fish, and bird organs. The figure shows the results for people with both a typical and a high country diet.

Figure 3.47 Estimated incremental lifetime cancer risk from arsenic – additional scenarios for Dettah

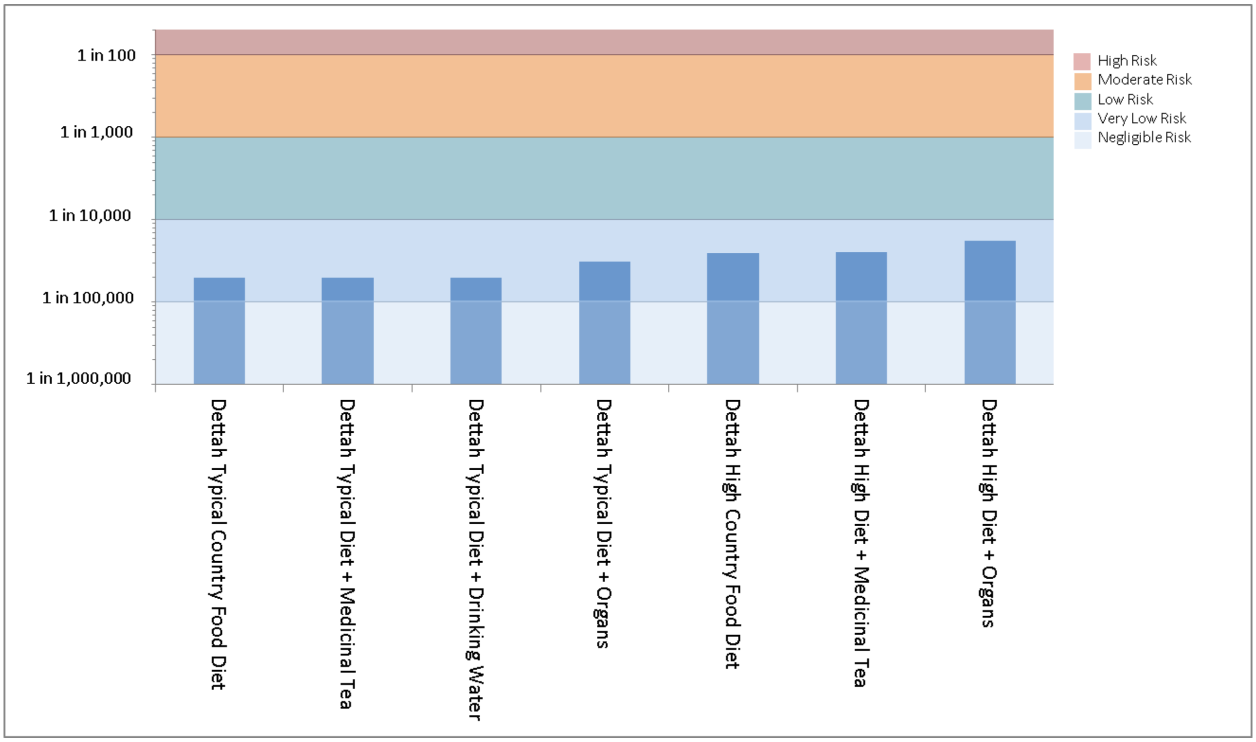


Figure 3.47 shows that the results for all the scenarios considered for the Dettah Community are within the very low risk category. This is similar to going to the dentist and having x-rays or having a chest x-ray. Exposures are typically higher for members of the Dettah Community who consume a high diet of country foods.

For Dettah Community members, additional consideration of drinking medicinal tea, drinking water from South Yellowknife Bay (as opposed to from the municipal water supply), and eating animal and fish organs do not contribute significantly to the estimated incremental lifetime cancer risk from arsenic. It is noted that rat root samples were similar to rat root samples from background locations and do not result in any incremental risk.

Latham Island

Figure 3.48 provides a summary of the estimated exposures to arsenic for the various scenarios considered for residents of Latham Island. The results also consider the unique exposures in Latham Island. The drinking water scenario considers drinking water every day from Back Bay and, therefore, covers the exposures from people living on houseboats who may get water from Back Bay. The ingestion of organs included eating moose, fish, and bird organs.

Figure 3.48 Estimated incremental lifetime cancer risk from arsenic – additional scenarios for Latham Island

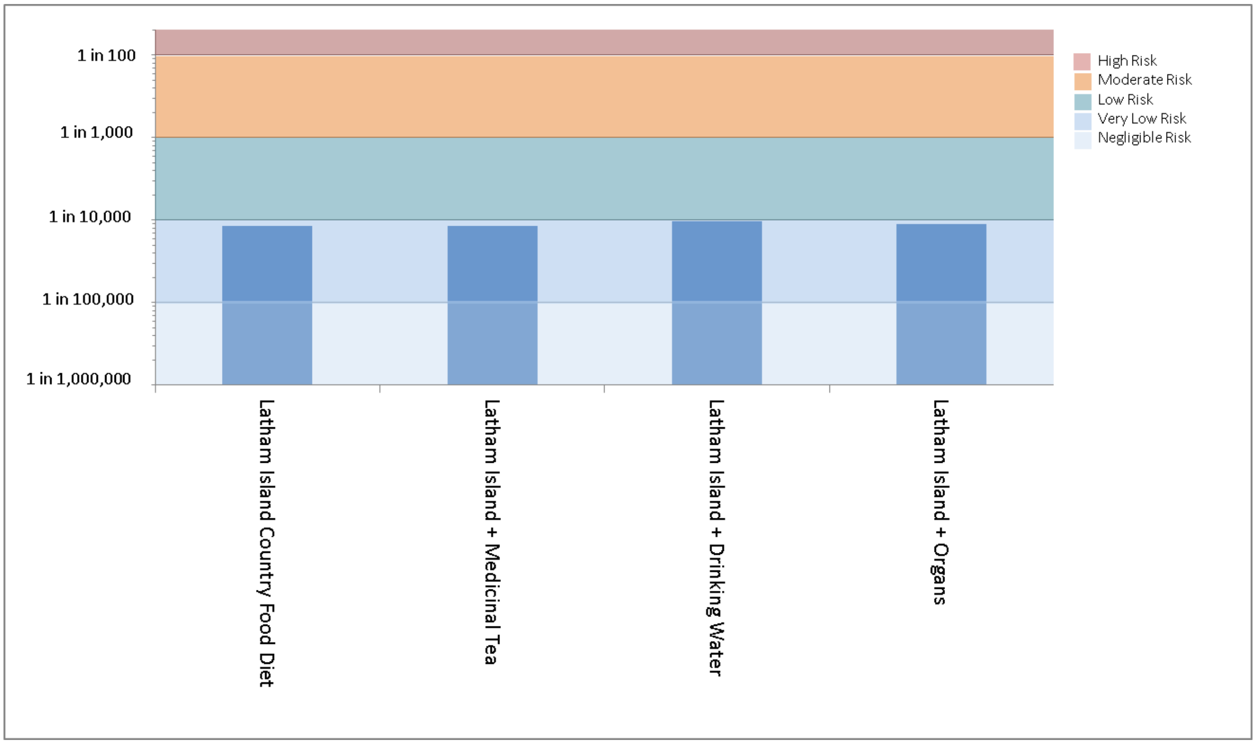

Figure 3.48 shows that the results for all the scenarios considered for residents of Latham Island are within the very low risk category and are similar to having x-rays. It should be noted that soil and dust are the main exposure pathways and it was assumed that the arsenic concentration in soils on Latham Island are similar the arsenic concentration in soils from Ndilo. For residents of Latham Island with a diet of country foods, additional consideration of drinking medicinal tea and eating animal and fish organs do not contribute significantly to the estimated incremental lifetime cancer risk from arsenic. Drinking water from Back Bay (as opposed to from the municipal water supply) every day adds to the arsenic exposure; however, estimated risk levels are still within the very low risk category.

City of Yellowknife

Figure 3.49 provides a summary of the estimated exposures to arsenic for the various scenarios considered for residents of the City of Yellowknife, including members of the

Metis community. The results also consider the unique exposures in the City of Yellowknife. A drinking water scenario was not considered as people living in the City of Yellowknife are serviced with municipal water. The Metis indicated in the dietary survey that they consumed mushrooms and, therefore, this scenario was also considered. The ingestion of organs included eating moose, fish, and bird organs.

Figure 3.49 Estimated incremental lifetime cancer risk from arsenic – additional scenarios for City of Yellowknife

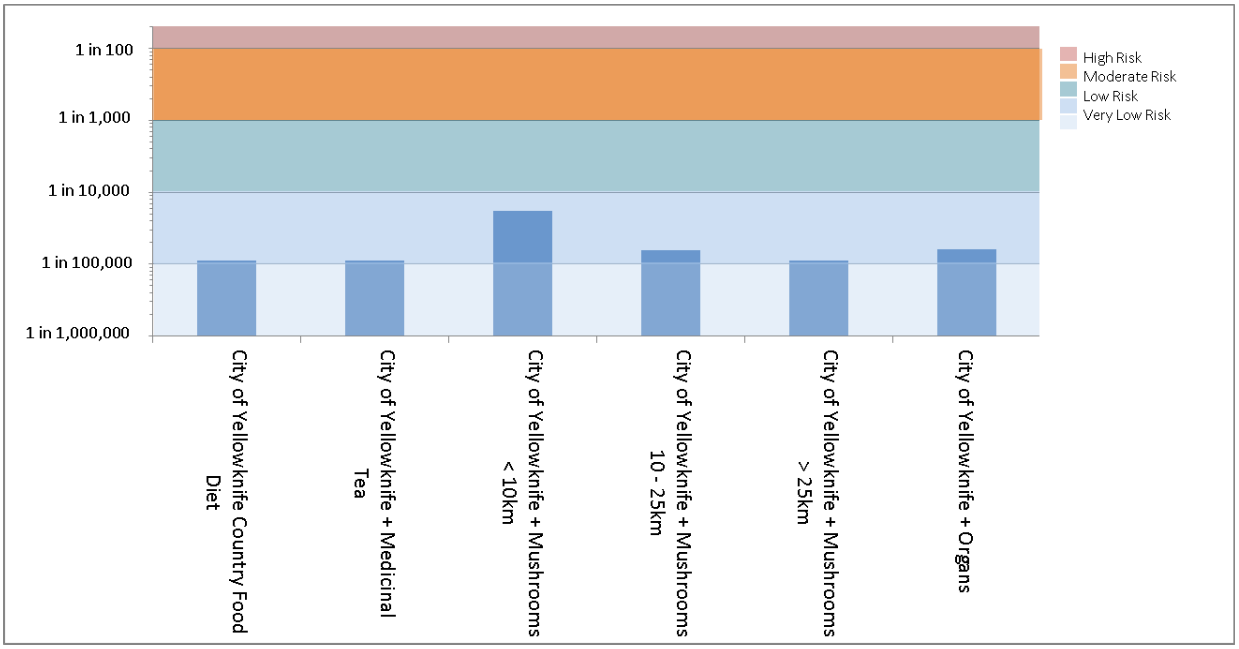

Figure 3.49 shows that the results for all the scenarios, with the exception of eating mushrooms gathered from within 10 km of the Giant Mine, considered for residents of the City of Yellowknife, including members of the Metis community, are considered to be in the low end of the very low risk category. Drinking medicinal tea and eating animal and fish organs do not contribute significantly to the estimated incremental lifetime cancer risk from arsenic. The exposure for the Ingraham Trail resident is captured in this scenario as their diet of country food is the same as for the City of Yellowknife.

Mushrooms were collected from different areas around Yellowknife in the summer and fall of 2017 and the results are presented in Appendix P. The data were summarized into different distances from the Giant Mine. It was assumed that people would consume about 1.5 kg of mushrooms a year for 60 years from the different areas. The results show that eating 1.5 kg of mushrooms a year from areas greater than 25 km from the Giant Mine does not change the incremental risk from arsenic exposure. Eating about 1.5 kg of mushrooms per year from a distance of 10 km to 25 km increases the risk slightly; however the risks are still in the very low risk category. Eating 1.5 kg of mushrooms a year from within 10 km of the Giant Mine (Golf Course, Vee Lake Area and south east part of the City) increases the risk to the upper end of the very low category. As seen in Appendix P, in order to represent a negligible risk, someone should only eat about 300 g per year of mushrooms from within 10 km of the Giant Mine. Mushrooms from the Rat Lake area have about three times the arsenic concentrations as those from the other areas within the 10 km area and the GNWT Health Department has an advisory indicating that mushrooms should not be collected from Rat Lake. It should be noted that this analysis did not included the species *Tricholomatacea* which concentrates arsenic to very high concentrations. Results for eating *Tricholomatacea* are presented in Appendix P.

3.5.2.2 Estimation of Risk (Incremental Lifetime Cancer Risks) – Future Scenario

The future scenario examined the effect of post remediation conditions at the Giant Mine on the nearby residents. In the future, some parts of the Giant Mine may be accessible to members of the public for recreational activities, and people may walk on the site and collect berries. Some stakeholders have indicated that they would like to use the Giant Mine in the future and this scenario captures that exposure. It is noted that members of the YKDFN do not want to use the Giant Mine in the future. A City of Yellowknife resident was evaluated as they indicated that they may want to use the Giant Mine in the future.

Figure 3.50 provides a summary of the estimated incremental lifetime cancer risks from arsenic calculated for future conditions. The results encompass multiple pathways of exposure, including drinking water, country foods, soil, indoor dust from the residential area, and dermal exposures as well as exposures to arsenic in air.

Figure 3.50 Estimated incremental lifetime cancer risk from arsenic – additional scenarios for future conditions

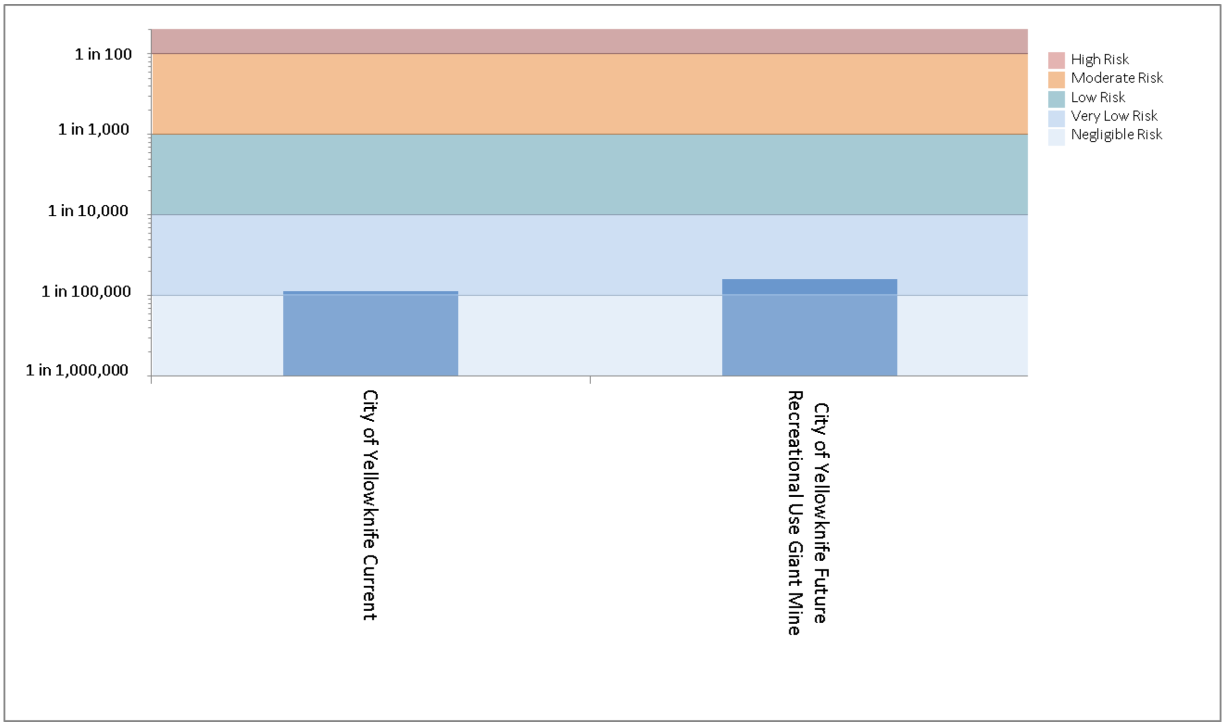

Figure 3.50 shows that for the City of Yellowknife residents using the Giant Mine recreationally in the future, including eating berries, the estimated incremental lifetime cancer risk is slightly above the levels predicted currently but is at the low end of the very low risk category.

Hypothetical Townsite Scenarios

As discussed previously, the GMRP has agreed to clean the arsenic in the soils at the marina and former Townsite as well as the Shorelands up to the Foreshore tailings to the GNWT residential criterion of 160 mg/kg. No definite plans have been made for the land use at the former Townsite or marina; however, the assessment considered that the most stringent land use (i.e., residential) would occur and people would live at this location.

Currently, nobody lives at the former Giant Mine Townsite; however, exposures from current levels of arsenic at the Townsite were calculated in order to illustrate the reduction in exposures from remediation activities planned for the Townsite.

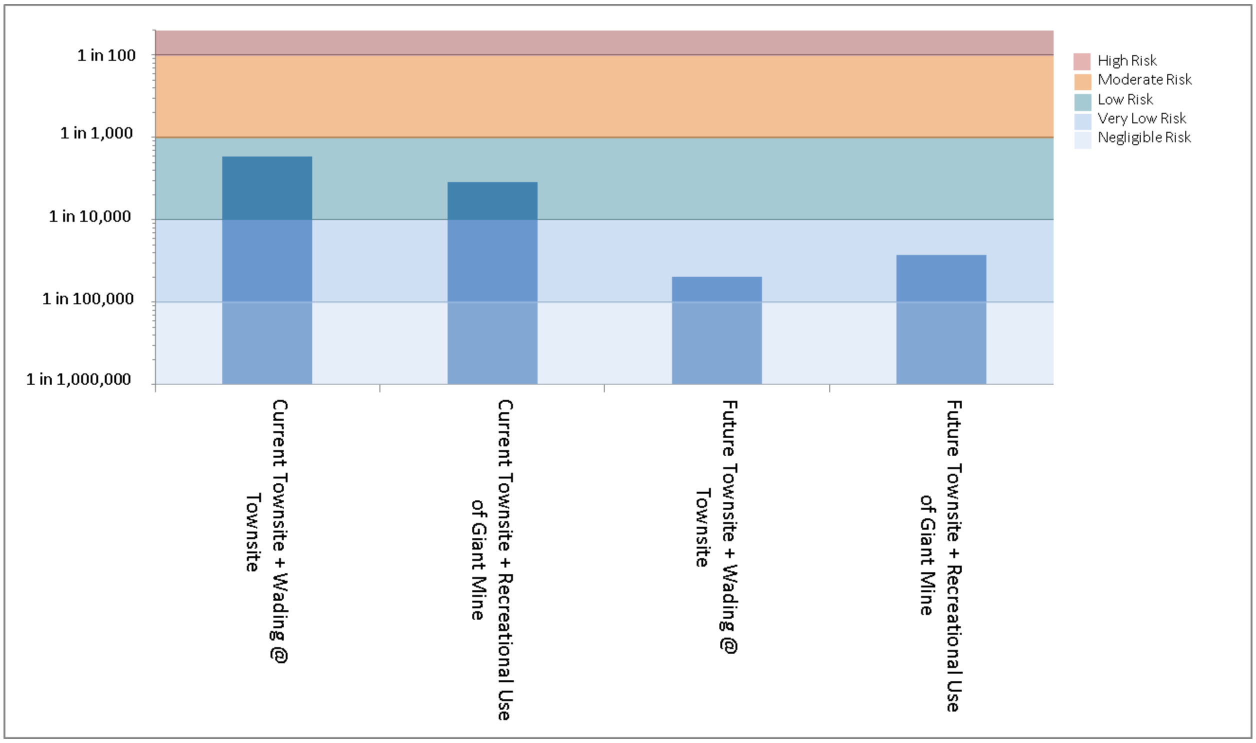
For the purposes of the assessment, it was assumed that the people living at the Townsite would have a country diet similar to the City of Yellowknife and would drink water that was provided by the municipality. People would also be exposed to soil and indoor dust through ingestion as well as skin contact. It was also assumed that people in the Townsite would go on the Giant Mine for recreational activities and pick some berries. The sediments at the Townsite will also be remediated, and a scenario was evaluated for wading in the shallow sediments.

Figure 3.51 provides a summary of the estimated incremental lifetime cancer risks from arsenic calculated for the hypothetical residents at the former Giant Mine Townsite location.

Figure 3.51 shows that in the future, following planned remediation activities to soils and sediments at the Townsite, the estimated lifetime cancer risk levels are within the very low risk category. Since the remediation plan for the Townsite has not been determined, it was assumed that people may live there, as this is the most restrictive potential use of the Townsite. The recreational use exposure scenario considers recreational use of the Giant Mine, including the collection of berries while at the Giant Mine. The results show that while the arsenic exposure increases for this scenario, the risks remain in the very low risk category. These risks are similar to having dental x-rays or a chest x-ray.

A comparison of current and future results in Figure 3.51 shows the remediation activities planned for the Townsite and Giant Mine are expected to reduce the exposure to arsenic at these locations by about 30 times. The results are also similar for the marina location.

Figure 3.51 Estimated incremental lifetime cancer risk from arsenic – additional scenarios for hypothetical Townsite



3.5.2.3 Interpretation of Risk Estimates

The results of the risk assessment for current scenarios of arsenic exposure indicate that the risks are determined to be in the negligible to very low range, with a few scenarios, generally associated with Ndilo being within the low end of the low risk region. The incremental arsenic risks are dominated by soil and indoor dust exposure from soils present at Ndilo, Dettah, Latham Island, City of Yellowknife, and Ingraham Trail locations. For the future, after the Giant Mine has been remediated, the risks will not be changed substantially, as the remediation activities at the Giant Mine will have no influence on the arsenic in soil concentrations measured at the various locations. Elevated arsenic concentrations in soils in Ndilo are a result of historical contamination from when the Giant Mine was in operation. It has been assumed that these elevated concentrations are similar in Latham Island.

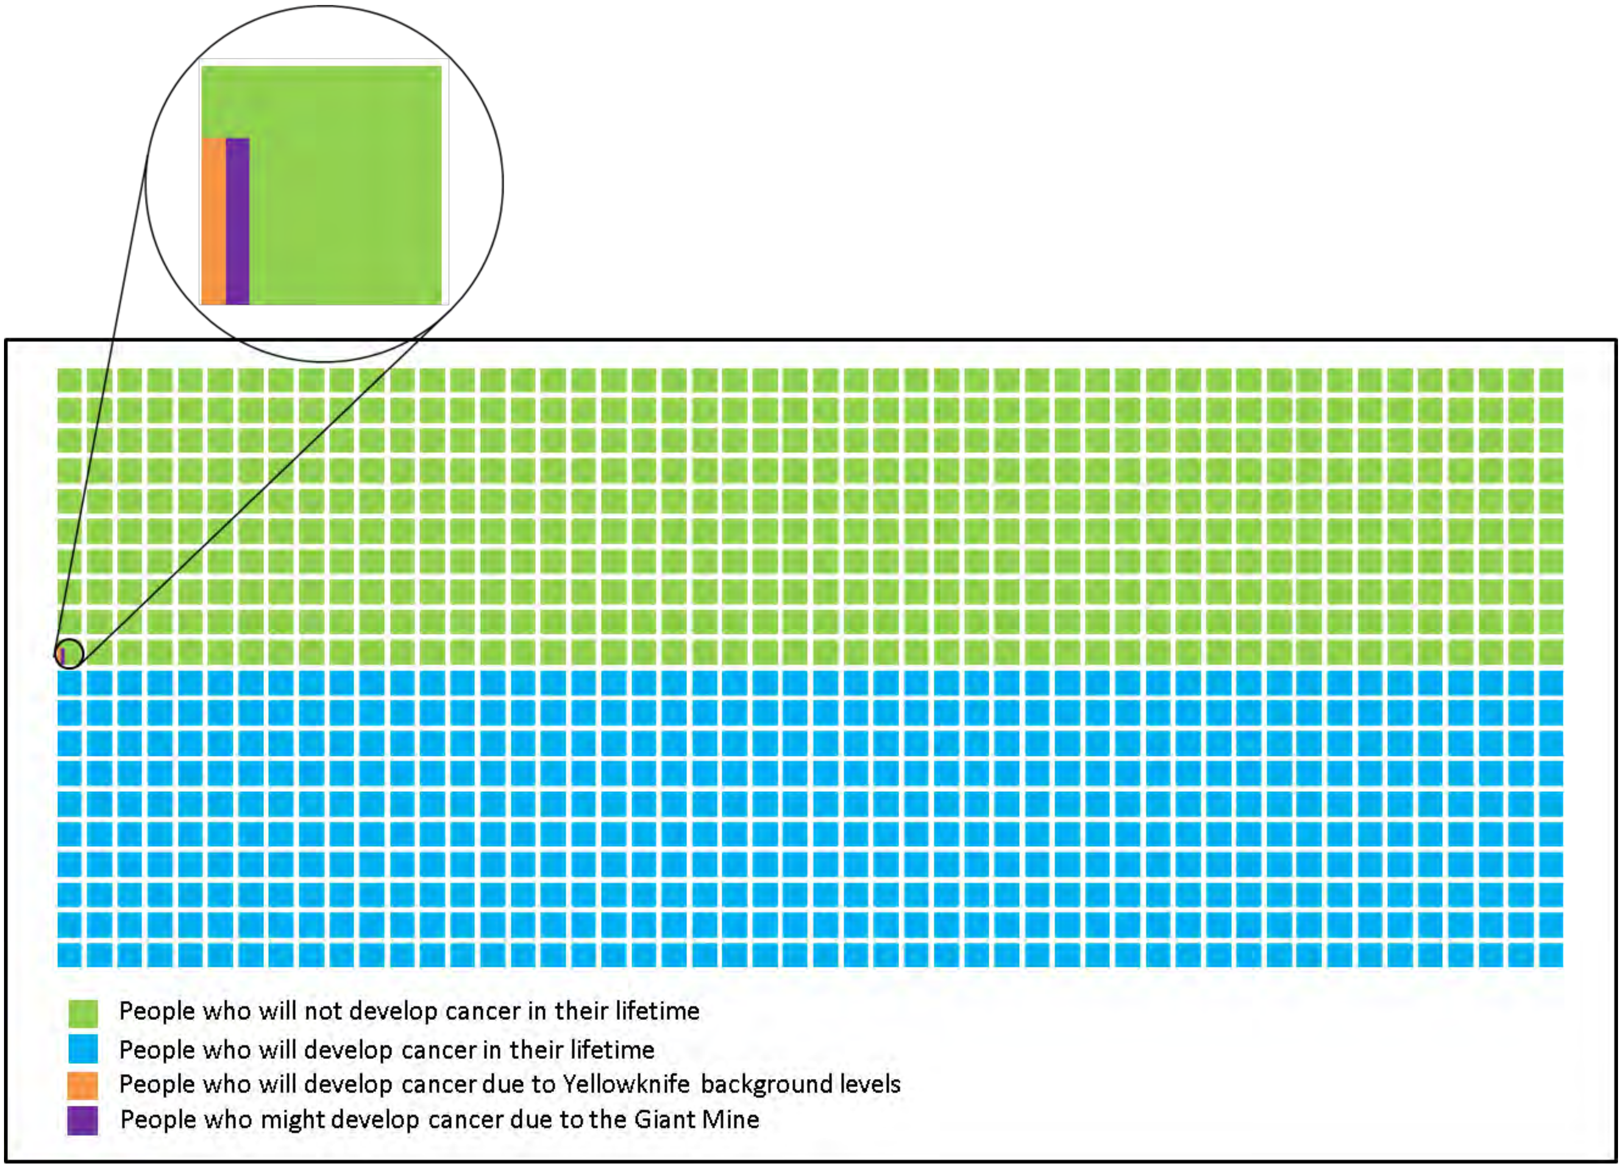
At the former Townsite location, the remedial activities will reduce arsenic concentrations in soil and, under a residential scenario (most restrictive land use), the risks are considered to be in the very low range.

As arsenic is considered to cause cancer, it is important to look at Canadian cancer statistics in order to provide a context to these risk values. The most recent cancer statistics reported by the Canadian Cancer Society (2017) indicates that 1 in 2 Canadians is expected to develop cancer during their lifetime. Figure 3.52 provides a schematic representation of the Canadian cancer risk and shows the incremental risk from the Giant Mine. Due to the small number of people in the various areas, only the risk from the entire Yellowknife area can be provided on the figure as an appropriate statistical representation.

The figure provides 1000 squares, each representing 1000 people in the Yellowknife area. Based on the Canadian cancer statistics, one half of these people will develop cancer (shown in light blue). Background risks are shown by the orange line and represent 7 in 100,000 people. The incremental risk for the entire area as a result of activities at the Giant Mine is shown by the dark purple line in the figure, and represents less than 1 person in 10,000 people developing cancer. This is the average risk across the entire Yellowknife area. In terms of the population of the City of Yellowknife, which by the 2016 census was 19,569 people, about 1 additional person in the population may develop cancer associated with arsenic exposure mostly associated with historical contamination across the Yellowknife area. Remedial actions at the Giant Mine will not alter the arsenic exposure across the Yellowknife area.

It should be noted that the nature of risk assessment is to generally over-estimate actual exposures. Therefore, actual cancer incidence associated with the Giant Mine may be less than indicated in Figure 3.52.

Figure 3.52 Schematic representing incremental cancer risks from Giant Mine



3.5.3 Sensitivity Analyses

The effect of a number of the assumptions made in the risk assessment was tested within the sensitivity analysis to determine the effect on the results. The results of all the analyses showed that the Ndilo resident was the most exposed person; therefore, the sensitivity analysis was carried out for the Ndilo resident with a typical country food diet, which represents the majority of the people in this community. The results of the assessment also showed that the risks from exposure to antimony and manganese were negligible. Therefore, the sensitivity analysis focused on arsenic exposure.

The assumptions that were tested were as follows:

- Country food – Average concentrations of arsenic were used in county foods as it was unlikely that people would eat all their country foods at the maximum concentration. Nonetheless, the sensitivity analysis examined the effect of people eating all their country foods at the maximum measured concentrations.
- Ptarmigan/Grouse – The concentration or arsenic in ptarmigan was an order of magnitude higher than concentrations measured in background (0.02 mg/kg ww vs. 0.004 mg/kg ww). Therefore, the sensitivity analysis considered that ptarmigan/grouse made up all the wild game that people ate.
- Berries – The assessment assumed that only 5% of berries would be obtained from Ndilo, as there were not enough berry bushes to supply the amount of berries that people indicated that they ate. The sensitivity analysis considered that people would get 100% of their berries from Ndilo.
- Moose – One moose sample obtained from the voluntary sampling had an arsenic level of 0.7 mg/kg ww and was found to be an outlier. Nonetheless, the sensitivity analysis examined the effect of consuming moose meat at this maximum arsenic concentration.
- "Hot spot" Remediation – There have been several "hot spots" identified in soils in the community of Ndilo particularly to the north of the community and at the school. The sensitivity analysis evaluated the impact of cleaning up the three highest "hot spots" in the Ndilo community.
- Indoor Dust – There were no indoor dust samples, and the assessment assumed that the indoor dust concentration was 70% of the outdoor soil concentration. This was the upper end of the range reported in the literature. Nonetheless, the

sensitivity examined the assumption that the indoor dust concentration was equal to the outdoor soil concentration.

- Bioaccessibility – For wild game, it was assumed that the bioaccessibility of arsenic from ingested game was 50% based on some studies on hare from the Yellowknife area. This is not an unreasonable value to use as not all the arsenic in meat is available. The sensitivity analysis examined the effect of using 100% arsenic bioaccessibility.

Figure 3.53 provides a summary of the results of the various sensitivity analyses for the Ndilo resident. Details and results are provided in Appendix I. The figure shows that the assumptions related to berries, ptarmigan, indoor dust, and bioaccessibility of arsenic in wild game have little effect on the results. For indoor dust, a number of assumptions were also made with respect to skin contact. These assumptions were not tested in the sensitivity analysis, as the testing of a dust assumption had no substantial effect on the results.

The assumptions related to the use of the maximum arsenic concentrations in wild food resulted in an increase in arsenic exposure, which is not surprising; however, the results were still within the low risk range. The consideration of the eating all moose meat at the high arsenic concentration also results in the risks just moving into the low risk range. The clean up of “hot spots” in the Ndilo community reduces the estimated risk levels.

Figure 3.54 shows the result of assuming that 100% of the arsenic in mushrooms was bioaccessible. As seen from the figure, the estimated risk levels do not change very much.

Figure 3.53 Estimated incremental lifetime cancer risk from arsenic – sensitivity assessments

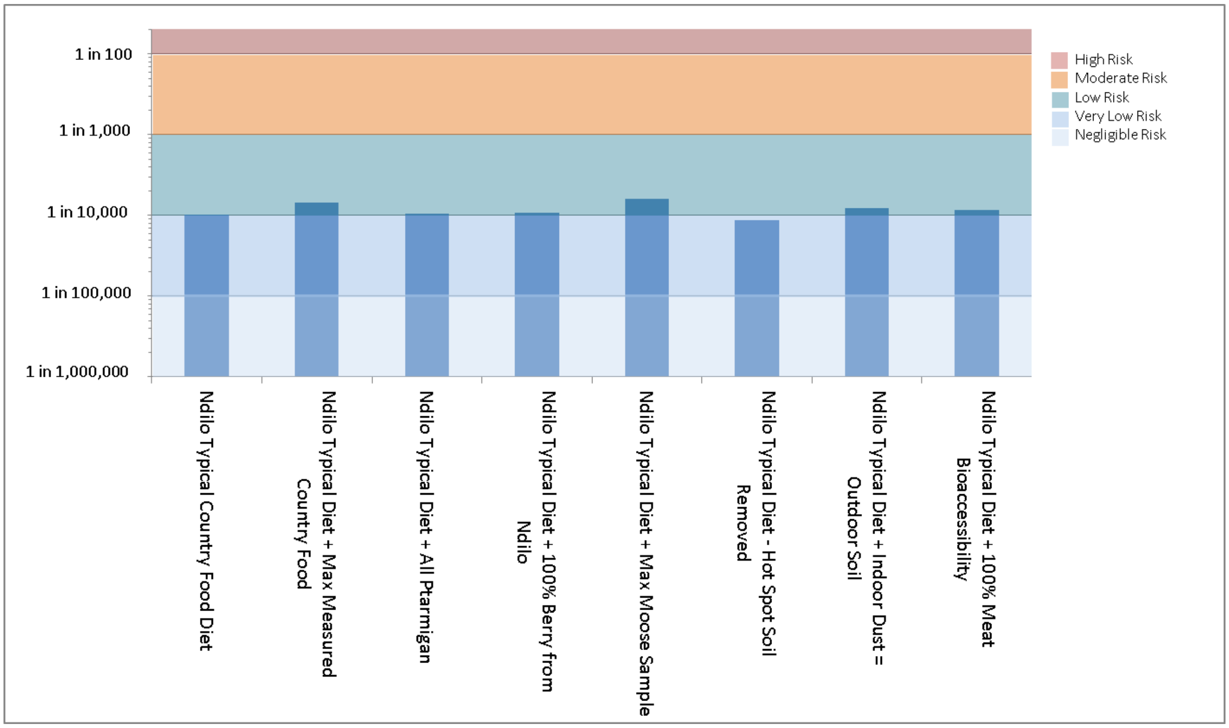


Figure 3.54 Estimated incremental lifetime cancer risk from arsenic – sensitivity assessment mushrooms

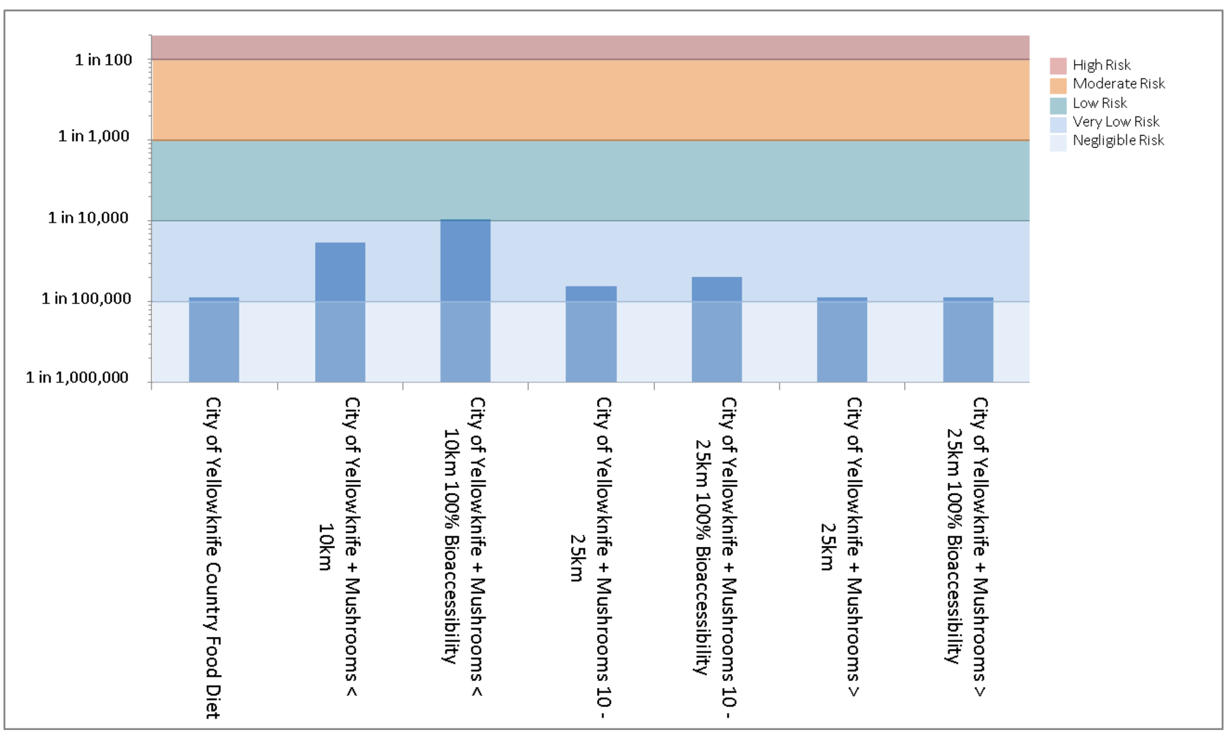
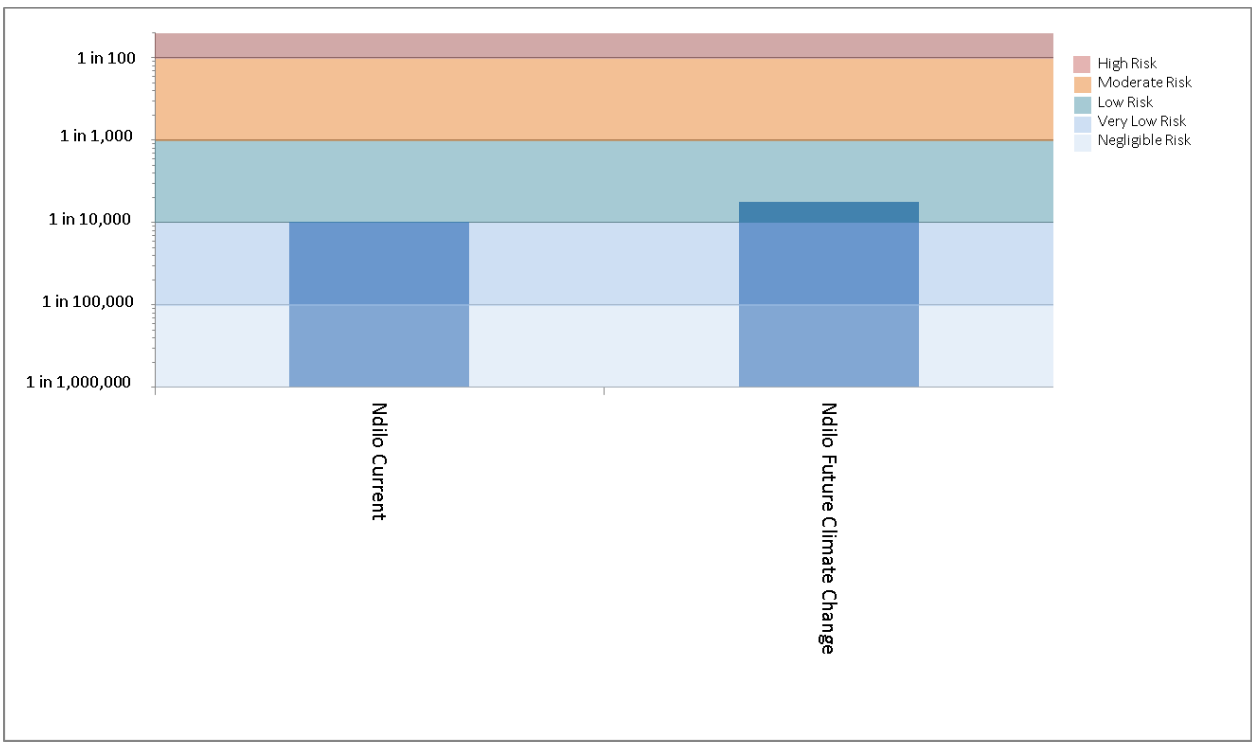


The effect of climate change on the future conditions at the Giant Mine is difficult to quantify. In general, the long-term meteorological data set for Yellowknife shows trends toward milder temperatures and more precipitation (INAC/GNWT 2010). The CCCSN assessment indicated that precipitation may increase by up to 15% over the next 50 years. For the purposes of the risk assessment, it was assumed that precipitation may increase by as much as 30% in 100 years. This could result in increased run-off and erosion. Therefore, in an effort to address climate change, the sensitivity assessment looked at the effect on the results if the water and sediment concentrations and, consequently, fish concentrations increased by 30% over the 100 year assessment period.

Figure 3.55 shows the results for the climate change scenario. The scenario looked at drinking water from Yellowknife Bay every day as well as eating fish and wading in the shallow sediments. The base case result for Ndilo is shown for comparison. The results show that with a consideration of climate change, the risks from exposure to arsenic following remedial activities at the Giant Mine are in the low end of the low risk range.

Figure 3.55 Estimated incremental lifetime cancer risk from arsenic – climate change



In summary, the sensitivity analyses show that the results of the risk assessment do not seem to change much when extreme (maximum) values are used for exposure calculations, rather than the average or typical values that more accurately reflect population exposures. This is because soil and indoor dust are the major sources of exposure within the various communities evaluated, and climate change or remediation activities at the Giant Mine will have no influence on levels of arsenic in soil and indoor dust.

3.5.4 Uncertainties

There are several areas of uncertainty in conducting a risk assessment due to the fact that assumptions have to be made throughout the assessment either due to data gaps, environmental fate complexities, generalizations of characteristics related to diet, and other human characteristics. An accounting of the uncertainty is provided to be able to place a level of confidence in the results. The magnitude and type of uncertainty are important in determining the significance of results. In recognition of these uncertainties, conservative assumptions were used throughout the assessment to ensure that the potential for exposure and risks would not be underestimated. The major assumptions are outlined below.

The COPC concentrations used in the assessment were based on measured data, when available, from the aquatic and terrestrial environments from a variety of sampling programs. The number of data points was limited for soils in Dettah and for the foods collected in the dietary program, which adds some uncertainty. Additional data collected in 2017 increased the data set for Dettah and for a number of foods and resulted in lower concentrations than those used in the assessment. This demonstrates the conservative nature of the assessment.

The use of reasonable maximum exposure concentrations, which were generally an upper estimate (95% UCLM) values of measured data, and within the sensitivity analysis some maximum measured concentrations were used, result in conservative estimates of exposure. Average concentrations of COPC were used for the country foods based on the measured data from the voluntary sampling. As shown in the Sensitivity Analysis in Section 3.5.3, the maximum concentrations were used to evaluate the influence of variations of concentration assumptions on exposure and risk calculations. Although maximum values did result in some increase in estimated arsenic exposure, few variables were overly influential besides soil an indoor dust concentrations and, therefore, the overall conclusion of low risk from arsenic exposure is considered valid.

Sediment COPC are somewhat mobile, as sediment moves within waterbodies, and, over time, sediment concentrations may decrease through sediment processes such as burial. Thus, the sediment concentrations as represented by an upper estimate of the mean (95% UCLM) may not represent the concentration of the COPC over the long term. Arsenic is known to be released from the sediments when there is not a lot of oxygen present, and, in these cases, the arsenic becomes mobile and the concentrations in the sediment may increase. The assumption of long-term exposures to the upper estimate concentration for antimony and manganese is likely to have overestimated actual exposures. However, in the case of arsenic, it is difficult to determine whether it is an overestimate or an underestimate. Nonetheless, the sediment pathway is a minor pathway of exposure and the overall conclusions of the risk assessment would not be changed.

There were no measurements for indoor dust and, thus, the assessment assumed based on literature studies that the indoor dust concentration was 70% of the outdoor soil concentration. Literature studies indicate that dust levels range from 30% to 80% of outdoor soil concentrations and, thus, the use of 70% is at an upper end of the studies. A sensitivity assessment was done in Section 3.3.7.1 assuming that the indoor dust concentration was equal to the outdoor soil concentration. This did not significantly affect the results. Thus, the evaluation of potential variation of concentrations in the indoor dust pathway does not substantially add to the exposure risk.

Site-specific bioaccessibility and speciation data were not available for antimony and manganese and, therefore, it was assumed that they were 100% bioaccessible. In addition, the oral bioavailabilities of antimony and manganese in soil, sediment, and water were generally assumed to be equivalent to the highly bioavailable forms used in the toxicity studies upon which TRVs were based. This would lead to an overestimate of exposure. For arsenic, assumptions were made for the bioaccessibility in soil and sediments based on measured data for soils and sediments. In addition, for wild game, it was assumed that the bioaccessibility from consumed meat was the same as the bioaccessibility measured in hare from the Yellowknife area based on a literature study (Koch et al. 2013). The assumption of 50% seemed reasonable; however as shown in Section 3.3.7.1, an assumption of 100% bioaccessibility from wild game meat was evaluated. This resulted in an increase in arsenic exposure; however, the risk from arsenic exposure was still low.

It was assumed that people in Ndilo would get 5% of their berries from around Ndilo and 95% of their berries from areas greater than 10 km from Giant Mine, as this is the current practice. A sensitivity analysis was conducted assuming 100% of berries were obtained from Ndilo. This is an unrealistic assumption, as there were not enough berry bushes to support the amount of berries people reported eating. Nonetheless, the results show that this assumption does not substantially change the results.

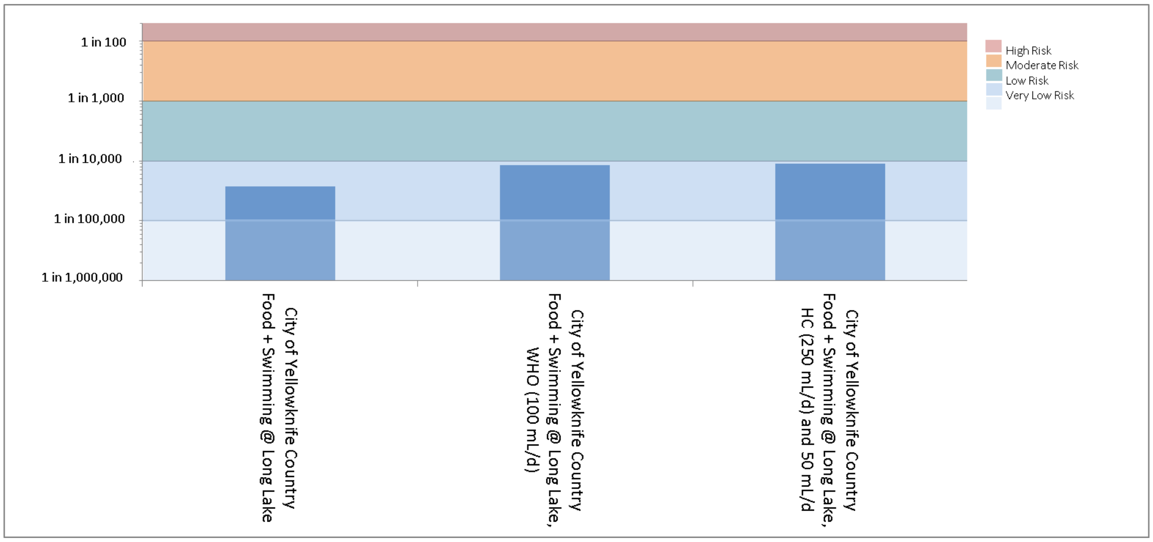
There were no background arsenic samples for organs and, therefore, the risks calculated from organ consumption represented the total risk and not the incremental risk, which is an overestimate. Additionally, there is double-counting in the consideration of the supermarket intakes, which were not reduced for the typical country food diet scenarios to account for the portion of the diet obtained from country foods. This leads to an overestimate of exposure for typical country food diet scenarios.

For the future conditions at the Giant Mine, all the soil samples were used to develop the concentrations. A number of these samples are in highly forested areas and wetlands that are difficult to access. Thus, the exposure point concentrations were overestimates of areas of the Giant Mine that would be accessible for recreational activities.

The human receptor characteristics are also a source of uncertainty. The use of single values for various characteristics to evaluate exposure may overestimate exposure. For example, it has been assumed that an adult weighs 70.7 kg, when in reality an adult is likely to weigh more, thereby reducing the daily intake on a body weight basis (Richardson and Stantec 2013).

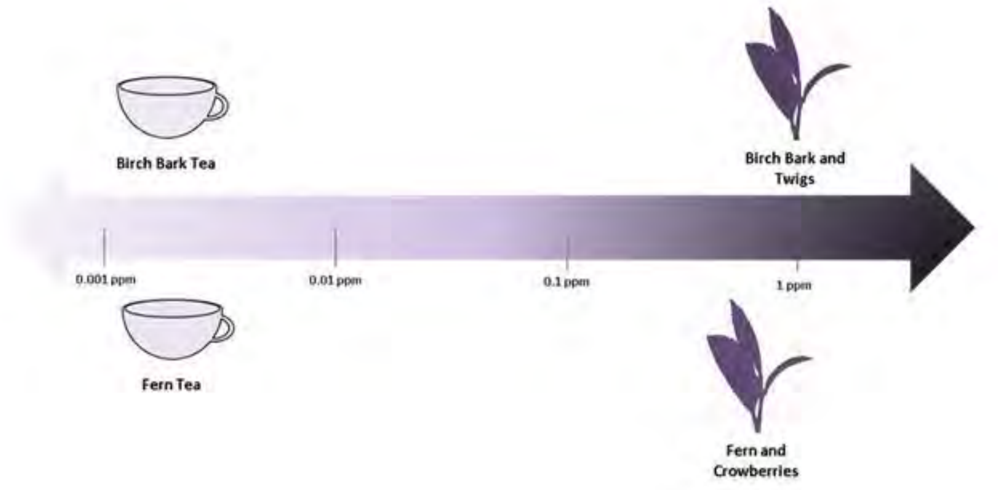
In evaluating swimming exposure in Long Lake, the assessment used incidental water ingestion intakes provided by the U.S. EPA (2011) of 21 mL/hr for and adult and 49 mL/hr for toddlers and children. Health Canada (2012b) in their guidelines for *Canadian Recreational Water Quality* use a value of 250 mL/d for a child swallowing water while swimming and the WHO (2006) uses a value of 100 mL/d. The uncertainty analysis considered these different amounts of water being swallowed and the results are presented in Figure 3.56. As seen from the figure, the increased amount of water swallowed while swimming increases the risk but it is still in the very low risk range.

Figure 3.56 Estimated potential exposures for different amounts of water swallowed while swimming



The amount of Labrador tea (leaves and stems) used to brew medicinal tea was assumed based on the interpretation from the dietary study. As the consumption of Labrador tea only represented a small fraction (generally less than 1%) of the intake for most of the COPC, it is unlikely that the uncertainty in the consumption of Labrador tea would change the results of the assessment. The concentration in the leaves and stems was used in the assessment. McAuley et al. (2016) analyzed samples of Labrador tea leaves and mint tea leaves as well as teas made from the leaves and found that concentrations of chemicals in the teas were orders of magnitude lower than in the vegetation. Thus the approach in the risk assessment is most likely an overestimate. In the summer of 2017, additional medicinal tea samples were collected and four samples were brewed into tea. Figure 3.57 shows a summary of the analytical concentrations. As seen from the figure, the measured leaf and twig samples had higher concentrations than the brewed tea samples. This is the same as the findings of McAuley et al. (2016) and indicates that the concentrations used in the evaluation of medicinal teas have been overestimated.

Figure 3.57 Comparison of arsenic concentrations in brewed tea samples with measured leaf and twig samples

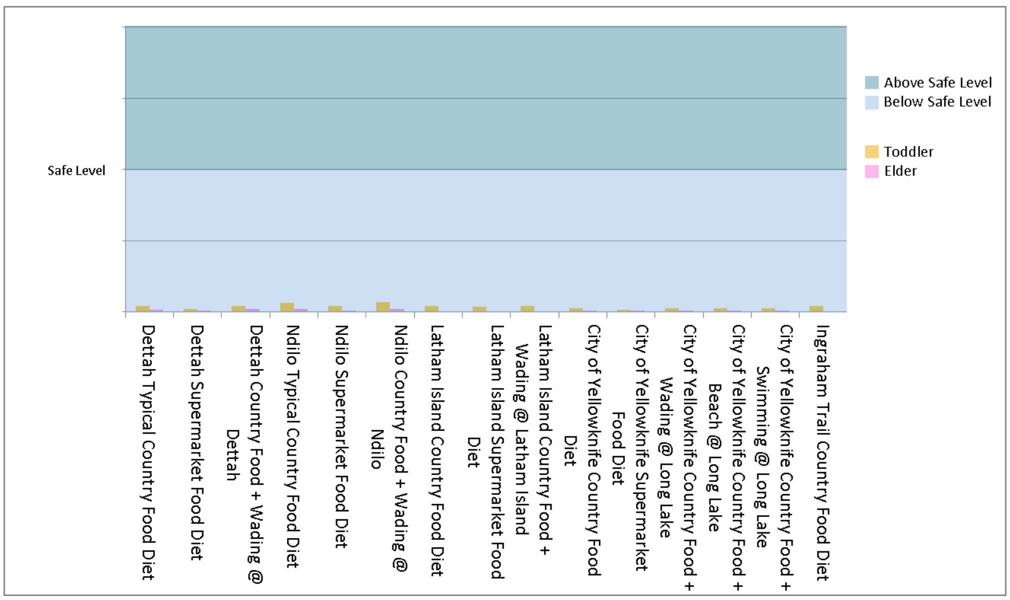


Exposure is averaged over a specified period, which is representative of the exposure frequency and duration. For soil and sediment exposures averaging was done over a shorter time period equal to the exposure duration. However, residents in the communities surrounding Giant Mine are exposed every day to COPC in indoor dust, drinking water and supermarket and country foods and shorter term exposures to soil and sediment outdoors during the summer are not isolated but are in addition to the on-going daily exposures. Therefore, these shorter term exposures increase the daily exposures during the summer period. Given that exposures occur every day it may be more appropriate to average the exposure over 365 days rather than use the shorter times that were used in the risk assessment. Thus, the approach used in the risk assessment results in overestimates of exposures via the soil and sediment pathways.

The TRVs are obtained from authoritative sources (e.g., Health Canada, U.S. EPA); nonetheless, they are always associated with uncertainty due to the extrapolation of testing on lab species (e.g., rats, mice, etc.) to field conditions as well as a range of receptors. Additionally, toxicity information for antimony, arsenic, and manganese was used regardless of its form in the test procedure, even though this may not be the same form in the environment (i.e., an oxide form compared to a more soluble form). In the derivation of cancer TRVs for arsenic, the linear extrapolation of data in the low-dose region of the dose-response curve is assumed to be sufficiently conservative to account for uncertainties related to the TRV. The use of an upper bound for the toxicity values ensures that the risk to humans is not underestimated. Currently, it is not possible or practical to develop approaches to evaluate the validity of the TRV assumptions on the overall assessment. As improvements occur in toxicological/human health research and assessments, the uncertainties may be reduced.

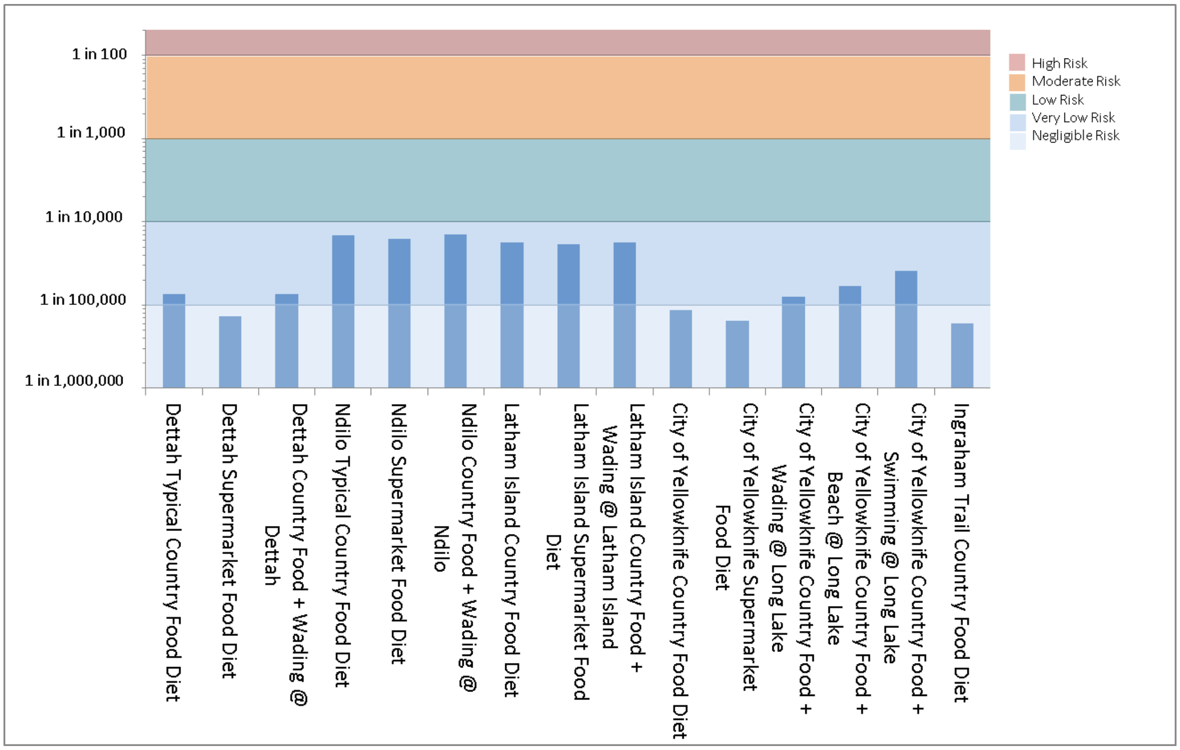
The antimony TRV of 4 x 10^{-4} mg/kg-d that was used in the risk assessment was obtained from the IRIS database (U.S. EPA 2017). Other international authoritative sources have suggested an alternate TRV of 6 x 10^{-3} mg/kg-d. The results associated with the alternate TRV are provided in Figure 3.58. It can be seen that these results are much lower than the results provided in Figure 3.34 of the risk assessment; however both figures indicate that the risks are below the safe level. Thus, the potential risks from exposure to antimony may have been over-estimated

Figure 3.58 Estimated potential exposures to antimony – alternate TRV



The arsenic TRV of 1.8 $(mg/kg\text{-}d)^{-1}$ for oral exposure used in the document was obtained from Health Canada (2010b), based on liver, lung and bladder cancers. As indicated in Appendix G, the IRIS database (U.S. EPA 2017) provides a TRV of 1.5 $(mg/kg\text{-}d)^{-1}$ based on skin cancer. The results associated with the alternate TRV for arsenic are provided in Figure 3.59 for the typical diet scenario. It can be seen that these results are much lower than the results provided in Figure 3.44 of the risk assessment and risks are in the negligible to low risk range. It should be noted that the endpoints are different for the two TRVs; however, the results of the arsenic evaluation remain more or less unchanged.

Figure 3.59 Estimated potential exposures to arsenic – alternate TRV



The effect cumulative of multiple COPC on risk was not evaluated in this assessment. When dealing with toxic chemicals, there is potential interaction with other chemicals that may be found at the same location. From a human health perspective, it has been established that synergism, potentiation, antagonism or additivity of toxic effects may occurs in the environment. A quantitative assessment of these interactions is outside the scope of this study and would be constrained, as there is not an adequate base of toxicological evidence to quantify these interactions. A simple qualitative assessment looking at the non-carcinogenic endpoints for humans indicates that there are no similar endpoints and, thus, risks are not considered to be additive. Therefore, the effects of multiple COPC on the assessment are anticipated to be negligible.

Table 3.12 provides a summary of the uncertainties and tries to assign a value to the uncertainty. It must be noted that these are approximations; however, in general it is accepted in the risk assessment community that the conservative assumptions used in the assessment generally result in overestimates of the risks by a factor of two to five. It can be seen from the table that, in general, the uncertainties used in the assessment lead either to an overestimate of exposures. Since soil and dust and food are the biggest contributors of exposure, overestimates in the assumptions for these components make the biggest effect on the results. Based on Table 3.12, the conclusions of the assessment are considered valid and reliable for the intended purpose.

Table 3.12 Summary of uncertainties in the HHRA

Uncertainty	Overestimate	Possible Underestimate or Neutral Effect	Comment
Limited data sets for soil at Dettah and Ingraham Trail.			Additional soil samples at Dettah and Ingraham Trail presented in Appendix P showed that the EPC concentrations in the assessment were higher than the EPC with the new data. The data indicates that concentrations may be overestimated by a factor up to 2.
Development of future EPCs on Giant Mine.			Soil is one of the biggest contributors to exposure. The future soil EPCs at the Giant Mine may be overestimated by a factor of two to five as they were based on some of the disturbed soil areas.
Use of reasonable maximum exposure concentrations to characterize exposures.			The use of the 95% UCLM to represent exposures for most media with the exception of food may overestimate exposures by a factor up to two.
Use of average concentrations in country food samples.			The use of the average concentration in country foods is an appropriate value to be used; however if the maximum concentration was used the exposure may be underestimated by a factor of two.
Use of upper bound concentrations of in sediments.			Sediments represent a minor exposure pathway and thus the values used for sediment exposures do not change the results.
Use of Labrador tea leaves and twigs to represent concentrations in tea.			Measured data from twigs and leaves in comparison to tea presented in Appendix P indicate that medicinal tea concentrations used in the assessment may be overestimated by a factor of two to four. However medicinal tea is not a main exposure pathway.
No background concentrations for arsenic in organs.			Organs do not represent a major exposure pathway and thus this overestimate does not affect the results.
No adjustment in supermarket food intakes for typical country food diet scenarios			This results in an overestimate of exposure for antimony and manganese in particular. All risks from exposure to antimony and manganese are below the safe level therefore results will not be changed.
Assumption of 100% bioaccessibility for antimony and manganese.			It is known that metals are not fully absorbed in the digestive system. This may overestimate exposure by a factor of two to 10. All risks from exposure to antimony

Uncertainty	Overestimate	Possible Underestimate or Neutral Effect	Comment
			and manganese are below the safe level therefore results will not be changed.
Use of single values for human receptor characteristics such as body weight of 70.7kg.			People are different and weigh different amounts and drink various amounts of water etc. This may result in an overestimate of exposure by a factor up to two.
Food consumption rates for humans based on data from dietary survey.			Studies have shown that people indicate that they eat more in dietary surveys. This may result in an overestimate of exposure by a factor up to two.
Averaging of soil and sediment exposures over exposure duration			As people in Yellowknife are chronically exposed to arsenic, the approach to averaging the soil and sediment exposures tends to overestimate exposures by a factor of two to three.
Safety factors used by agencies in developing toxicity values.			Regulatory agencies use safety factors when they develop toxicity values to try to make sure that sensitive people such as toddlers and elderly are protected. This tends to overestimate risks by a factor of three to 10.
Synergism, potentiation, antagonism, additivity of toxic effects.			Toxicity endpoints were not the same and therefore this may be a neutral effect.

4.0 ECOLOGICAL RISK ASSESSMENT

The ERA considers both the aquatic and terrestrial environments at the Giant Mine. For the aquatic environment the focus is on the on-site environment with consideration also given to the off-site environment immediately downstream of Baker Creek (i.e., Back Bay). North Yellowknife Bay and South Yellowknife Bay were also considered as appropriate in the assessment; however, it should be noted that CCME aquatic quality guidelines are met in these locations. For the terrestrial environment, only exposure on the Giant Mine is included in the assessment.

4.1 Summary of Previous Studies

There are two different ecological assessments that were considered as the foundation for the development of the Problem Formulation:

- Ecological Risk Assessment for Giant Mine (SENES 2006)
- Assessment of Aquatic Resources in Baker Creek (Golder 2013a)

These studies were used to select the receptors and exposure pathways used in the assessment and are discussed in Appendix A. There are also a number of biological studies that have been conducted at the Giant Mine that provide analytical data in various media and biota that were considered in the ERA.

The SENES (2006) study concluded that, for current conditions, there was some potential for fish to be impacted within Baker Creek, but more biological sampling was recommended to allow for a Weight of Evidence (WOE) approach. Further studies of Baker Creek sediments were also recommended to examine effects on benthic invertebrates. The diversity of benthic communities in parts of Back Bay and North Yellowknife Bay may also be affected by existing levels of arsenic, but it was noted that this situation will gradually improve as sediments with elevated arsenic levels are buried over time and covered with cleaner material. In the terrestrial environment, no adverse effects were expected on wildlife such as bear, caribou, grouse, and wolf. Potential adverse effects on hare were identified and terrestrial vegetation was the primary source of exposure. Potential effects were also identified for muskrat and mink, primarily from arsenic in water, sediment, and aquatic plants. A field investigation for muskrat was undertaken on Baker Creek to support the risk assessment. The measured tissue levels and field evidence from the biological survey indicated that there are active dens that support a substantial population of muskrat on Baker Creek, and it is unlikely that the presence of arsenic in the sediments of Baker Creek was causing serious adverse effects on populations of small terrestrial mammals with a significant aquatic based diet.

Golder completed an assessment of the aquatic community in Baker Creek (Golder 2013a). The overall objective of the report was to support decision-making activities with respect to the remediation options for Baker Creek. It was found that approximately 30% of the locations examined were classified as having significant adverse effects, 45% of the locations had potential adverse effects, and 25% of the locations had negligible adverse effects. There was no gradient of potential effects and toxicity "hot spots" were located throughout Baker Creek. Benthic invertebrates were found at all locations, even locations with elevated concentrations; thus, recolonization of sediments by benthic invertebrates is occurring. The elevated concentrations in the sediment are also accessible to fish and other organisms in Baker Creek.

4.2 Description of the Environment

4.2.1 Terrestrial Environment

As discussed in the Environmental Assessment document (INAC/GNWT 2010), the terrestrial environment is broadly defined as being the Taiga Shield. A chief defining ecological characteristic of the Taiga Shield is the heterogeneous distribution of trees, which ranges from clumps of forest in areas with deeper soil to widely spaced stunted trees near the northern treeline. The extreme climate with long, cold winters, little precipitation, and few nutrients results in limited tree growth. Large areas of permafrost restrict root growth for trees and shrubs. Another key feature of the Taiga Shield is the large number of small to large lakes distributed across the ecoregion. While many lakes are isolated or connected to local drainage systems, major drainage systems drain to Great Slave Lake and ultimately to the Arctic Ocean or to Hudson Bay through the Thelon River system.

The Giant Mine consists of largely discontinuous permafrost and the forests consist primarily of jack pine and black spruce stands on nutrient-poor soils. The physical topography consists predominantly of exposed bedrock with discontinuous till and thin soils over bedrock. Mixed stands of jack pine, aspen, white spruce, and birch are also common forest types within the region. Wetlands are a dominant feature.

Bird habitats at the Giant Mine were categorized into four types: uplands, wetlands, riparian areas, and disturbed areas (Golder 2015d):

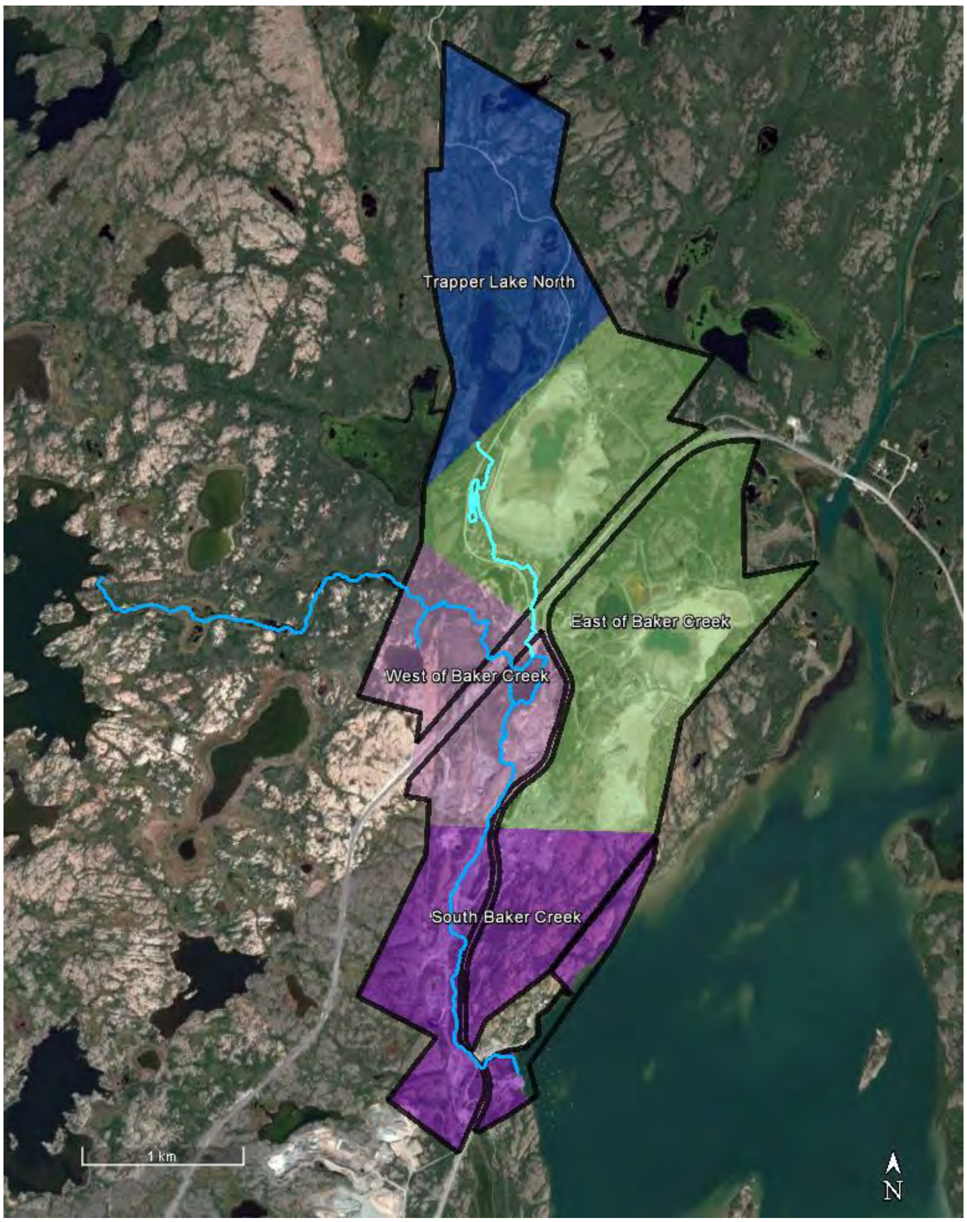
- Uplands: Comprises mesic forest (white spruce, paper birch, willow, and Labrador tea), scrub forest (paper birch, juniper) and rock outcrops (sparsely vegetated with bearberry, common juniper, and various grasses). Provides habitat for songbirds, raptors, owls, grouse, raven, magpie, gray jay, and finches.
- Wetlands: Characterized by cattail and sedge vegetation. Water sedge makes up 75% of the sedge community. Had the greatest diversity in birds including grebes, loons, waterfowl, water birds, shorebirds, gulls, terns, and passerines. The largest area of wetlands is around the perimeter of Trapper Lake, which has also been reported to have high abundance and diversity of wetland birds.
- Riparian Areas: Restricted to the seasonally flooded banks of the northern end of Baker Creek. This area is non-forested and has willow and bog birch shrubs as well as horsetail, dwarf raspberry, and Canada blue-joint. Representative species from all bird groups may use riparian areas, but they are especially important for songbirds.
- Disturbed Areas: These areas include meadow, vegetated, and un-vegetated areas. Previous studies showed that gulls and terns preferred disturbed sites over undisturbed sites, but the use of disturbed sites by other birds was low.

In 2016, Golder conducted a survey of the wildlife use of the Giant Mine and surrounding area using winter track counts, remote cameras, and site surveillance surveys (Golder 2016k). The survey targeted disturbed areas of the site, undisturbed areas of the site, and off-site areas.

Tracks from eleven wildlife species, or groups, were observed during the track counts. The most common wildlife tracks observed were coyote, red fox, snowshoe hare, red squirrel, ptarmigan, and other small mammal species. Other small mammal species include mice, voles, or shrews. Ptarmigan species were most likely willow ptarmigan (*Lagopus lagopus*) but may also have included rock ptarmigan (*Lagopus muta*). Wildlife incidentally observed during the counts included ptarmigan and raven. The most common animal photographed on the remote cameras was red fox. The camera, which was set up on an undisturbed area of the Giant Mine, photographed red fox, snowshoe hare, ptarmigan, and lynx. The site surveillance surveys were conducted on targeted site facilities. The highest frequency of wildlife observed was the Akaitcho Shaft; observations of wildlife were relatively rare at all other locations.

For the ERA, the Giant Mine was subdivided into four quadrants as shown on Figure 4.1. The majority of the disturbed areas are in the East of Baker Creek area (mill, roaster, North, Central, South Tailings ponds and water management ponds). Trapper Lake North area is relatively undisturbed and is expected to have the highest occurrence of waterfowl due to the presence of wetlands around the perimeter of Trapper Lake (Cygnus Environmental 2005). West of Baker Creek is mostly undisturbed regions, including natural wetlands or ponded water. In addition, there are several pits in close proximity to Baker Creek. Baker Creek is discussed as part of the aquatic environment.

Figure 4.1 Terrestrial on-site quadrants considered for ERA



4.2.2 Aquatic Environment

The aquatic environment evaluated in the ERA is Baker Creek on the Giant Mine lease area and immediately downstream of the site in Yellowknife Bay (Back Bay/North Yellowknife Bay).

4.2.2.1 Baker Creek

As discussed in Section 1.0, the lower portion of Baker Creek (approximately 3.5 km in length) that flows through the Giant Mine lease area has been divided into seven reaches (Reach 0 to 6) based on major changes in creek hydraulics or channel conditions (INAC/GNWT 2010). Reach 0 is located at the mouth of Baker Creek, where it flows into Yellowknife Bay (Back Bay) behind a constructed breakwater. Reach 6 includes Baker Creek Pond, where mine effluent was discharged during mine operations and where treated effluent is currently discharged seasonally (typically during open water between July and September).

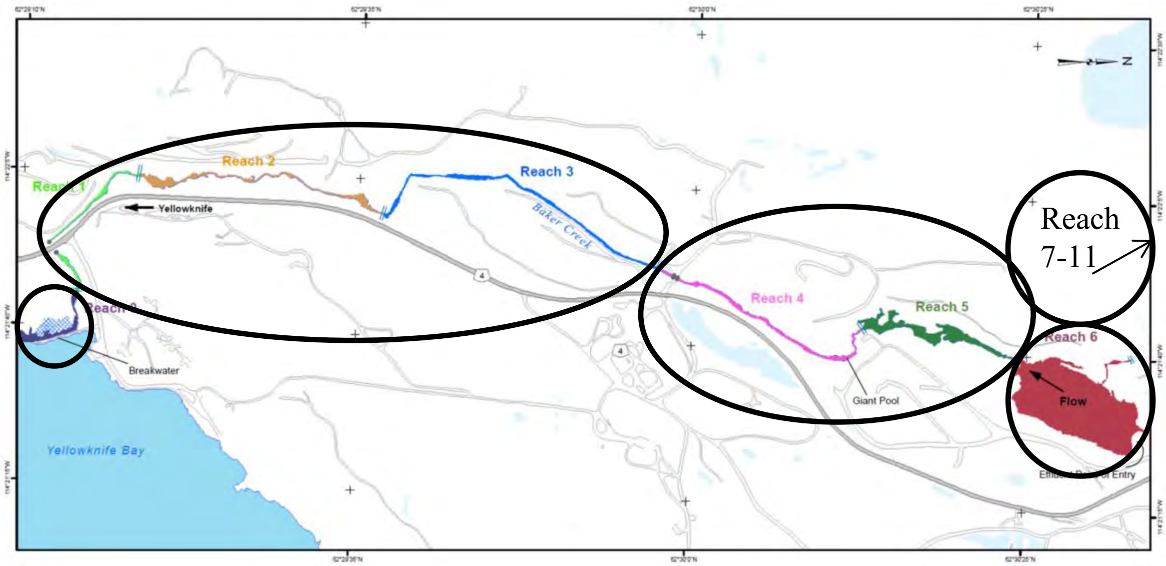
For the purposes of the ERA, Baker Creek was sub-divided into five different segments as shown in Figure 4.2:

- Reach 0;
- Reach 1-3;
- Reach 4-5;
- Reach 6; and,
- Reach 7-11.

There have been a number of studies documenting the presence of fish in Baker Creek, but it is not known whether they overwinter in the creek as there have been no formal winter studies conducted.

As an emergency flood prevention measure, Reach 4 was realigned into a new channel in the summer of 2006 to mitigate against the possibility of surface water flow reaching the underground mine workings in the area around Mill Pond (INAC/GNWT 2010). Studies conducted since the realignment of Reach 4 have shown that the modifications markedly improved the spawning success of arctic grayling within Baker Creek in the spring. The large gravel present in the creek bed is well-suited for concealing eggs until they hatch, and Baker Creek is the only identified grayling spawning habitat in the Yellowknife area. Baker Creek has been deemed a “closed fishery” by the Department of Fisheries and Oceans in the hopes of restoring the arctic grayling population.

Figure 4.2 Segments of Baker Creek



In August 2014, a preliminary assessment of the plant community structure along Baker Creek was initiated (Stevens et al. 2015). The goals were to identify patterns in plant community composition. Six sites were sampled along Baker Creek and two sites outside of the creek, Pocket Lake and a reference site on the Yellowknife River (although limitations in the use of Yellowknife River as a reference location were discussed). Species richness, density, and diversity were determined for each site. Principal Components Analysis (PCA) was employed to identify relationships between plant community structure and site abiotic characteristics.

A total of 32 plant taxa were identified, including 19 native taxa, 3 introduced taxa, 8 taxa of unknown origin, and 2 sensitive species (*Potamogeton pecitnatus* and *Alisma triviale)*. There were no clear patterns in species diversity and evenness; however, both tended to decrease moving from Reach 6 to Reach 0. The PCA suggested a correlation between water quality and plant community structure. Reach 4 was unique among the sites, with several species found only in this reach which was likely due to realignment and revegetation efforts (Stevens et al. 2015).

Pocket Lake, the small headwater lake (4.8 ha) located in the southern portion of the Baker Creek watershed, and Trapper Lake, in the northern part of the site, are not considered within the ERA, as the mandate of this ERA is to evaluate the potential impact of the GMRP, which will not impact these lakes.

4.2.2.2 Tailings Ponds and Water Treatment Facility

There are some other areas of water at the Giant Mine. It should be noted that the tailings ponds on the site are dry with the exception of a small area in the North Tailings Pond and the Northwest Tailings Pond, which is used as part of the water management system.

The Northwest Tailings Pond, as well as the Settling and Polishing ponds, are part of the active engineered water treatment system and, thus, are not considered in the ERA. The tailings ponds will be remediated and are not explicitly considered within the ERA. Additionally, bird surveys conducted at the Giant Mine indicated that disturbed tailings areas and associated water bodies were not used extensively by waterfowl, likely due to the ample selection of undisturbed water bodies adjacent to the site (Golder 2016l).

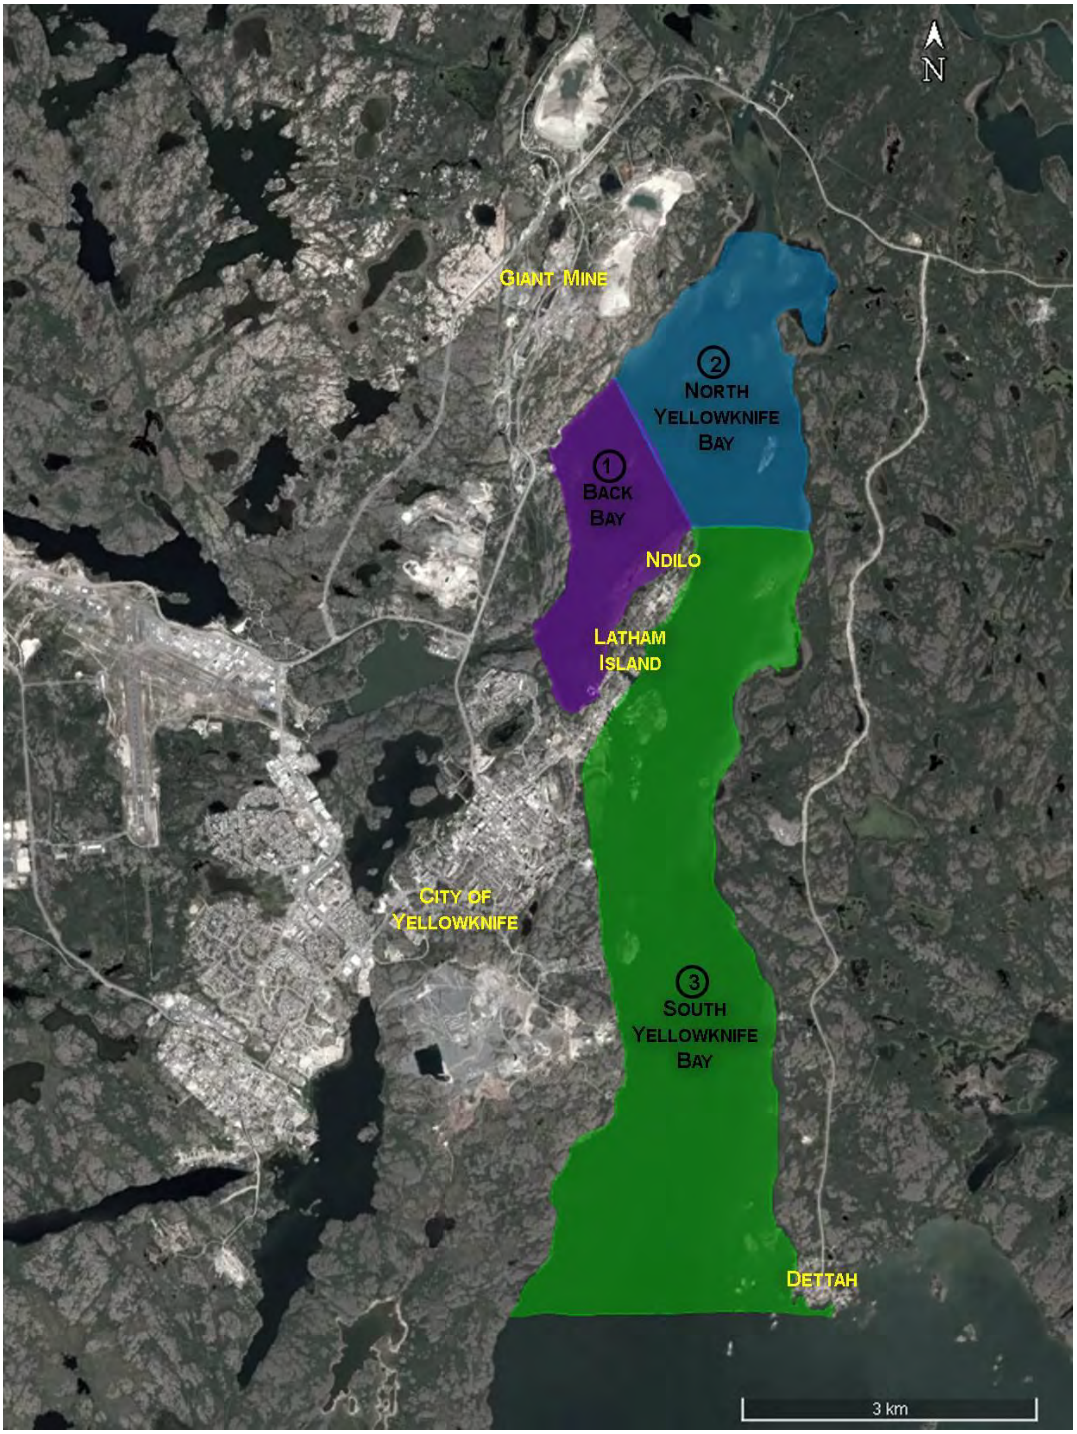
4.2.2.3 Yellowknife Bay on Great Slave Lake

Yellowknife Bay on Great Slave Lake is located directly adjacent to the Giant Mine and receives runoff from the site and treated water indirectly from Baker Creek.. For the ERA, Yellowknife Bay was been divided into three large segments as shown in Figure 4.3. The ERA focuses on the Back Bay section of Yellowknife Bay. This location is immediately downstream of Baker Creek and will receive the treatment plant effluent once the discharge is relocated.

The DAR (INAC/GNWT 2010) summarized some early studies conducted on Yellowknife Bay. It was reported that a spring bloom of phytoplankton in Yellowknife Bay occurred with the onset of light in the spring and continued growth until the end of October. The standing crop of phytoplankton in summer was related to surface water temperature and nutrient levels. Benthic and phytoplankton species were more abundant in the littoral zone than in deeper areas and were dominated by oligochaetes, molluscs, chironomids, and amphipods. The differences in composition, structure, and density of the benthic populations were related to the abundance of the algae attached to the bottom substrate.

A study on the benthic invertebrates showed the continuing effects of arsenic-contaminated sediments on the benthic community in North Yellowknife Bay (Golder 2005). The invertebrate communities were dominated by amphipods, clams, midges, and oligochaetes. Invertebrate abundance, richness, and metal-sensitive invertebrate abundance were negatively correlated with arsenic levels in sediments.

Figure 4.3 Segments of Yellowknife Bay



Stantec (2015c) conducted a habitat assessment of the foreshore tailings area (FTA) of Yellowknife Bay. They found sandy substrates nearest to the shore (depths 0.5 to 3 metres) that were associated with tailings deposits. Due to the low organic carbon and high metal concentrations, there is likely poor habitat for benthic invertebrates. Between two and eight metres, the habitat was bare, with fine substrates (primarily silt and clay) and very patching macrophytes. In part of the study area (between 3 m and 6 m), there were dense standing macrophytes. There are expected to be bivalves and other benthic invertebrates in these two habitats.

As reported in the DAR (INAC/GNWT 2010), studies of fish communities in the lakes around Yellowknife show that the species present are typical of cold, northern lakes with low productivity. The DAR (INAC/GNWT 2010) summarized the results of a survey of fisheries in the North Slave region of the NWT which reported 24 fish species in Great Slave Lake (Table 4.1). The fish species represent several trophic levels and a wide array of benthic and pelagic niches. For example, northern pike utilize the shallow shoreline areas for spawning and rearing. Young-of-the-year walleye also migrate into the nearshore areas for rearing. These areas contain an abundance of food for northern pike and walleye (e.g., other small fish), while aquatic vegetation provides protective cover.

Table 4.1 Inventory of fish species present in Great Slave Lake

Common Name	Scientific Name
Arctic Grayling	*Thymallus arcticus*
Arctic Lamprey	*Lampetra japonica*
Burbot	*Lota lota*
Chum Salmon	*Onchorhynchus keta*
Deepwater Sculpin	*Myoxocephalus quadricornis thompsoni*
Emerald Shiner	*Notropis atherinoides*
Flathead Chub	*Platygobio gracilis*
Goldeye	*Hiodon alosoides*
Inconnu	*Stenodus leucichthys*
Lake Chub	*Couesius plumbeus*
Lake Cisco	*Coregonus artedi*
Lake Trout	*Salvelinus namaycush*
Lake Whitefish	*Coregonus clupeaformis*
Longnose Sucker	*Catostomus catostomus*
Ninespine Stickleback	*Pungitius pungitius*
Northern Pike	*Esox lucius*
Round Whitefish	*Prosopium cylindraceum*
Slimy Sculpin	*Cottus cognatus*
Spoonhead Sculpin	*Cottus ricei*
Spottail Shiner	*Notropis hudsonius*
Trout Perch	*Percopsis omiscomaycus*
Walleye	*Stizostedion vitreum vitreum*
White Sucker	*Catastomus commersoni*
Yellow Perch	*Perca fluviatilis*

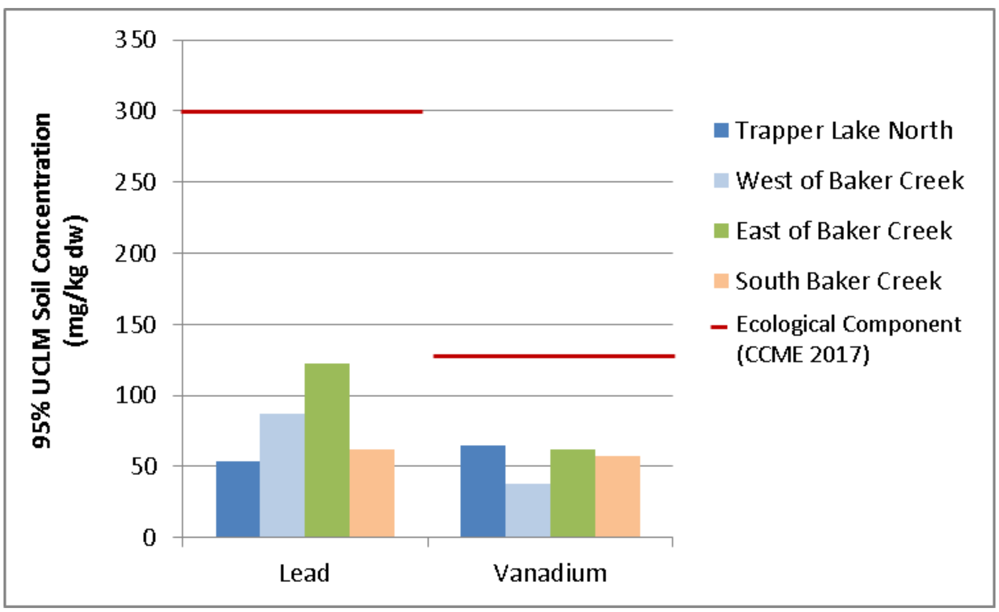
4.3 Problem Formulation

4.3.1 Hazard Identification

The initial COPC screen to identify COPC for the ERA was described in detail in Appendix D and summarized in Section 2.2.

A qualitative assessment was carried out for the concentrations of the COPC in the terrestrial and aquatic environments that need to be considered in more detail in the ERA. This qualitative assessment involved the comparison of concentrations in soil and water to ecological guidelines and/or background. The details of the qualitative assessment are provided in Appendix K. Figure 3.2 provides a representation of the soil screening process. As seen from the figure, the lead and vanadium concentrations in soil are below the ecological component of the applicable guidelines in all quadrants of the Giant Mine site. This represents a qualitative assessment and therefore lead and vanadium are not quantitatively evaluated in the risk assessment for soil.

Figure 4.4 Summary of qualitative analysis for lead and vanadium in soil



Further investigation was also undertaken for barium, potassium, and strontium in surface water. No guidelines are available for these COPC during the initial screening process; however, other toxicity values exist and were used to determine if they should be considered further (see Appendix K). Maximum measured concentrations of barium, potassium and strontium were compared to these toxicity values and all measured levels were below the identified toxicity values in Baker Creek and Yellowknife Bay, therefore these COPC were not quantitatively evaluated in the risk assessment for surface water.

Additional investigation of cadmium, cobalt, cyanide, and iron involved a review of the surface water data in Baker Creek to compare concentrations measured upstream (Reach 8 to 11, representative of baseline conditions) as compared to the rest of Baker Creek which have inputs from the effluent treatment plant as well as runoff from the site. Statistical tests indicated that the concentrations of cadmium, cobalt, cyanide, and iron in the upper reaches of Baker Creek are the same as those in the lower reaches. For this reason, cadmium, cobalt, cyanide, and iron are not considered further in the risk assessment for surface water in Baker Creek. Similarly, the copper concentrations in the lower reaches of Baker Creek are below baseline conditions. For this reason, copper is not discussed further with respect to surface water in Baker Creek. For further details, see Appendix K.

Therefore, the final list of COPC for the Giant Mine ERA is provided in Table 4.2. Chloride and sulphate are considered in the future in Yellowknife Bay due to the relocation of the water treatment plant effluent via outfall directly into Yellowknife Bay near Baker Creek outlet.

Table 4.2 Summary of final list of constituents of potential concern for the ecological risk assessment

Soil	Surface Water/Sediment	
ERA	**Yellowknife Bay – ERA**	**Baker Creek - ERA**
Antimony Arsenic Copper Manganese Zinc	Antimony Arsenic Chromium (*sed) Copper (*sed) Chloride (future only) Sulphate (future only)	Antimony Arsenic Cadmium (*sed) Chloride Chromium (*sed) Copper (*sed) Lead (*sed) Mercury (*sed) Sulphate Zinc (*sed)

Note: Arsenic in Yellowknife Bay was measured below the guidelines for protection of aquatic life but was retained due to community concerns; *sed – identified based on the sediment screen only.

4.3.2 Receptor Identification

4.3.2.1 Selected Receptors

It is neither practical, nor necessary, to individually assess each wildlife species that may potentially occupy, visit, or live near areas impacted by Giant Mine. Instead, a subset of terrestrial and aquatic wildlife receptors of concern that may be exposed to COPCs from Giant Mine were selected by focusing on receptors that are:

- indigenous to the area and would be potentially exposed to COPCs at the Giant Mine;
- most likely to receive the greatest exposure to COPCs due to their habitat, behavioural traits, and home range;
- representative of various levels in the trophic web (e.g., carnivore, herbivore, insectivore);
- potentially at risk because they have been classified as being rare or endangered (i.e., species of conservation concern); and
- culturally important.

The following section discusses the receptors that were selected to represent the biota that use the Giant Mine. These receptors represent a range of different diet types and trophic levels. For lower trophic levels, the receptor is defined at the community level. The selection of the receptors to be included in the aquatic and terrestrial environments was based on an understanding of the Giant Mine, as well as consideration of the previous assessments and discussions with stakeholders (WG members and GMAC).

Aquatic Receptors

Table 4.3 provides the ecological receptors selected in the aquatic environment. Further details on the selection of these receptors can be found in Appendix J.

Table 4.3 Ecological receptors selected for the aquatic environment

Aquatic Receptor Group	Aquatic Receptor Type	Selected Receptor
Water column organisms	Phytoplankton	Phytoplankton Community
	Zooplankton	Zooplankton Community
Benthic Invertebrates	Benthos Community	Benthic Invertebrate Infaunal Community
Fish	Benthivorous Planktivorous Piscivorous	Stickleback; Sculpin Arctic Grayling Northern Pike
Mammal	Herbivorous Insectivorous Piscivorous	Muskrat Bat (Little Brown Myotis) Mink
Bird	Herbivorous Insectivorous Piscivorous	Mallard Barn Swallow Horned Grebe, Osprey, Merganser

Terrestrial Receptors

The results of the previous ERA determined that large mammals were not at levels of unacceptable risk from exposure at the Giant Mine due to their wide home range. Therefore, the focus of this ERA is on mammals and birds with small home ranges. Based on feedback received from stakeholders (ECCC), the shrew and great horned owl were added to the assessment. There was also a suggestion to include an American robin, but it was determined that the ptarmigan and swallow would encompass the exposure by this receptor. Further details on the selection of these receptors can be found in Appendix J.

Table 4.4 provides the ecological receptors selected for the terrestrial environment. Further details on the selection of these receptors can be found in Appendix J.

Table 4.4 Ecological receptors selected for the terrestrial environment

Terrestrial Receptor Group	Terrestrial Receptor Type	Selected Receptor
Vegetation	Vegetation Community	Vegetation Community
Mammal	Herbivorous Insectivorous Carnivorous Omnivorous	Snowshoe Hare Bat (Little Brown Myotis), Masked Shrew Lynx Deer Mouse, Fox
Bird	Herbivorous Insectivorous Carnivorous	Willow Ptarmigan Barn Swallow Peregrine Falcon, Great Horned Owl

4.3.3 Receptor Exposure Pathways and Characteristics

The receptors selected for the risk assessment cover a range of diets and trophic levels. The diet composition for the mammals and birds are shown schematically in Figure 4.5 (birds in the aquatic environment), Figure 4.6 (mammals in the aquatic environment), Figure 4.7 (birds in the terrestrial environment), and Figure 4.8 (mammals in the terrestrial environment).

Appendix J provides further details on receptor exposure pathways, as well as a summary of the detailed receptor characteristics, including, for example, body weight, amount of food consumed, and diet composition. These were taken from FCSAP guidance where available and augmented by other literature as needed.

4.3.4 Conceptual Site Model

A CSM provides a picture to show the ways that the COPCs move from the soil, sediment, and water and the ways that the different pathways and receptors are being evaluated in the risk assessment. The picture in Figure 4.9 is a simplified version of the interactions and not all receptors and pathways are shown. Additional information is provided in Appendix K.

There is an extensive database of information that was the basis of the ERA. The COPC to be carried forward through the ERA were summarized in Section 4.3.1, the ecological receptors selected to be included were provided in Section 4.3.2, and Section 4.3.3 summarized how these receptors are connected to the environment (pathways).

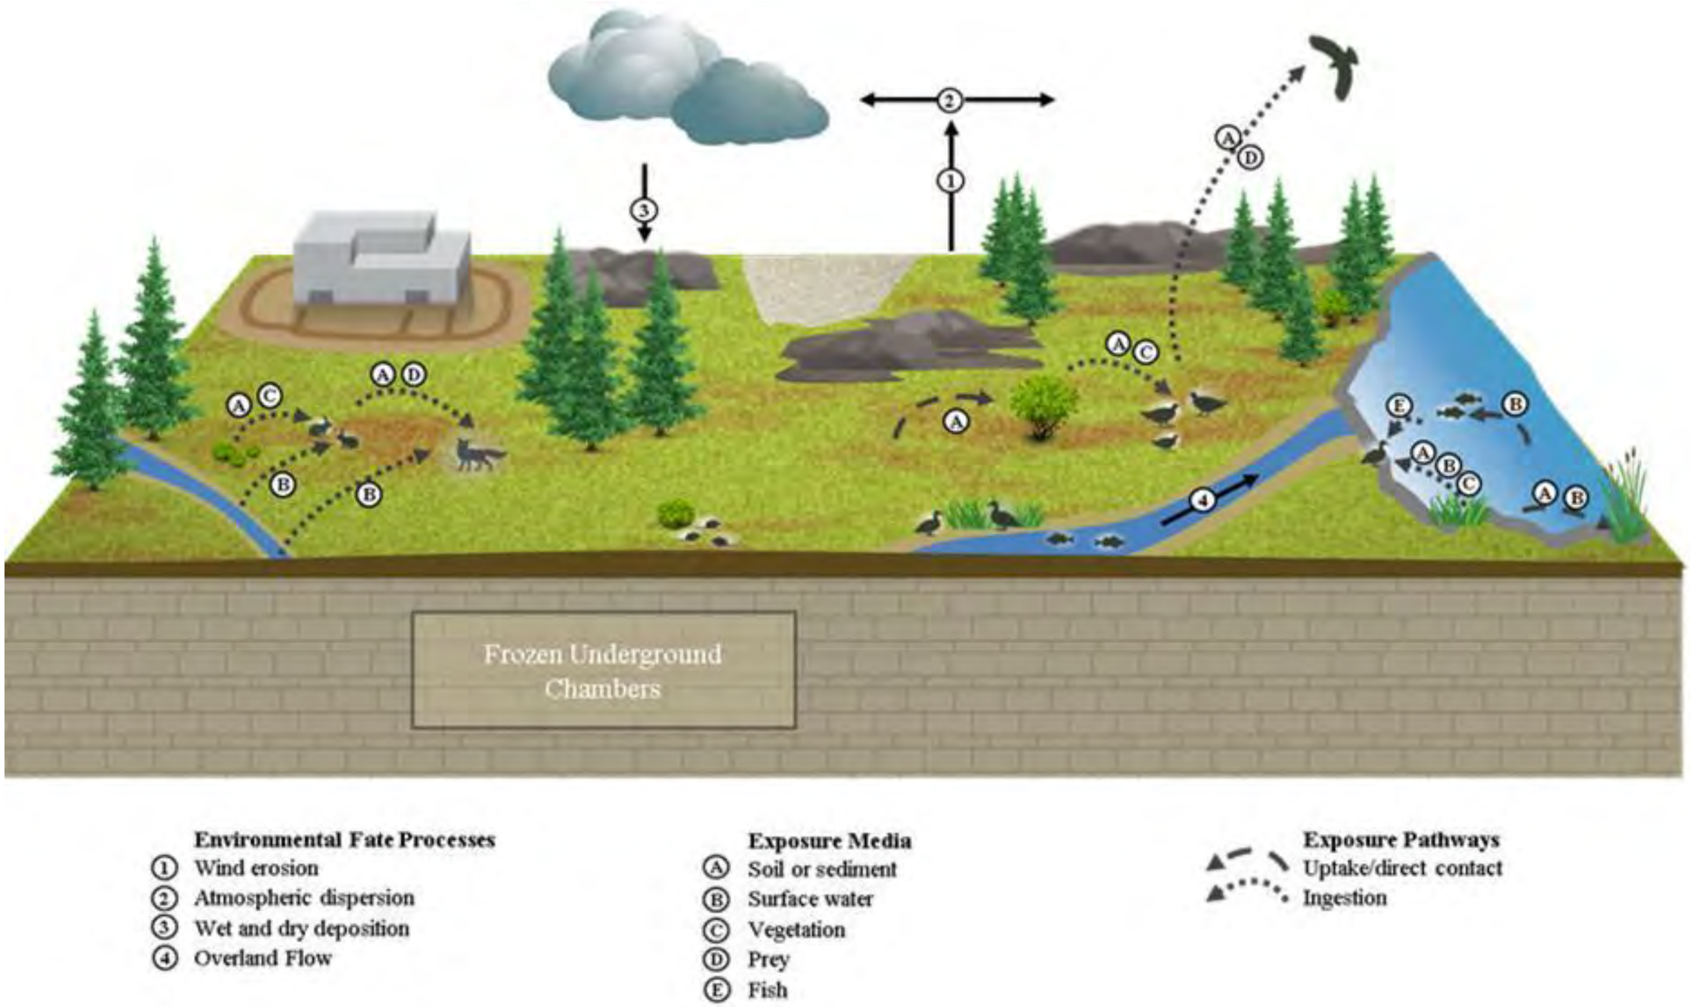
4.3.5 Assessment Endpoints and Measurement Endpoints

For this ERA, specific protection goals have not been established. The assessment focusses on assessing the risk of potential adverse effects to ecological receptors to be used in the decision-making process for the remedial actions on the Giant Mine as appropriate.

To determine the ecological significance of exposure to a COPC, ecological endpoints need to be selected. These endpoints are characteristics of an ecological component (such as fish mortality) that may be affected by exposure to a given constituent (Suter 1993; U.S. EPA 1992). There are two types of endpoints: assessment and measurement (Table 4.5). Assessment endpoints are explicit expressions of actual environmental values to be protected (U.S. EPA 1992; FCSAP 2012a). The assessment endpoints for this ERA include:

- maintenance of the health and ecological integrity of the benthic invertebrate community;
- maintenance of the health and ecological integrity of water column organisms;
- maintenance of the health and ecological integrity of the fish populations;
- maintenance of the health and ecological integrity of the wildlife that use the aquatic resources on the site;
- maintenance of the health and ecological integrity of the vegetation community on the site; and
- maintenance of the health and ecological integrity of the wildlife that use the terrestrial areas of the site.

Figure 4.9 Conceptual site model for the ecological risk assessment



Note: Schematic representation; not all pathways and receptors shown. Additional detail is provided in Appendix K. This diagram should be read in conjunction with the Site Description and other components of the Problem Formulation.

Table 4.5 Summary of assessment and measurement endpoints

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the benthic invertebrate community.	Sediment Chemistry	Sediment chemistry is compared to benchmarks (Interim Sediment Quality Guidelines [ISQG] and PELs from CCME and other benchmarks, if available).
	Benthic community*	Benthic community from exposed sites is compared to reference sites. Determination made to whether there is a difference in the taxonomic composition and relative abundances of invertebrates.
	Benthic tissue concentrations*	As a measure of the bioaccumulation, benthic invertebrate tissue data compared to data from reference locations.
	Sediment toxicity*	Whole sediment laboratory toxicity tests on representative benthic invertebrate species (14-d *Hyalella azteca* and 10-d *Chironomus sp*).
Maintenance of the health and ecological integrity of the water column organisms.	Water Chemistry	Water chemistry is compared to toxicity benchmarks are based on endpoints such as growth, survival, and/or reproduction (generally using Species Sensitivity Distributions).
	Periphyton concentrations*	As a measure of the bioaccumulation, periphyton tissue data compared to data from reference locations.
	Water toxicity*	Surface water laboratory toxicity testing on representative phytoplankton and zooplankton species (72-h *Pseudokirchneriella subcapitata*, 2-brood *Ceriodaphnia dubia*).
Maintenance of the health and ecological integrity of the fish populations.	Water Chemistry	Water chemistry is compared to toxicity benchmarks are based on endpoints such as growth, survival, and/or reproduction (generally using Species Sensitivity Distributions).
	Fish Health*	Information on fish health will be integrated in the assessment as appropriate.
	Fish Tissue	Compare measured data fish tissue data to available benchmarks specific for the protection of fish health.
Maintenance of the health and ecological integrity of wildlife that use the aquatic resources on the site.	Food chain model	Comparison of estimated exposure to COPC from the food chain to toxicity benchmarks that are based on endpoints such as growth, survival, and reproduction.
	Survey	Studies on muskrat in Baker Creek were conducted in 2003 and 2004 that looked at population density, tissue concentrations and health. These studies are considered in the risk assessment, but the contribution is limited as the information is dated.
Maintenance of the health and ecological integrity of vegetation communities on the site.	Soil Chemistry	Soil chemistry is compared to the ecological component of regulatory guidelines.
	Tissue Concentrations	Comparison of measured concentrations in vegetation to phytotoxicity benchmarks.
Maintenance of the health and ecological integrity of wildlife that use the terrestrial areas on the site.	Food chain model	Comparison of estimated exposure to COPC from the food chain to toxicity benchmarks that are based on endpoints such as growth, survival, and reproduction.
	Tissue Concentrations	Comparison of measured concentrations in tissue of small mammal (whole body) to benchmarks that are specific to tissue. There is some information available but these benchmarks are limited for the COPC considered in this assessment.

* These lines of evidence were collected for a previous investigation (Golder 2013a, 2013b) and are repeated here as no new information is available.

For determining the health and ecological integrity of receptors, consideration was given to effects at a population level. A higher level of protection is appropriate for species at risk.

Due to the difficulty in measuring direct effects on assessment endpoints, "measurement endpoints" are adopted to provide a framework for the evaluation of predicted effects. A measurement endpoint is defined as "a quantitative summary of the results of a toxicity test, a biological study, or other activity intended to reveal the effects of a substance" (Suter 1993). A measurement endpoint is a parameter that measures or describes exposure of, or an effect on, a receptor of concern (FCSAP 2012a). Different measurement endpoints were selected including:

- comparison of measured concentrations in water, sediment and soil to regulatory guidelines;
- biological surveys that summarize what biota is present and/or the health;
- laboratory toxicity testing of water and sediment collected from the site;
- comparison of measured concentrations in environmental media (e.g., fish, vegetation, mammals) to background and/or toxicity guidelines; and
- a food chain model that tracks the movement of contaminants through the environment and estimates the intake of a COPC by wildlife. These intakes were then compared to toxicity benchmarks.

4.3.6 Summary of Site Information

The ERA considered data collected at the site from 2010 to 2016. This included an extensive amount of information on abiotic components including soil, water, and sediment. A list of the reports that have been consulted is provided in Appendix A.

These reports were reviewed and a data gaps analysis carried out to determine the needs for the ERA. The data gaps that were identified related to the lack of chemistry for aquatic and terrestrial plants on the Giant Mine as well as data related to small mammals such as mice and voles.

A study was completed by Golder during the summer of 2016 to obtain information on soil, sediment, vegetation, and small mammals (co-located samples) on the Giant Mine. The program and results are provided as Attachment 1 of Appendix B. Ten co-located sediment and aquatic plant samples (sedge [*Carex aquatilis*]) were collected in lower

Baker Creek, Upper Baker Creek, and the Yellowknife area. All samples were analyzed for total metals and duplicate sediment and aquatic plant samples were collected for quality assurance (QA) purposes. For the terrestrial environment, 10 co-located soils and terrestrial plants were collected in four quadrants of the site, including four outcrop, four forest, and two wetland stations. Cranberry (*Vaccinium vitis-idaea*) and alder (*Alnus* sp.) leaves were collected to represent terrestrial forbs and shrubs. All samples were analyzed for total metals and duplicate soil and plant samples from four locations were collected for QA purposes. Plant and soil samples from five locations were also sent for arsenic bioaccessibility analysis.

Ninety-eight commercial mouse traps were set on eight transects across the Giant Mine in the fall of 2016. At all sites small mammals were trapped, and co-located soil and vegetation samples were collected. Three small mammal species were caught, including deer mouse (*Peromyscus maniculatus*), northern red-backed vole (*Myodes rutilus*), and an unidentified shrew species (*Sorex* sp.). All samples were sent for total metals analysis.

4.4 Exposure Assessment

There are many factors that go into evaluation of exposure, including receptor characteristics, receptor location, and the levels of COPC in different parts of the environment (e.g., water, soil, plants). These factors are discussed in the following sections.

The evaluation of potential effects on aquatic biota (e.g., benthic invertebrates, fish, aquatic plants) relies on water and sediment concentrations to assess direct exposure, while terrestrial plants are evaluated based on soil concentrations. For other aquatic and terrestrial receptors (i.e., mammals and birds) the exposure assessment relies on water, sediment, and soil concentrations as well as predicted concentrations for each dietary component through the food chain.

The aquatic environment was explicitly modelled to estimate future conditions; water and sediment quality predictions were made for Baker Creek and Back Bay to capture the effect of remediation activities (see Appendix K).

To facilitate evaluation of the immediate and long-term benefit of the GMRP, several different time steps were specifically identified from the overall schedule of the remedial activities, the years included current (year 2017); end of remediation (year 2030); and post remediation (years 2040, 2060, 2080, and 2120). The water and sediment quality predictions provided concentrations for all of the modelled years (see Appendix K); however, the following years were selected for discussion purposes:

Current	2017
Immediately Post-Remediation	2030
Future	2120

Similarly, future on-site soil concentrations resulting from implementation of the selected remediation measures were estimated. The predicted post-remediation soil concentrations are not expected to change substantially over time and so, for the terrestrial-based receptors, the predictions for 2030 and 2120 are the same and are grouped together and presented simply as 'future'.

4.4.1 Exposure Locations

A summary of locations for evaluation of aquatic receptors is shown in Figure 4.10, while the terrestrial receptor locations are indicated in Figure 4.11. The home range for each species was taken into account when selecting the appropriate exposure location(s) for that receptor. For example, it is appropriate to evaluate shrew on each individual quadrant of the Giant Mine, whereas, for a receptor with a larger home range, such as a fox, it is more appropriate to assume it roams over the entire Giant Mine.

Most receptors are assumed to spend their entire life on the selected exposure area; however, for a few receptors with large home ranges (e.g., falcon and lynx) it is reasonable to assume that they spend only a portion of their time at the Giant Mine with the rest spent in nearby areas which are at background conditions. For these receptors, the assumed percentage of each year spent on the Giant Mine is indicated in Figure 4.11 in brackets. For migratory birds, it is assumed that while in the area, they reside entirely on-site and are present for a sufficient time that they come into equilibrium with their surroundings; therefore, the time spent in other locations with lower concentrations is not accounted for in the assessment. A full discussion of selected receptor exposure locations is provided in Appendix J.

Figure 4.10 Exposure locations for aquatic receptors

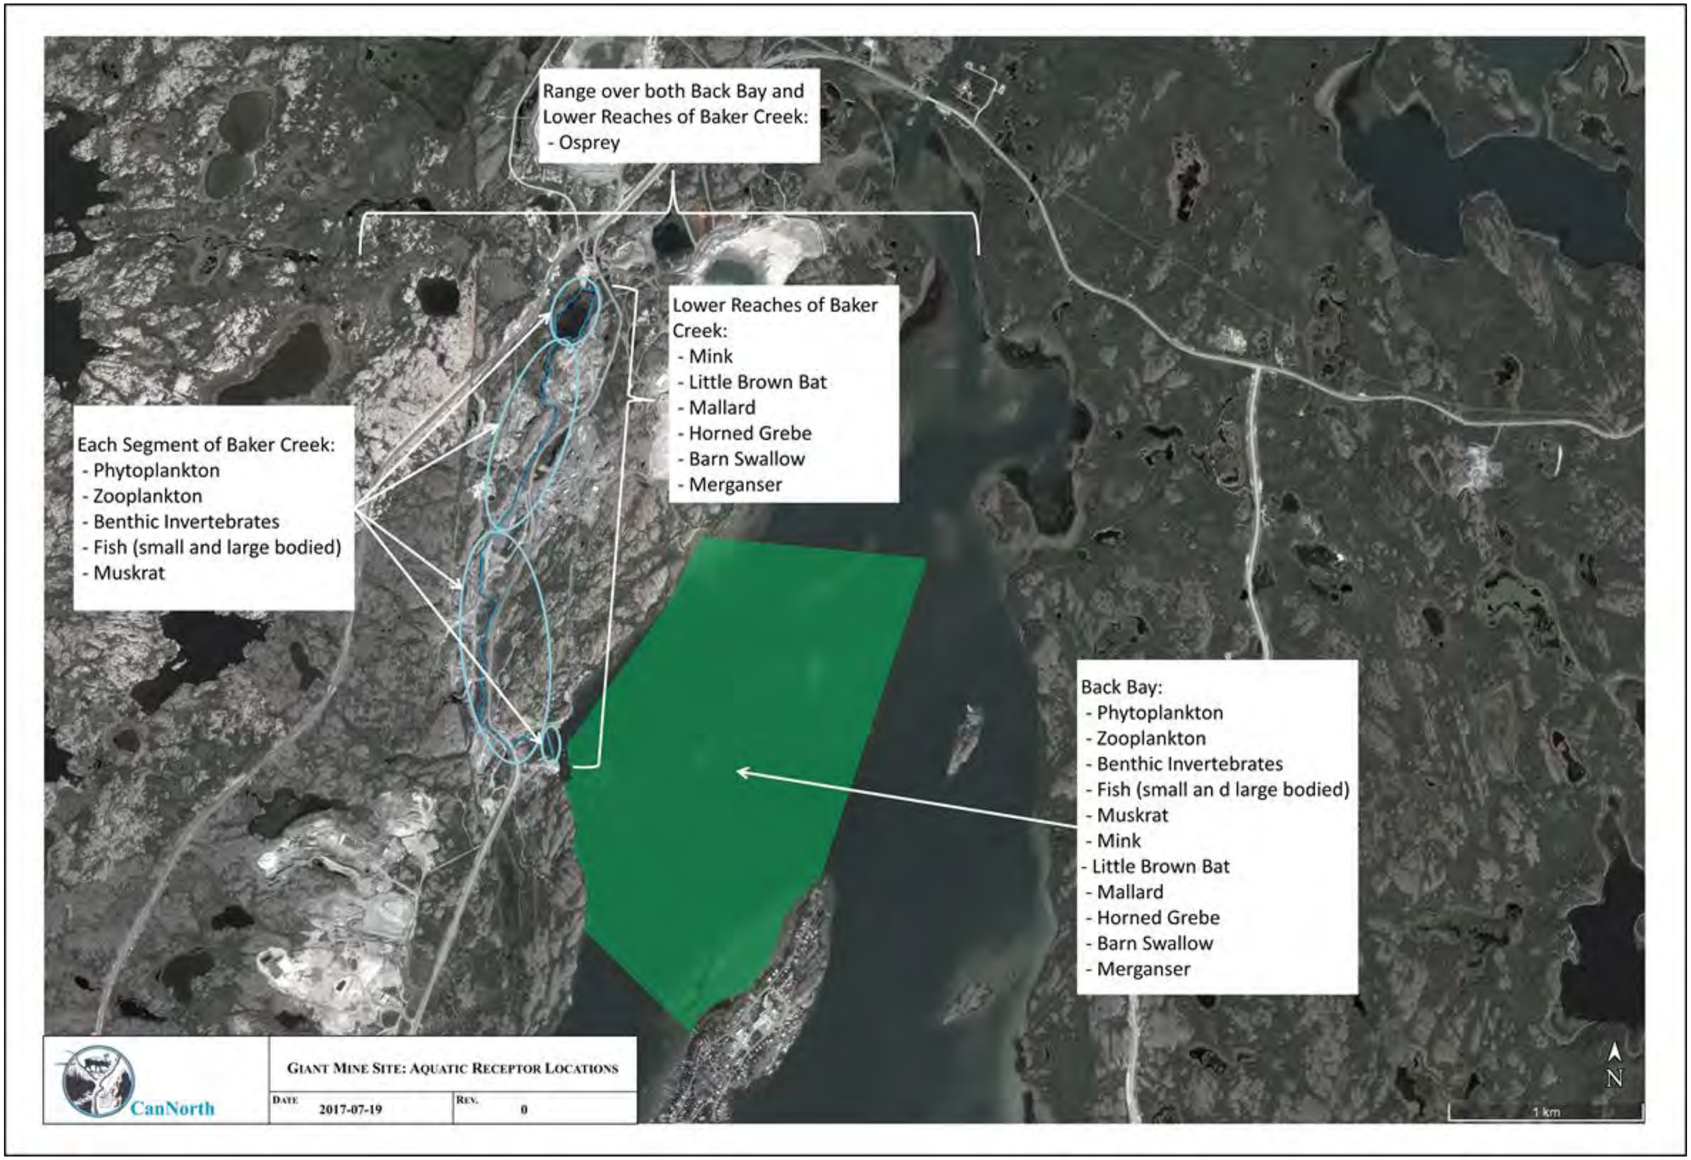


Figure 4.11 Exposure locations for terrestrial receptors

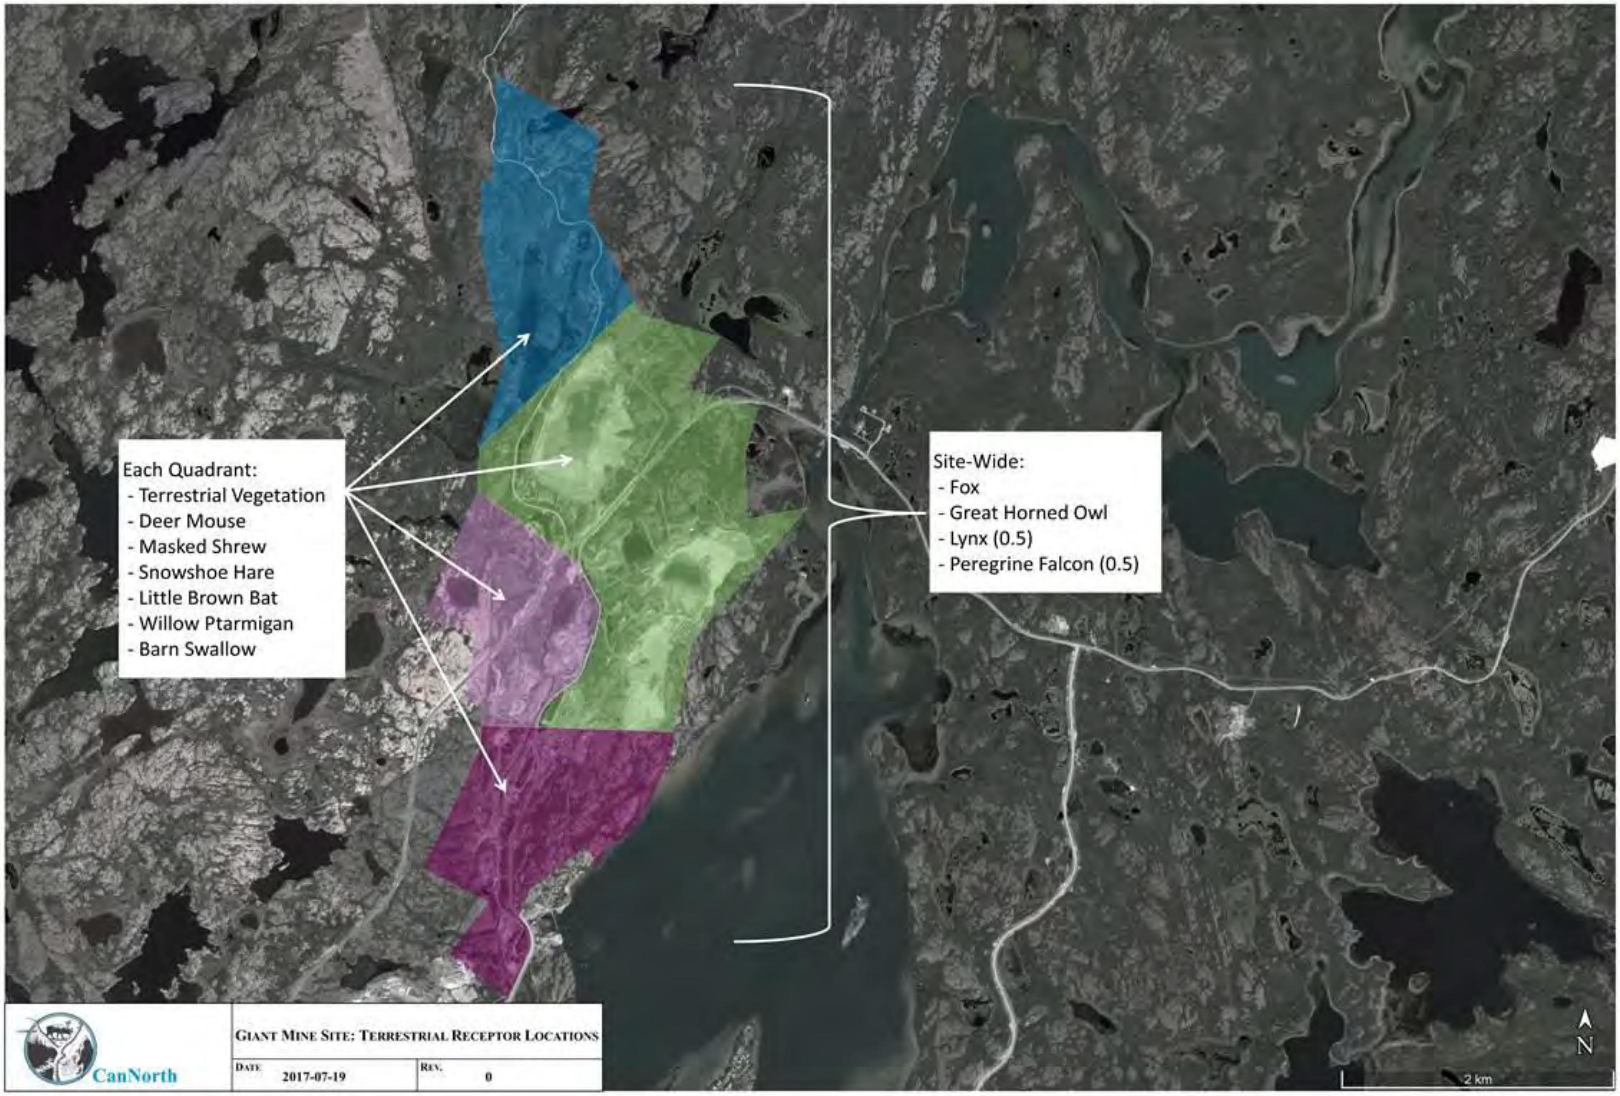


4.4.2 Exposure Point Concentrations

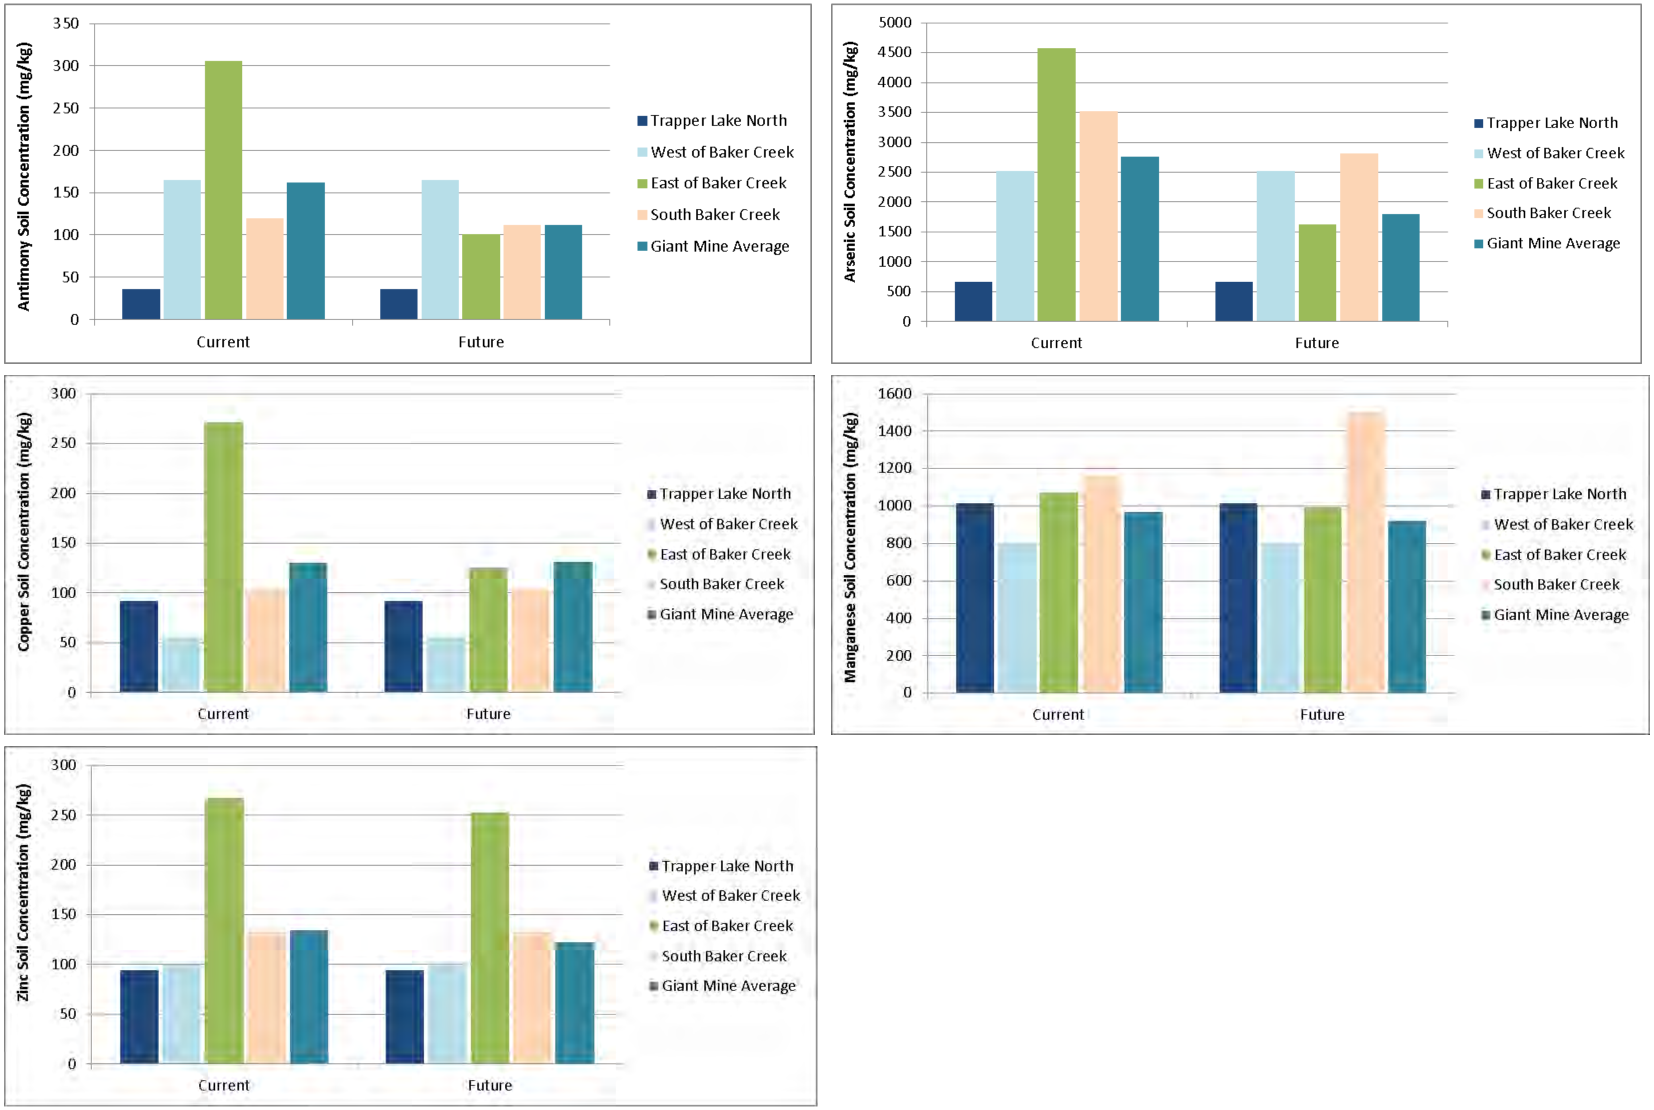
The EPCs are the concentrations of each COPC in each compartment of the environment that are used in the assessment. They are set to provide a reasonable yet cautious representation of the actual conditions in the environment that a population of receptors may experience. There is an extensive database of information that provided the basis for determining the EPCs for the ERA. However, there were some media where concentrations of COPC were estimated since measured data were not available. The setting of the EPCs is discussed in detail in subsequent sections. A full summary of all derived EPCs is provided in Appendix K.

For those combinations of receptors and COPC that were identified as a potential risk for the current scenario, the change of exposure expected as a result of the GMRP was evaluated. After the implementation of the GMRP, the concentrations in abiotic and biotic components of the environment were estimated for those COPC and receptor combinations.

4.4.2.1 Soil

The EPCs for soil taken to be representative of current conditions were derived using measured data and are summarized in Figure 4.12. Future EPCs were developed through a reanalysis of the Giant Mine data, taking into consideration the planned remediation at the site. The assumptions regarding the remediation plan were based on the results of the SDE and include covering of the tailings areas, clean up of the disturbed area soils to GNWT arsenic industrial criterion, active management of areas of extremely high arsenic around the former Mill Complex, and administrative controls. The remediation plan was discussed in Section 1.5. Soil concentrations in the four quadrants were modified based on the activities that will be undertaken in each of the quadrants. Details of the future soil concentration development are provided in Appendix K.

Figure 4.12 Soil EPCs for the Giant Mine



4.4.2.2 Surface Water and Sediment

The EPCs for surface water and sediment taken to be representative of current conditions were derived using measured data. Surface water EPCs are summarized in Figure 4.13 and Figure 4.14 for lower Baker Creek and Back Bay, respectively, while sediment EPCs are summarized in Figure 4.15 and Figure 4.16 for lower Baker Creek and Back Bay, respectively. Golder (2017) have prepared an evaluation of the loads to Baker Creek from the different areas of the Giant Mine.

The remediation plan will result in a reduction of the some of the contaminant loads to Baker Creek as there will be less contaminated runoff from the site. However, not all arsenic loads are eliminated, and there are still arsenic loads entering Baker Creek from upstream locations; these loads may be due to historical releases from the Giant Mine but will not be affected by the remediation program. Therefore, the concentrations of arsenic in Baker Creek will still be elevated in the future. As part of the remediation plan, sediment will be dredged (removed) from Reach 0 to 6 in Baker Creek; however, due to the presence of COPC in the water, the concentrations in sediment will gradually increase over time after the remediation activities have been completed. The initial conditions post-dredging are based on the information from surficial sediment in Reach 4 after re-alignment activities (Golder 2013a). Future surface water and sediment EPCs were estimated based on what is known about how contaminants currently behave. Details of the aquatic modelling are provided in Appendix K.

Figure 4.13 Surface water EPCs for lower Baker Creek segments

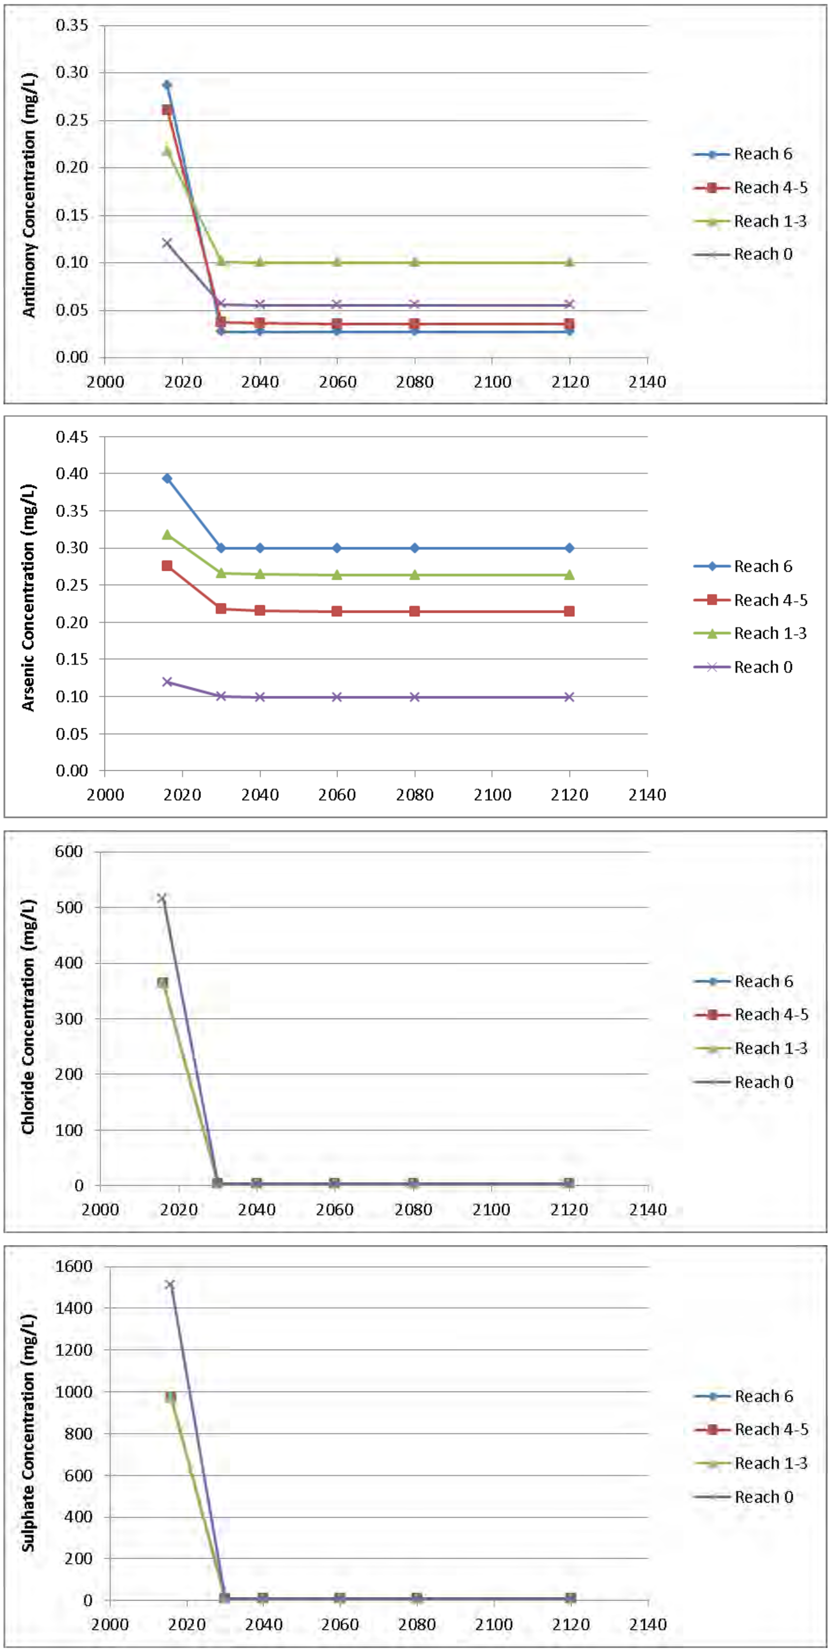


Figure 4.14 Surface water EPCs for Back Bay

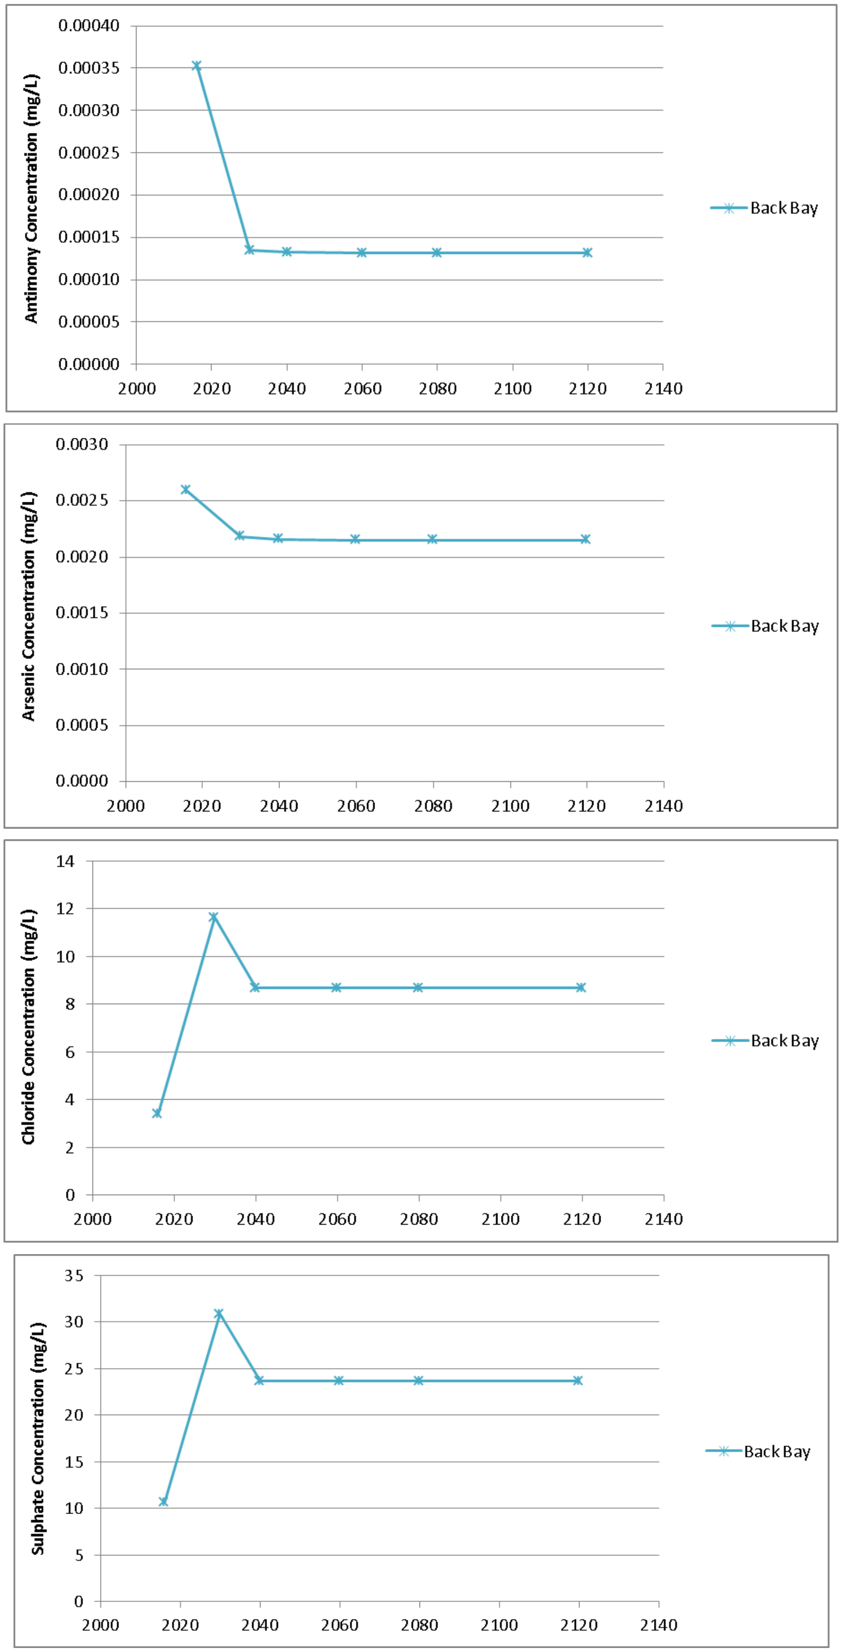

Figure 4.15 Sediment EPCs for lower Baker Creek segments

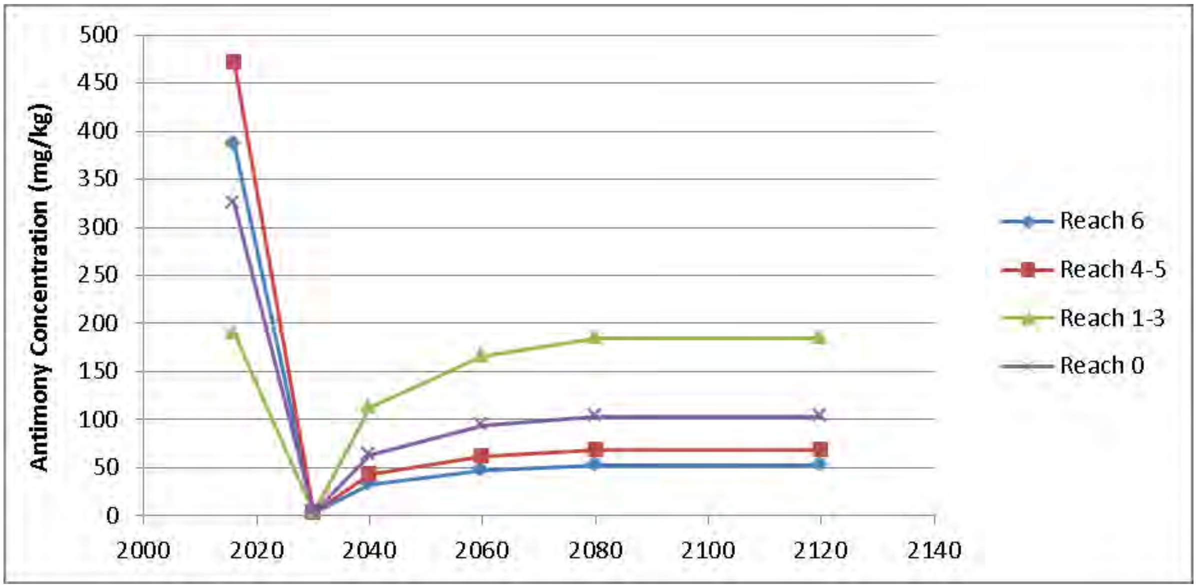

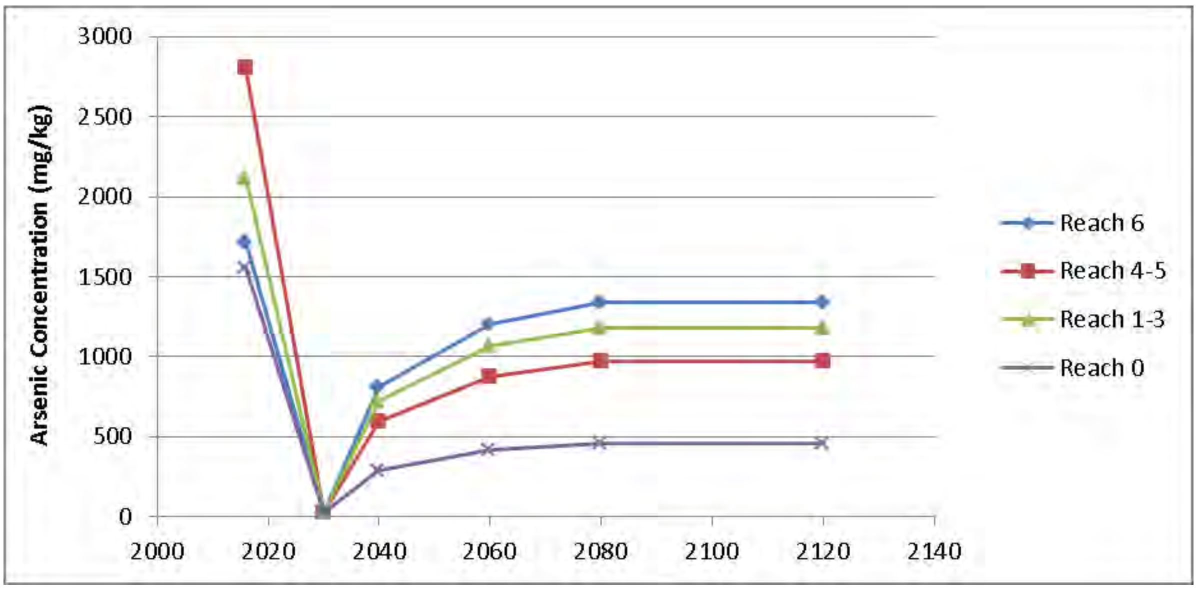

Figure 4.16 Sediment EPCs for Back Bay

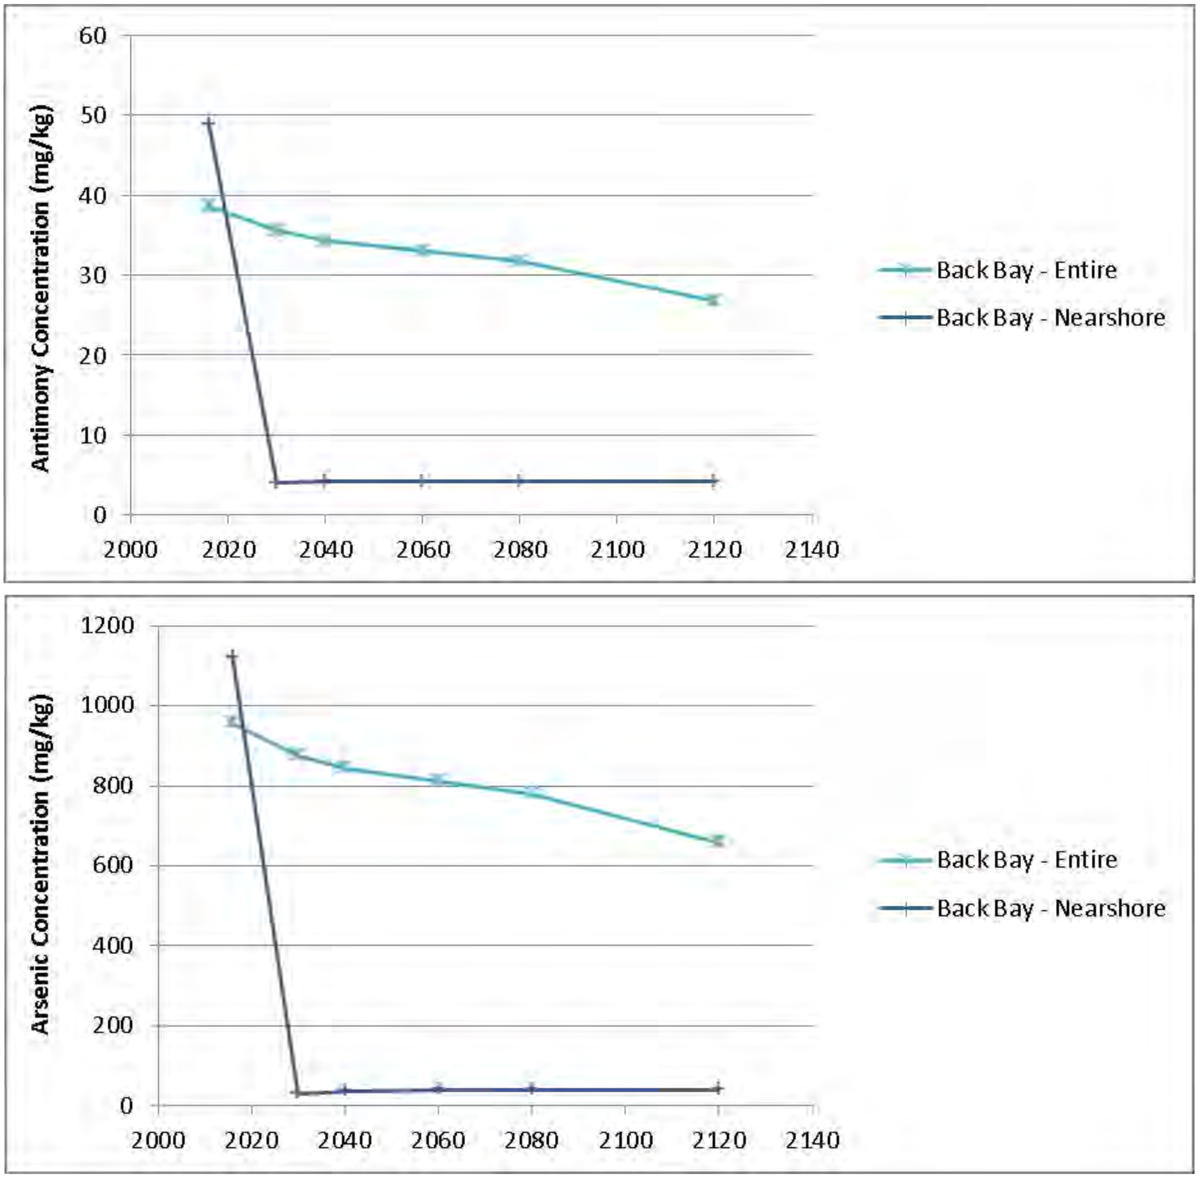

4.4.2.3 Other Media

The wildlife at the site eat a range of different food items that are found at the site. For most of these environmental compartments (e.g., aquatic vegetation, terrestrial insects, hare), current and future EPCs were estimated using either site-specific transfer factors or through the use of pathways calculations and intake estimates in conjunction with feed-to-flesh transfer factors.

Transfer factors (TFs) assume that the concentration in the biota can be estimated from the concentration in the soil, water, or sediment (as appropriate). For this assessment, site-specific TFs were developed using data collected at the Giant Mine to the extent possible. Using information from the Giant Mine allows for all of the unique characteristics of the site to be included. It is important that data are collected from similar locations (i.e., soil samples collected at the same place as plants). Figure 4.17 shows how TFs were calculated. Site-specific transfer factors were derived in this way for aquatic vegetation, benthic invertebrates, fish, terrestrial vegetation, and small mammals (shrew and mouse). While there were measured data for a number of these biotic components, data were not available for some of the locations on the Giant Mine, which resulted in the need for TFs. Details regarding derivation of the site-specific TFs are provided in Appendix K.

Figure 4.17 Derivation of site-specific transfer factors

It is also necessary to estimate concentrations of wildlife that are eaten by others (i.e., both the fox and the great horned owl eat birds such as ptarmigan). For these animals, concentrations were estimated by first approximating the intakes of the COPC and then using feed-to-flesh transfer factors obtained from literature to convert the amount ingested into a flesh concentration. These trophic transfer equations and feed-to-flesh transfer factors are provided with further discussion in Appendix K.

4.4.3 Bioavailability/Bioaccessibility Assessment and Other Considerations

Bioaccessibility refers to the portion of the total amount of a chemical that can be absorbed into the bloodstream. Once the chemical reaches the bloodstream, it can be circulated to other areas of the body where it can cause a biological effect. The amount of the chemical available to be absorbed in the blood stream depends on its chemical form.

For the ERA, it was important to examine the bioaccessibility of arsenic in particular since it was the primary chemical associated with the activities at the Giant Mine and it is present in many different chemical forms (arsenopyrite, arsenic trioxide, etc.). Some of these forms can be absorbed into the bloodstream while others cannot. In this assessment, laboratory analyses of soils, sediments, fish tissue, and plants were conducted to determine the levels of arsenic that were available for exposure.

Table 4.6 summarizes the bioaccessibility values used for arsenic in the ERA. Appendix F provides a detailed discussion on all the bioaccessibility studies for various media that have been carried out as well as an analysis of the data for use in the risk assessment. Additional information on bioaccessibility is provided in Section 3.3.4.

For COPCs and media with no information on bioaccessibility (i.e., water, benthic invertebrates, aquatic vegetation, terrestrial insects, non-foliage vegetation), no adjustment for bioavailability or bioaccessibility was made (i.e., 100% was assumed). This is a conservative assumption as it assumes that the bioavailability of the COPC in the environment is the same as used in the toxicity studies, whereas, in reality, the bioavailability of the ingested COPC is generally less than this. The values used in the assessment are provided in Appendix K.

In addition to accounting for bioaccessibility, the speciation of arsenic was taken into account in the ERA. Chemicals such as arsenic are found in different forms in the environment and the different forms do not have the same toxicity. For example, in fish there are many forms of arsenic both in an inorganic and organic form. The most common organic arsenic compound in fish, arsenobetaine, can be assumed to be non-toxic (ATSDR 2007). For this reason, it is appropriate to take into account site-specific arsenobetaine concentrations when estimating arsenic intake through fish ingestion. Additional discussion on arsenobetaine is provided in Section 3.3.4. For the ERA, the arsenobetaine content in fish was taken to be between 36 and 50% depending on location; values used are shown below in Table 4.7, and additional information is provided in Appendix K.

Table 4.6 Summary of arsenic bioaccessibility assumptions for ERA

Media	Location	Bioaccessibility Assumption	Rationale	Data Reference
Sediment	Background Locations	26%	Average of 10 samples from Townsite, assume background same as Townsite.	Golder (2016g), Table 2
	Baker Creek – Reach 7 to 11	16.6%	Average of seven samples.	Golder (2015b)
	Baker Creek – Reach 0 to 6	44%	Single sample from Reach 6.	Golder (2015b)
	Back Bay	26%	Average of 10 samples from the Townsite area.	Golder (2016g), Table 2
	Baker Creek/Back Bay Combined	35%	Average of Back Bay and Baker Creek Reach 0 to 6.	-
Fish	Background Locations	62%	Average of lake whitefish, northern pike, and inconnu from background locations.	Stantec (2014d), Appendix C
	Baker Creek – Reach 7 to 11	62%	Assumed same as background.	Stantec (2014d), Appendix C
	Baker Creek – Reach 0 to 6	61%	Average of lake whitefish and northern pike from the outlet of Baker Creek.	Stantec (2014d), Appendix C
	Back Bay	68%	Average of lake whitefish and northern pike from Back Bay.	Stantec (2014d), Appendix C
	Baker Creek/Back Bay Combined	65%	Average of Back Bay and Baker Creek Reach 0 to 6.	-
Waterfowl	Background Locations	50%	Average of hare muscle from uncontaminated areas.	Koch et al. (2013)
	Back Bay	38%	Average of eight hare samples from contaminated areas.	Koch et al. (2013)
	Baker Creek/Back Bay Combined	38%	Average of Back Bay and Baker Creek Reach 0 to 6.	-
	Baker Creek – Reach 0 to 6	38%	Average of eight hare samples from contaminated areas.	Koch et al. (2013)
Soil	Background Locations	38%	Average of nine samples representative of undisturbed soils.	Golder (2016j)
	Giant Site	36%	Average of 38 samples from disturbed areas.	Golder (2016c)
	Giant Townsite	30%	Average of eight samples from the Townsite area.	Golder (2016g), Table 4
Foliage	All	34%	Average of 10 alder and cranberry leaf samples.	Golder (2016g), Table 8
Mouse/Shrew/ Hare/Ptarmigan	Background Locations	50%	Average of hare muscle from uncontaminated areas.	Koch et al. (2013)
Mouse/Shrew/ Hare/Ptarmigan	Giant Site and Townsite	38%	Average of eight hare samples from contaminated areas.	Koch et al. (2013)
Moose/Caribou	All	50%	Average of hare muscle from uncontaminated areas.	Koch et al. (2013)

Table 4.7 Summary of fish arsenobetaine assumptions for ERA

Location	Arsenobetaine Content	Rationale	Data Reference
Background Locations	36%	Average of lake whitefish, northern pike, and inconnu from background locations.	Stantec (2014d), Appendix C
Baker Creek – Reach 7 to 11	36%	Assumed same as background.	Stantec (2014d), Appendix C
Baker Creek – Reach 0 to 6	46%	Average of lake whitefish and northern pike from the outlet of Baker Creek.	Stantec (2014d), Appendix C

4.4.4 Receptor Characterization

Aquatic and terrestrial receptors chosen for the current assessment were selected to represent a wide range of potential exposures. Receptor characteristics for wildlife selected (as outlined in Section 4.3.3) are provided in Appendix J. These characteristics include the typical body weight, the types of food receptors eat (diet), and how much food and water they would consume in a day. Where available, receptor characteristics from module 3 of the FCSAP guidance (FCSAP 2012b) were adopted for the assessment.

4.4.5 Exposure Estimation

The exposure estimation uses the EPCs in environmental media and the receptor characteristics to estimate the total intake of the COPC by the selected aquatic and ecological receptors. This is illustrated in Figure 4.18 where it shows that the total intake by a muskrat includes the amount of water, aquatic vegetation, and sediment that is consumed. Exposures due to ingestion of each dietary component, as well as water and soil or sediment, were calculated using equations provided in Appendix K. Where appropriate, background exposures were taken into account in the exposure estimates.

Figure 4.18 Estimating intakes by wildlife

For aquatic biota, intakes of arsenic and antimony were estimated using the exposure assumptions outlined above. Figure 4.19 presents a summary of the estimated current arsenic intakes for a subset of the receptors in the aquatic environment. This figure illustrates that benthic invertebrates and emergent aquatic insects are a driving factor for exposure in many receptors, while intake of soil is also a large component of intakes for the bat and swallow. Figure 4.20 presents a similar summary for a subset of the terrestrial receptors. As can be seen, this figure shows that a large portion of arsenic intake for all receptors is due to soil ingestion. The bat and swallow are assumed to ingest soil due to where they live and roost/nest; however, they were evaluated for both an aquatic diet (eating emergent aquatic insects like mosquitos) and a terrestrial diet (eating insects such as beetles). These figures provide only a summary of some of the results, estimated intakes for all receptors, locations, and COPC are provided in Appendix M.

For less complex receptors such as aquatic biota (e.g., benthic invertebrates, fish, aquatic plants) and terrestrial plants, potential effects are not based on intakes but instead are based on comparison of water, sediment, or soil concentrations to benchmarks or comparison of tissue concentrations to benchmarks, where available.

Figure 4.19 Estimated current arsenic intakes for wildlife in the aquatic environment

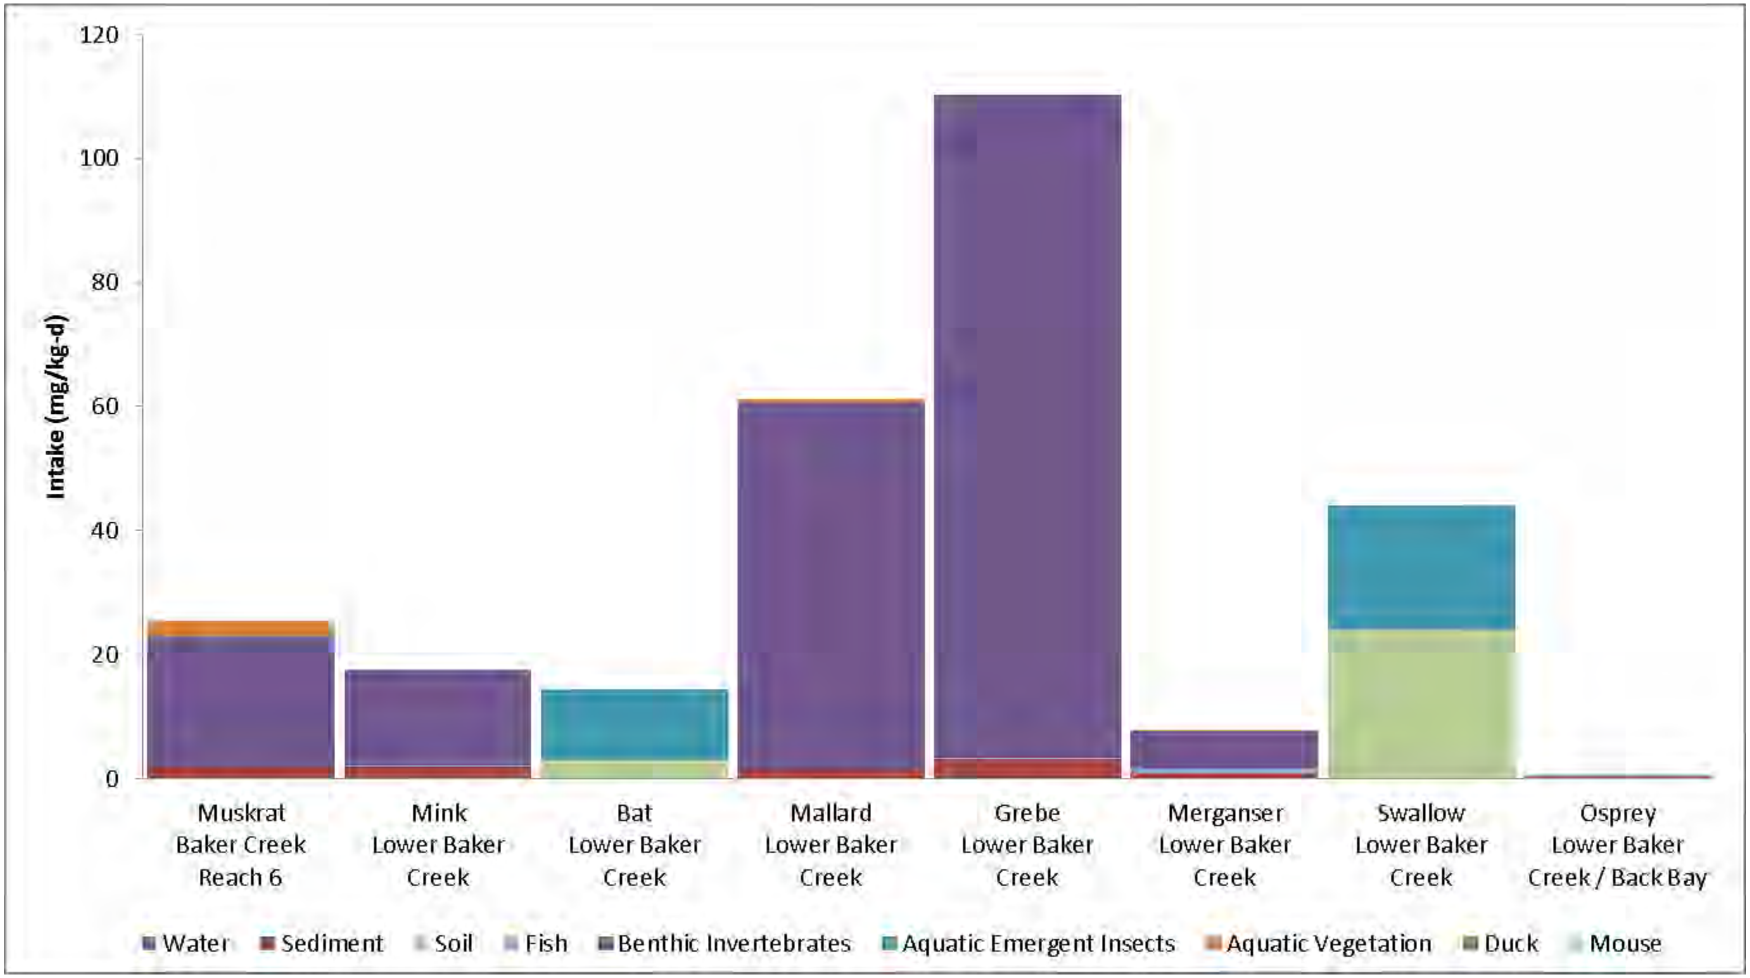

Figure 4.20 Estimated current arsenic intakes for wildlife in the terrestrial environment

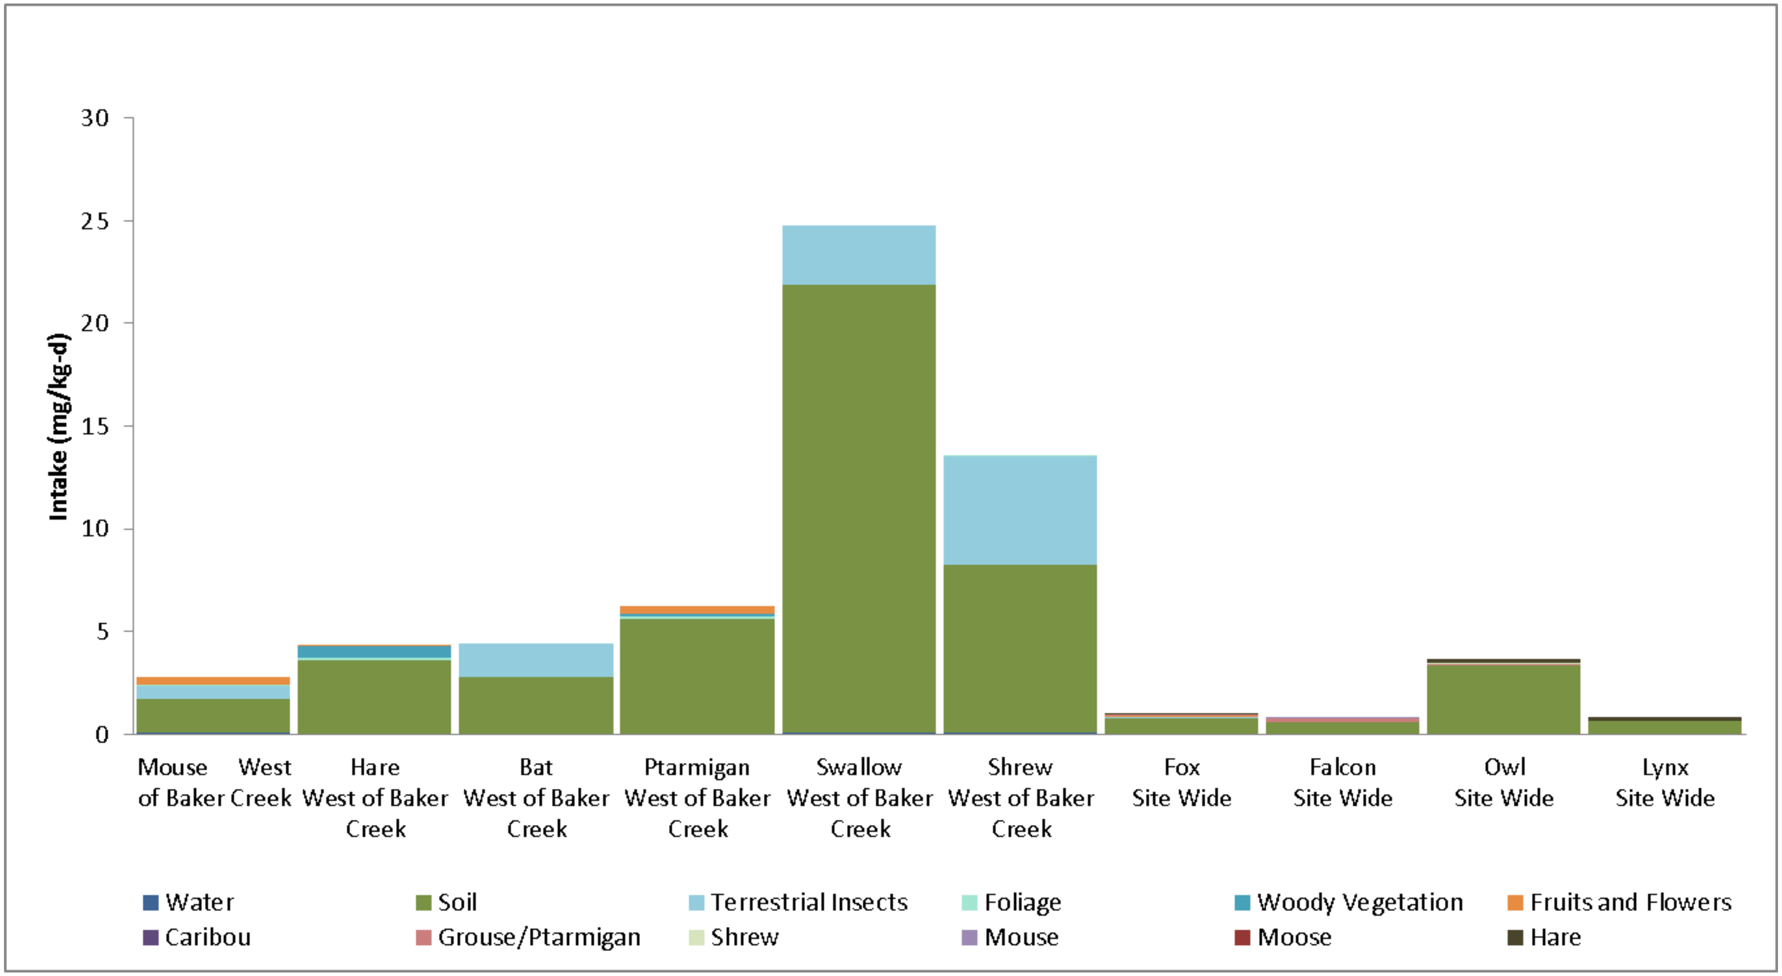

4.5 Effects Assessment

4.5.1 Observed Effects (Direct Contact Pathways)

Where available, findings from studies investigating ecological community health in the Giant Mine area were examined and incorporated in the ERA as lines of evidence. These are primarily studies that were discussed as part of a previous investigation (Golder 2013a) and are largely focused on the aquatic environment surrounding the Giant Mine. Observational studies with information either about community health or comparisons to reference areas that were incorporated in the ERA include:

- benthic community observations versus reference locations;
- fish health information; and
- muskrat population density and health.

These are discussed as lines of evidence in the risk characterization (Section 4.6.1).

4.5.2 Site-Specific Thresholds (Direct Contact Pathways)

4.5.2.1 Species Sensitivity Distribution Development

Potential effects to aquatic biota (e.g., zooplankton, aquatic plants, fish) were evaluated using derived Species Sensitivity Distributions (SSDs). This approach involves reviewing aquatic biota toxicity data from reputable sources for appropriateness at this site (e.g., include information for freshwater species only) and then using the resulting dataset to statistically fit a curve, which is a representation of the toxicity of a specific COPC, to aquatic biota. This SSD approach is used by the CCME in the development of generic water quality guidelines. Thus, this approach has been adopted for the development of aquatic toxicity thresholds used in the ERA and is, therefore, supported by the CCME protocol (CCME 2007).

SSD curves were developed for antimony, arsenic, chloride, and sulphate and are presented below. As sulphate toxicity has been found to be dependent on the hardness of the water, SSD curves were developed for sulphate to span different ranges of hardness. Full details regarding the development of these curves as well as the full datasets are provided in Appendix L.

Figure 4.21 Antimony SSD for aquatic toxicity

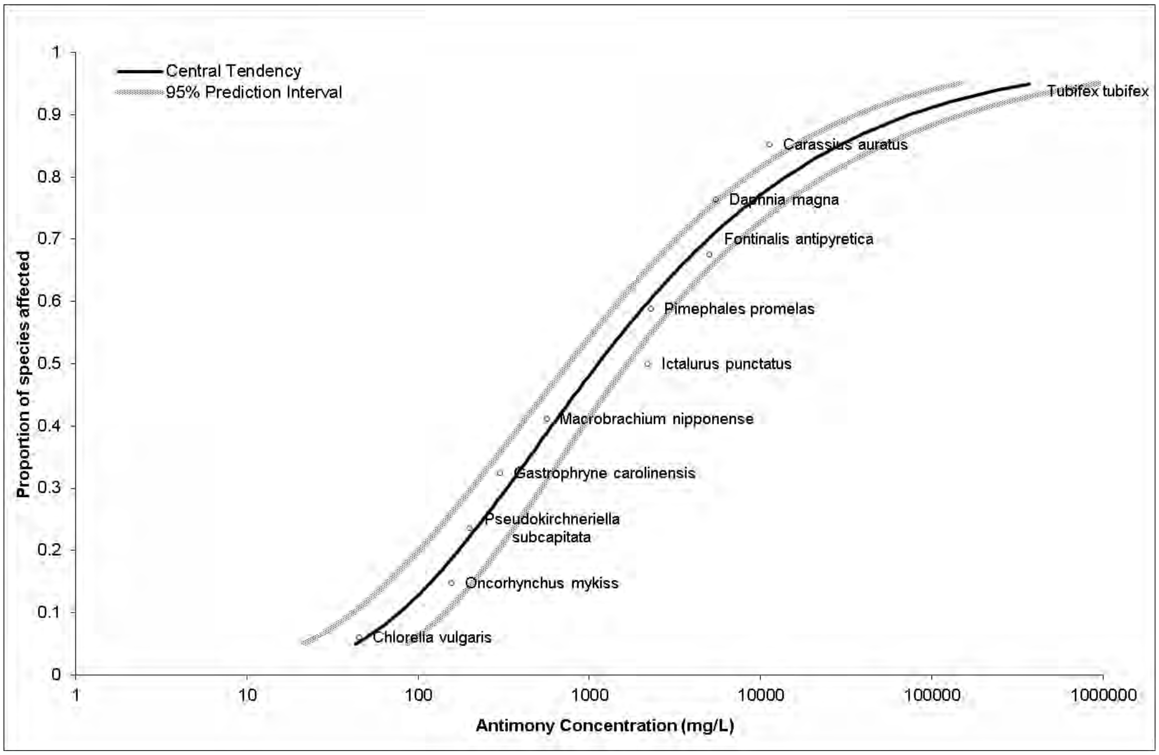

Figure 4.22 Arsenic SSD for aquatic toxicity

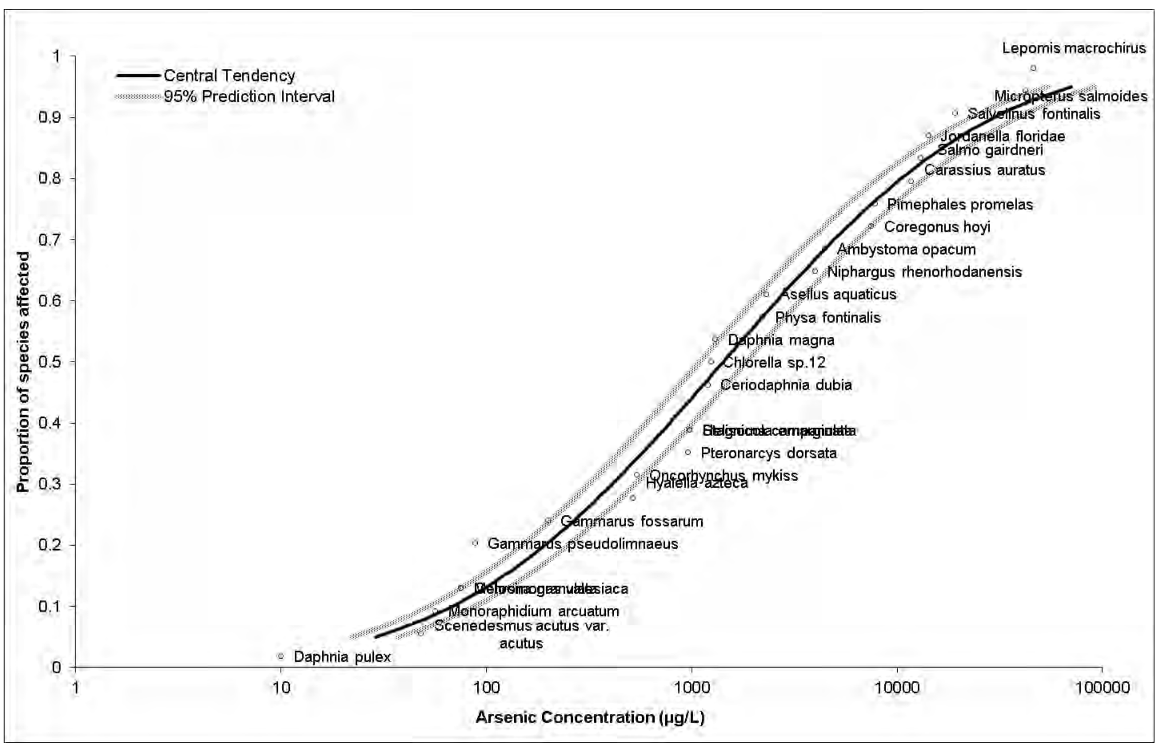

Figure 4.23 Chloride SSD for aquatic toxicity

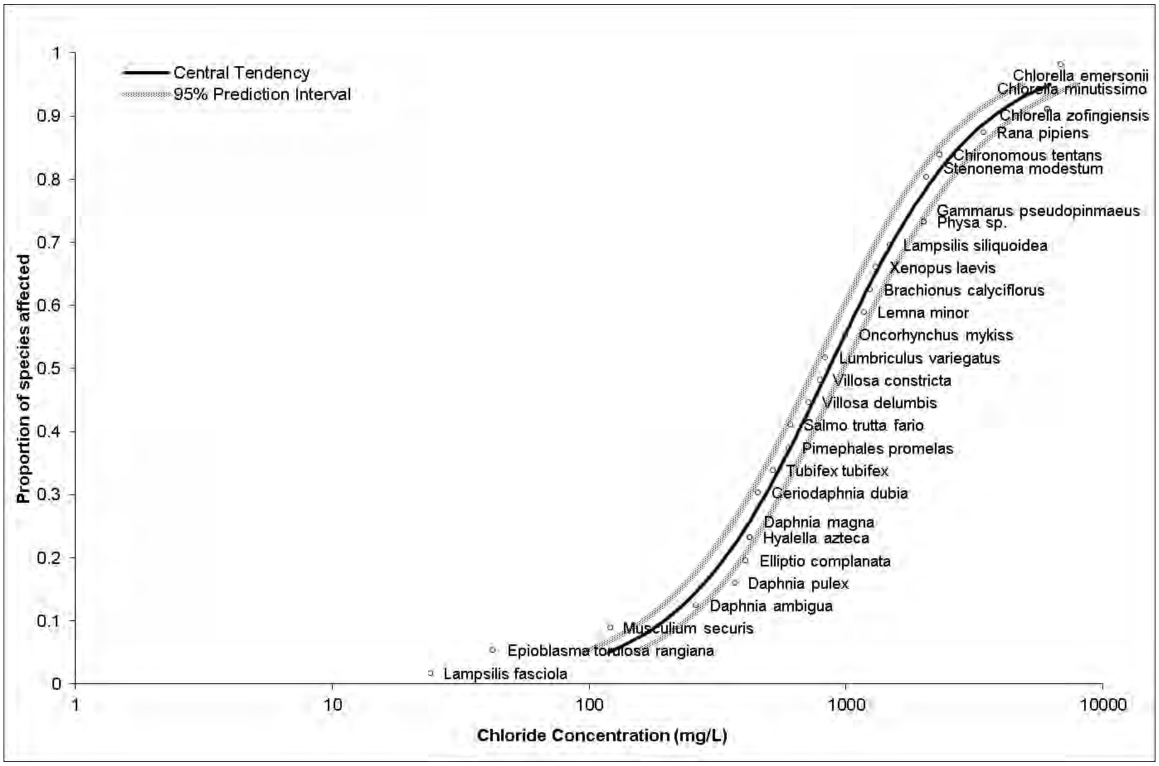

Figure 4.24 Sulphate SSD for aquatic toxicity

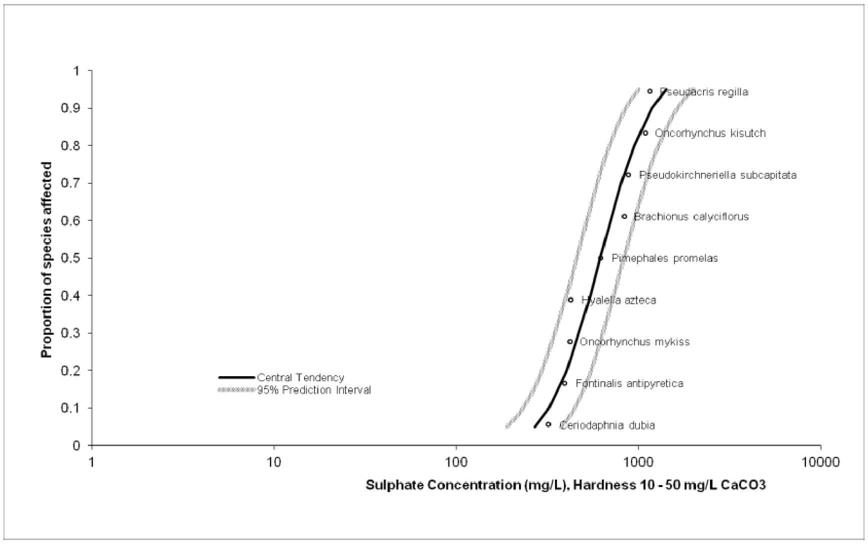

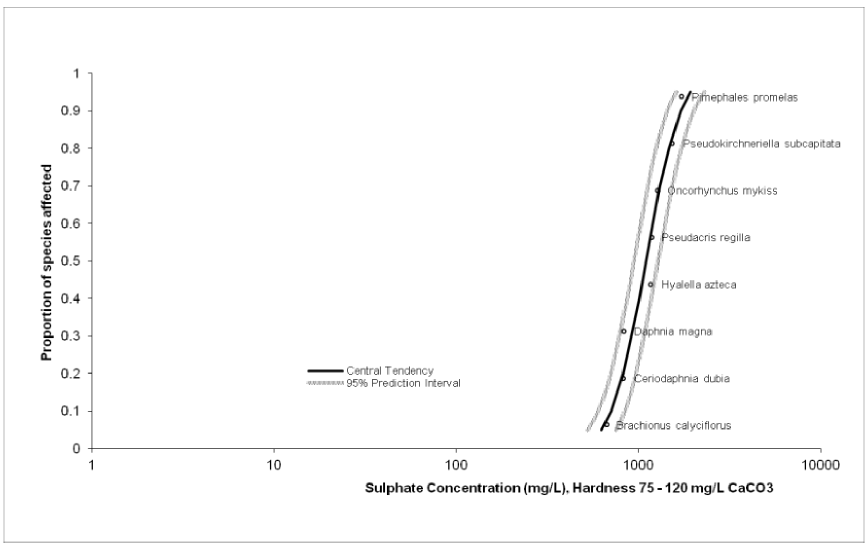

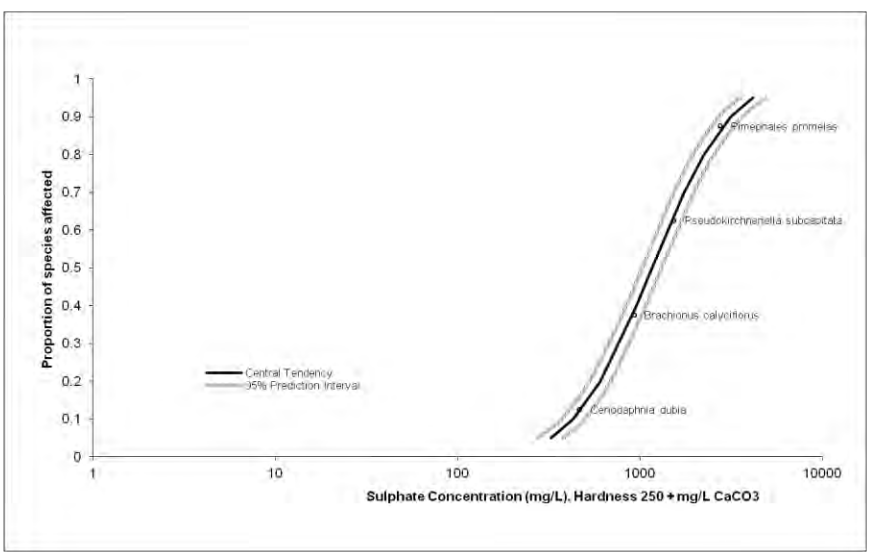

4.5.2.2 Site-Specific Toxicity Testing

As part of a previous study conducted by Golder (2013a), acute and chronic toxicity tests were performed on four water samples: three from Baker Creek and one from the Yellowknife River reference location. The tests included:

- acute toxicity with juvenile Rainbow trout (*Oncorhynchus mykiss*) according to Method EPS 1/RM/13 (EC 2000a). The test duration of 96h and survival was the endpoint measured (96-h LC50);
- acute toxicity with water flea (*Daphnia magna*) according to Method EPS 1/RM/14 (EC 2000b). The test duration of 48 h and survival was the endpoint measured (48-h LC50);
- chronic toxicity with water flea (*Ceriodaphnia dubia*) according to Method EPS 1/RM/21 (EC 2007a). The test duration was approximately 7 days and survival and reproduction were the endpoints measured (LC25, LC50, IC25, IC50); and
- chronic toxicity with an algae (*Pseudokirchneriella subcapitata*) according to Method EPS 1/RM/25 (EC 2007b). The test duration was approximately 72 hours and growth inhibition was the endpoint measured (IC25, IC50).

In addition, Golder (2013a) collected sediment sampling for toxicity testing included the following:

- 14 day toxicity with crustacean *Hyalella azteca* according to EPS 1/RM/33 (EC 1997a) methods. Survival and growth were the endpoints measured.
- 10 day toxicity with midge *Chironomus tentans* according to EPS 1/RM/32 (EC 1997b) methods. Survival and growth were the endpoints measured.

The results for each sediment from the exposure station was compared to the average response from the Yellowknife River reference station to determine whether <20% or >50% adverse effects were observed per the FCSAP aquatic sites framework (Golder 2013a).

A full discussion of the sample handing, results, and QA are presented in by Golder (2013a). The results of the toxicity test are summarized as one of the lines of evidence in the risk characterization section.

4.5.3 Toxicity Reference Values for Plants and Wildlife

Toxicity reference values (TRVs) are defined as an exposure concentration or dose for a COPC that is not expected to cause an unacceptable level of effect in a receptor.

4.5.3.1 Dose-Based TRVs for Wildlife

The TRVs selected for comparison to the intake calculated for wildlife are presented in Table 4.8, while the selection of these values is detailed in Appendix L. When available, the values were selected from Environment Canada's FCSAP guidance (FCSAP 2015b) and were otherwise derived in a similar manner for COPC not included in the FCSAP guidance. Environment Canada generally selected values from the U.S. EPA Eco-SSL documents or from Quebec documents (CEAEQ). It should be noted that the FCSAP guidance document is a draft report and the TRVs were provided by ECCC for use on this project; this information should not be used on a wider basis until the guidance document has been finalized. The TRVs were derived from toxicological endpoints of survival, growth, and reproduction.

Table 4.8 Summary of default wildlife toxicity reference values

COPC	Mammals			Birds		
	TRV (mg/kg-d)	Endpoint	Source	TRV (mg/kg-d)	Endpoint	Source
Antimony	0.059	Reproduction	Eco-SSL (U.S. EPA 2005a)	No data		
Arsenic [a]	1.04	Growth	Eco-SSL (U.S. EPA 2005b)	4.4	Growth	CEAEQ (2012)
Copper [a]	5.6	Growth and survival	Eco-SSL (U.S. EPA 2007a)	4.5	Reproduction	CEAEQ (2012)
Manganese	51.5	Growth and Reproduction	Eco-SSL (U.S. EPA 2007b)	179	Growth and Reproduction	Eco-SSL (U.S. EPA 2007b)
Zinc [a]	75.4	Growth and reproduction	Eco-SSL (U.S. EPA 2007c)	66.1	Growth and reproduction	Eco-SSL (U.S. EPA 2007c)

Source: a – EC (2015b) Module 7 – Default wildlife Toxicity Reference Values (TRVs).

4.5.3.2 Tissue Benchmarks for Wildlife and Plants

In addition to selected dose-based TRVs, tissue benchmarks derived specifically as indicators of either no or lowest effects levels were also used, as available, with measured data from the Giant Mine to evaluate population health of a number of species. This approach was taken for fish, small mammals, and terrestrial plant foliage. Available benchmarks for these media are presented in this section; further discussion regarding sources of these values is presented in Appendix L.

Table 4.9 Tissue benchmarks selected for evaluation of fish

COPC	NOEC	LOEC
	mg/kg ww	
Antimony	5	9
Arsenic	1.5	2

Notes: NOEC – No Observed Effects Concentration; LOEC – Lowest Observed Effects Concentration.
Benchmarks apply to whole fish and were obtained from CH2MHill (2015).

Table 4.10 Terrestrial plant phytotoxic levels

COPC	Phytotoxic Leaf Concentration [a] mg/kg dw
Antimony	150
Arsenic	3-26
Copper	20-100
Manganese	40-1,000
Zinc	100-1,500

Notes: Ranges based on Davis et al. (1978), McBride (1994), Langmuir et al. (2004), and Kabata-Pendias (2011).

Table 4.11 Tissue benchmarks selected for evaluation of small terrestrial mammals

COPC	Toxic Tissue Concentration mg/kg ww
Arsenic	6 - 28 liver 5 - 26 kidney
Copper	690 liver 23 kidney

Notes: Information was not available for antimony, manganese or zinc.
Source: Puls (1994).

4.6 Risk Characterization

Risk characterization is the process of estimating the potential for an adverse effect on populations of ecological receptors based on the information obtained from the exposure and effects assessments. The risk characterization for the ERA is discussed in the following sections; more detailed results are provided in Appendix M.

The risk characterization uses the extensive data collected from the Giant Mine on soil, water, and sediment, as well as other information, relying mostly on recently collected information but also considering older information where appropriate. The strengths and weaknesses of the different sources of information used in the ERA are discussed.

4.6.1 Weight of Evidence Evaluation

The WOE approach taken in characterizing potential risks within the ERA involved drawing from all available information. For each of the assessment endpoints (e.g., benthic invertebrates, fish, terrestrial wildlife), the available Lines of Evidence (LOE) were evaluated and considered together, including information on the strengths and weaknesses of the various pieces of information in order to form a conclusion on the potential impact.

The assessment of potential effects on aquatic biota is discussed in Section 4.6.1.1; the information in this section was used as a LOE to support the assessment of the selected populations of aquatic biota (Sections 4.6.1.3 and 4.6.1.4). The assessment endpoints in the terrestrial environment are discussed in Sections 4.6.1.6 and 4.6.1.7.

4.6.1.1 Aquatic Biota

The assessment of potential effects on aquatic biota involved the development of SSDs for antimony, arsenic, chloride, and sulphate. These SSD curves integrate toxicity information, obtained from a review of the scientific literature, on a range of aquatic biota and are used to support the assessment of different communities. The SSD curves are presented in this section and referenced as a LOE where appropriate.

The complete comparison of current and predicted water quality to the derived SSD curves is presented in Appendix M; a few examples are presented here for illustration.

In general, it is expected that average conditions across Back Bay (both current and future) pose low risk to aquatic biota. This is illustrated in Figure 4.25 where the surface water EPCs developed for Back Bay are well below the SSD-derived 95% protection level. Similar trends are seen for antimony, chloride, and sulphate.

This is not the case, however, for surface water levels in lower Baker Creek; the following examples are provided for a sub-set of the Baker Creek segments.

Current chloride and sulphate concentrations in all segments of lower Baker Creek are predicted to be above levels protective of 80% of species due to the discharge from the effluent treatment plant; however, in the future, chloride and sulphate concentrations in lower Baker Creek are predicted to drop well below the 95% protection level (see Figure 4.26 for chloride in Baker Creek Reach 0). This is due to the fact that the discharge from the effluent treatment plant will be relocated to the mouth of Baker Creek.

For antimony, current conditions in Reach 1-3, Reach 4-5, and in Baker Pond (Reach 6) are all above the 80% protection level concentration and levels in Reach 0 are above the 90% protection level. This means that there is a potential for 10 to 20% of aquatic species present to be affected. While antimony levels are expected to fall in the future, concentrations in Reach 1-3 are expected to remain above the 90% protection level and levels in Reach 0 are expected to remain above the 95% protection level. This is shown in Figure 4.27 for antimony in Baker Creek Reach 1-3.

Figure 4.25 SSD curve for current and future conditions – arsenic in Back Bay

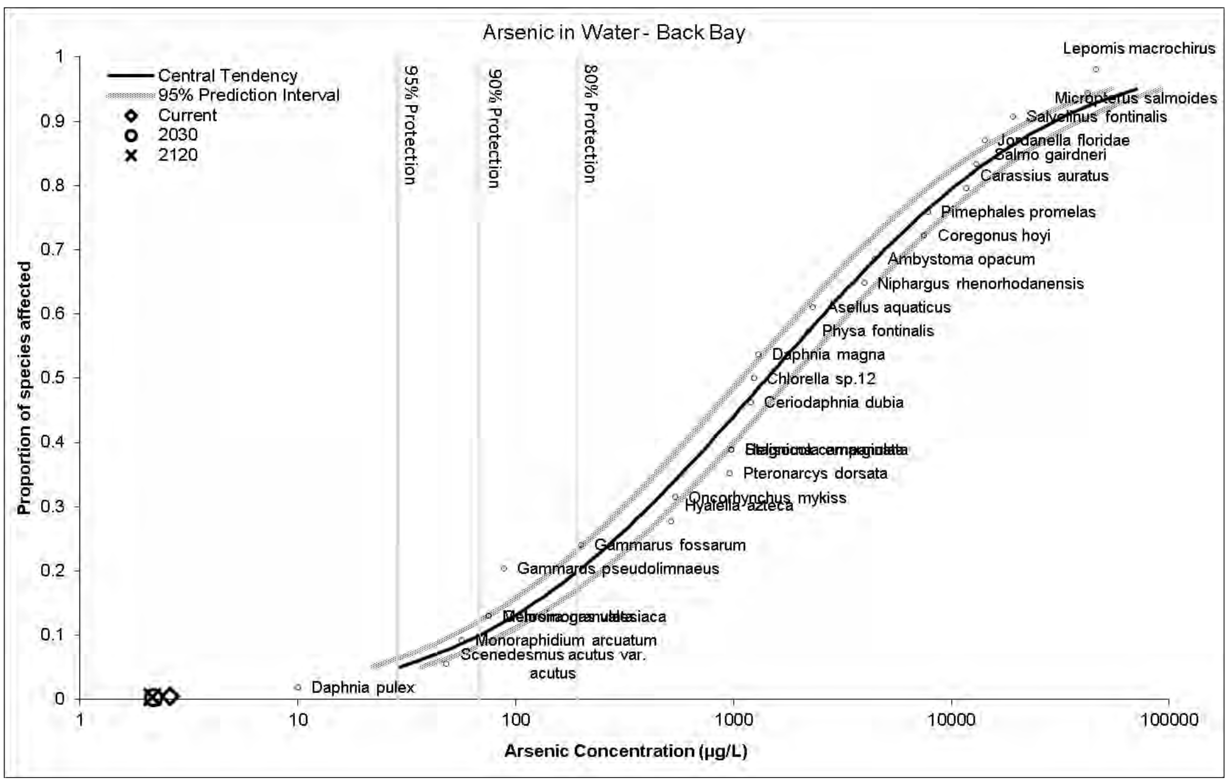

Figure 4.26 SSD curve for current and future conditions – chloride in Baker Creek Reach 0

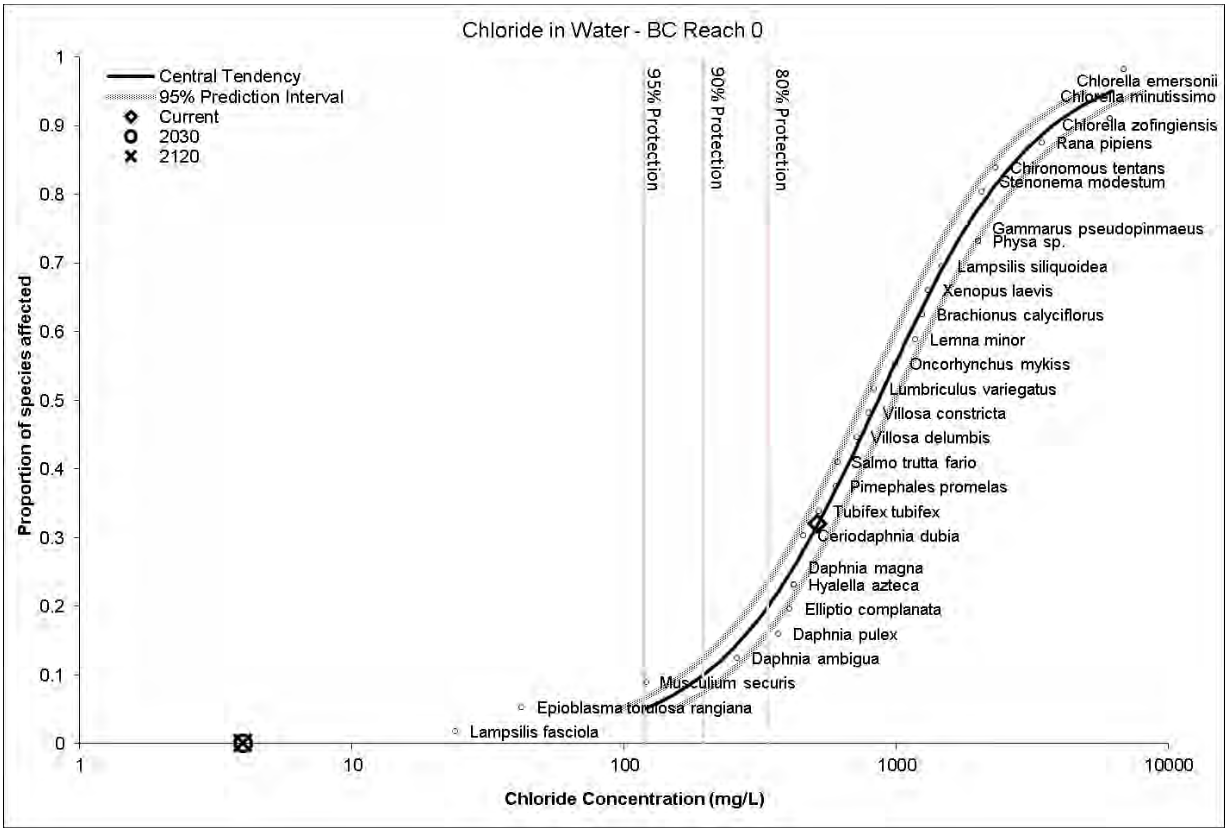

Figure 4.27 SSD curve for current and future conditions – antimony in Baker Creek Reach 1-3

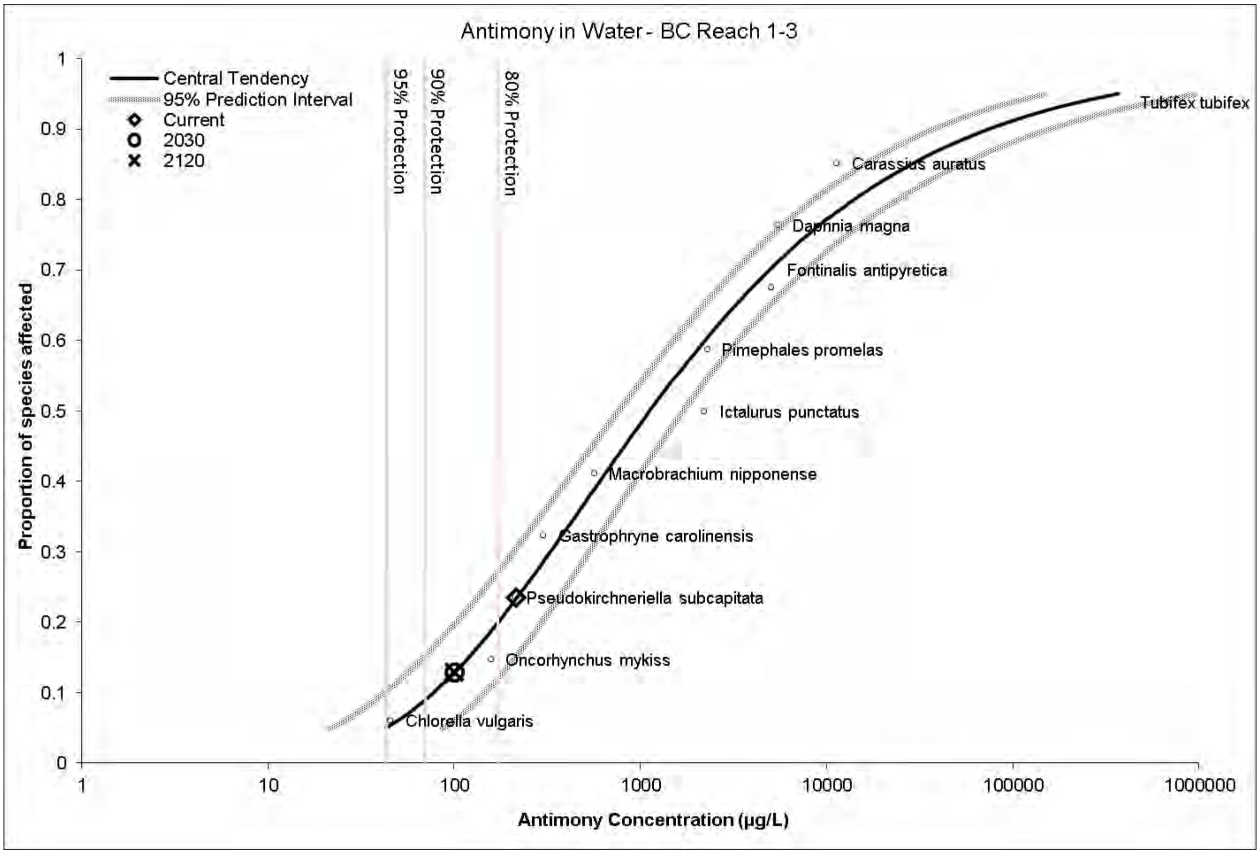
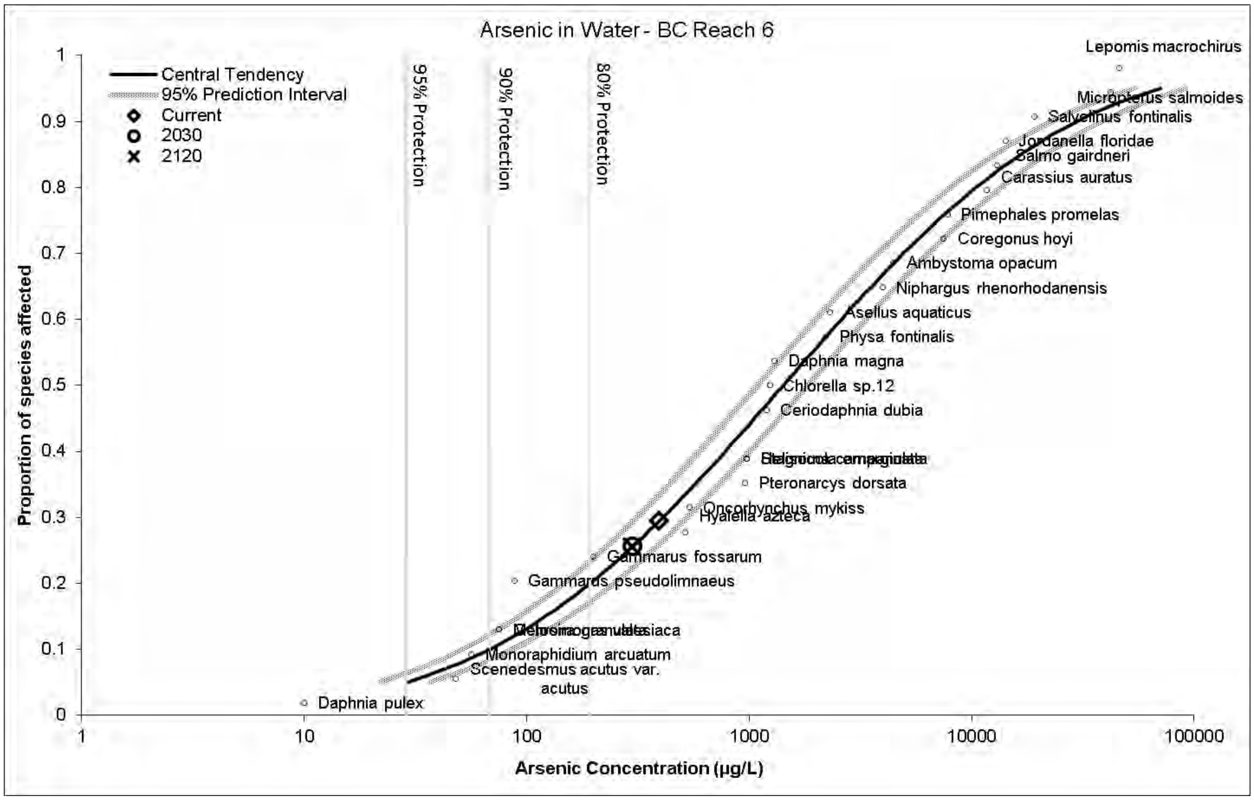


Similar to antimony, current arsenic levels in lower Baker Creek are above the 80% protection level in Reach 1-3, Reach 4-5, and Reach 6 with conditions in Reach 0 that are above the 90% protection level. This indicates there is a potential for 10% to 20% of aquatic biota to be affected. It should be noted that conditions in Upper Baker Creek (Reach 7-11) are above the derived 95% protection level as well.

While arsenic concentrations in the surface water of lower Baker Creek are predicted to decrease in the future, it is expected that concentrations in Reach 1-3, Reach 4-5, and Reach 6 will remain above the 80% protection level, and concentrations in Reach 0 will remain above the 90% protection level. This is illustrated below in Figure 4.28 for arsenic in Baker Creek Reach 6.

Figure 4.28 SSD curve for current and future conditions – arsenic in Baker Creek Reach 6



4.6.1.2 Benthic Invertebrate Community

The WOE evaluation for benthic invertebrates in Baker Creek relies extensively on the results of an assessment conducted by Golder (2013a). This assessment studied the health of the benthic community integrating information on sediment concentrations, sediment toxicity, and benthic invertebrate community composition (abundance, taxonomic richness, and evenness).

Sediment Chemistry

One of the LOEs is a comparison of the sediment chemistry with the appropriate benchmarks; this is shown in Table 4.12 for Baker Creek and Table 4.13 for Back Bay / North Yellowknife Bay. The comparisons shown in this table are based on the current measured data.

It can be seen that the concentrations of several metals in the sediments in Baker Creek are well above the guideline values. In lower Baker Creek (Reach 0-6), cadmium, chromium, and mercury are typically between the ISQG and the PEL, while the other COPC are generally above both benchmarks. In the Upper Baker Creek (Reach 7-11), arsenic has been identified as a potential concern. Although chromium in sediments has also been highlighted, the concentrations are consistent throughout all of Baker Creek and are close to background (as seen in Table 4.13).

Table 4.12 Comparison of sediment concentrations in Baker Creek to guidelines

COPC	Unit	Guideline (mg/kg) [a]		Exposure Point Concentration (mg/kg) [b]				
		ISQG	PEL	Reach 0	Reach 1-3	Reach 4-5	Reach 6 [c]	Baseline Baker Creek (Reach 7-11)
Arsenic	mg/kg	5.9	17	**1555**	**2114**	**2803**	**1716**	**183**
Cadmium	mg/kg	0.6	3.5	0.94	1.4	**4.3**	1.9	0.13
Chromium	mg/kg	37.3	90	43	47	47	54	41
Copper	mg/kg	35.7	197	**1078**	**225**	**1044**	**1142**	17
Lead	mg/kg	35	91.3	**92**	**253**	**1415**	**253**	6.7
Mercury	mg/kg	0.17	0.486	0.18	0.19	0.42	0.23	0.05
Zinc	mg/kg	123	315	**250**	311	**806**	**508**	42

Note:
Although antimony is a COPC in sediment there were no guidelines available for comparison
a – Sediment quality guidelines for the protection of freshwater aquatic life for long-term exposure from the Canadian Council of Ministers of the Environment (CCME 2017). ISQG – Interim Sediment Quality Guideline; PEL – Probable Effects Level.
b – Except where noted the EPC is the 95% UCLM of data collected from various reaches (number of samples range from 10 to 27 in the segment). Includes surficial data collected in 2013, 2014, 2015, 2016; see Appendix K for more detail.
c – Due to limited data in Reach 6 (N=8), the EPC is represented by the estimated 95th percentile.
Values that are above the ISQG are highlighted and values that are also above the PEL are shown in bold.

Table 4.13 Comparison of sediment concentrations in Yellowknife Bay to guidelines

COPC	Unit	Guideline		Exposure Point Concentration (mg/kg)	
		ISQG	PEL	Back Bay / North Yellowknife Bay[b]	Background[c]
Arsenic	mg/kg	5.9	17	**1071**	**27**
Chromium	mg/kg	37.3	90	44	48
Copper	mg/kg	35.7	197	97	40

Note:
Although antimony is a COPC in sediment there were no guidelines available for comparison
a – Sediment quality guidelines for the protection of freshwater aquatic life for long-term exposure from the Canadian Council of Ministers of the Environment (CCME 2017). ISQG – Interim Sediment Quality Guideline, PEL – Probable Effects Level.
b – 95% UCLM of data collected from Back Bay and North Yellowknife Bay (N=50).
c – Average of 5 samples from south Yellowknife Bay (near Horseshoe Island), see Appendix K for more detail.
Values that are above the ISQG are highlighted and values that are also above the PEL are shown in bold.

Sediment concentrations in Yellowknife Bay are elevated above sediment quality guidelines, particularly for arsenic where the concentration exceeds both the ISQG and PEL. Although chromium levels are above the ISQG, the concentrations are close to background. Similarly, copper in sediments is present at levels between the ISQG and PEL in Yellowknife Bay and background locations.

During remediation, the sediments in Baker Creek will be dredged and the sediment quality immediately post remediation will be much improved. As discussed in Section 4.4.2.2, as the water will still contain elevated levels of COPC, in particular arsenic, the sediment concentrations will increase over time. The upstream Baker Creek results are taken to be a reasonable expectation of the potential future conditions expected in lower Baker Creek. The sediment quality in this segment meets the guidelines for all COPC, with the exception of arsenic and chromium, although chromium is at background levels.

Although there is some remediation planned for sediment along the shore near the Giant Mine, this activity has little impact on the expected future sediment concentrations in Yellowknife Bay. However, as the water concentrations in Back Bay / North Yellowknife Bay are low (Figure 4.14), sediment quality is expected to improve slowly over time (as shown in Figure 4.16). The figure shows that even though sediment concentrations will improve over time, they will still remain above sediment quality guidelines and background concentrations for an extended period of time.

Benthic Community

A survey of the benthic community was undertaken as part of a previous study (Golder 2013a). Samples were collected from Baker Creek and the Yellowknife River reference location and organisms were identified to the lowest practical taxonomic level and counted. Density, abundance, and Simpson's evenness index were used to characterize the community. In addition, spatial trends in abundances of invertebrates in the Ephemeroptera, Plecoptera, and Trichoptera (EPT) orders were evaluated as they usually represent the most sensitive component of the benthic community (Golder 2013a). Analysis of depositional benthic invertebrate community identified no obvious differences among benthic invertebrate communities in Baker Creek and the Yellowknife River. Relative densities of major taxonomic groups were highly variable among stations in Baker Creek. All stations had benthic communities dominated by a few taxa. Regression analysis revealed that evenness reflected variation in habitat features rather than sediment COPC concentrations. Overall, the magnitude of the effect of elevated sediment COPC concentrations in Baker Creek sediments on depositional benthic invertebrates was qualitatively described as low (Golder 2013a). Benthic invertebrate communities in erosional habitats of Baker Creek exhibited differences from communities in similar habitats in the Yellowknife River. The erosional benthic invertebrate community within Baker Creek appears to reflect exposure to COPCs from treated effluent rather than historical sediment contamination (Golder 2013a).

These results provide information on the recent to current conditions in Baker Creek. The GMRP will have a significant and substantial impact on the benthic community after dredging occurs. The dredging of Baker Creek will remove the sediment, and it will take a substantial amount of time for habitat to be re-established. It is expected that the habitat will be different from the current situation. Additionally, it is expected that there will be substantial changes to the benthic community as a result of the water treatment plant effluent discharge relocation, as sections of Baker Creek will likely dry out for extended periods in the summer, which will affect the benthic community. Based on these observations, it is difficult to determine the conditions of the benthic communities in Baker Creek in the future.

A survey of the benthic invertebrate community of Yellowknife Bay was conducted in 2013 (Stantec 2014c). It was found that the benthic invertebrate community was variable across the study area. Benthic invertebrate abundance, biomass, richness, diversity, and evenness indicated a relatively diverse benthic community that was typically dominated by a few taxa. Within the near-field area, the benthic community was diverse and generally comprised many different taxa, although the community was dominated by only a few species of amphipods and bivalves. Within the Historical Foreshore Tailings sites and at the downstream reference, diversity was the lowest among sample groups and all sites were dominated by chironomids. This difference in community was attributed to differences in benthic habitat. There was a moderate dissimilarity in the benthic invertebrate community throughout the study area, which was attributed to the noted difference in benthic habitat between sites. It is not expected that these conditions will change substantially in the near future.

Benthic Tissue

As part of a previous study on Baker Creek (Golder 2013a), the chemistry of depositional invertebrate tissues from Baker Creek was compared to those in Yellowknife River. The assessment found that arsenic and antimony from 21 samples from Reach 0 to 6 on Baker Creek were frequently present at concentrations more than 10 times the Yellowknife

River reference mean. In addition, antimony and arsenic were elevated in Upper Baker Creek, with arsenic being over 10 times the reference mean.

Using the Upper Baker Creek station as a surrogate for future conditions, it is predicted that arsenic and antimony will continue to be present at elevated concentrations in invertebrate tissue.

Sediment Toxicity

As part of a previous study on Baker Creek (Golder 2013a), toxicity tests (described in Section 4.5.2.2) were performed on sediment samples from 17 locations in Baker Creek as well as the Yellowknife River reference location. The results of the individual toxicity tests were integrated into a single measure of sediment toxicity as summarized in Table 4.14.

Table 4.14 Summary of results of sediment toxicity testing

Baker Creek Reach Segment	Station	Adverse effects related to sediment toxicity are:
Reach 0	BCSS-DEP-01 BCSS-DEP-03	Possible, but likely limited in magnitude
Reach 1-3	BCSS-DEP-04 BCSS-DEP-08	Probable
	BCSS-DEP-06	Possible
	BCSS-DEP-07	Possible, but likely limited in magnitude
	BCSS-DEP-10	Not anticipated
Reach 4-5	BCSS-DEP-15	Probable
	BCSS-DEP-13	Possible
	BCSS-DEP-11	Possible but likely limited in magnitude
	BCSS-DEP-12 BCSS-DEP-14	Not anticipated
Reach 6	BCSS-DEP-18 BCSS-DEP-20 BCSS-DEP-21	Probable
	BCSS-DEP-19	Possible
Upper Baker Creek	BCSS-DEP-11	Possible but likely limited in magnitude

Source: Golder (2013a).

These toxicity tests provide information on the current conditions of Baker Creek. The GMRP will have a significant and substantial impact on the sediment. Dredging of Baker Creek will remove the sediment and it will take time for deposition to re-establish a sediment layer that can support benthic invertebrates. Once this occurs, the sediment will contain elevated concentrations of COPC, as the water in Baker Creek will still have elevated concentrations of arsenic in particular (Section 4.4.2.2). Using current conditions at Upper Baker Creek as a surrogate for the conditions in lower Baker Creek, it is expected that adverse effects are possible but likely limited in magnitude.

Summary

Table 4.15 summarizes the information from the individual LOEs into an overall WOE evaluation for current conditions. For the assessment of Baker Creek, Golder (2013a) assigned minimal weight to the sediment chemistry LOE since the presence of contaminants in the environment does not necessarily imply an adverse ecological effect. The benthic community LOE was assigned more weight than the sediment toxicity results, as the survey had good spatial coverage of Baker Creek and provides information about actual conditions in the creek with respect to benthic community structure. Similarly, more weight was given to the results of the benthic invertebrate community survey in Yellowknife Bay (Stantec 2014c) in the assessment of potential impacts in this area.

Table 4.15 Summary of assessment of benthic invertebrate community – current

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the benthic invertebrate community.	Sediment chemistry	There are exceedances of sediment benchmarks (both ISQG and PEL) through lower Baker Creek for multiple COPC. The sediment in Yellowknife Bay is elevated compared to background and exceeds sediment benchmarks, although only arsenic exceeds both the ISQG and PEL.
	Benthic community	Benthic invertebrate communities in depositional areas of Baker Creek were no different than the reference area. Impacts of elevated sediment COPC concentrations in Baker Creek sediments on depositional benthic invertebrates can be qualitatively described as low. Benthic invertebrate communities in erosional habitats of Baker Creek exhibit differences from communities in similar habitats in the Yellowknife River. The benthic community of Yellowknife Bay is variable and reflects a relatively diverse benthic community but typically dominated by a few taxa. The difference in community composition was attributed to differences in benthic habitat.
	Benthic tissue concentrations	Concentrations of arsenic and antimony in benthic invertebrate tissue from Baker Creek have been measured at more than 10 times that from the reference location.
	Sediment toxicity	The results of the toxicity testing in Baker Creek show that effects on benthic invertebrates can range from none anticipated (3/17 locations) to probable (6/17 locations).
Overall Assessment: Benthic invertebrates were observed at all stations within Baker Creek, even those where sediment contaminant concentrations were elevated and laboratory sediment toxicity tests results indicated lethality. There were no obvious major differences among (bottom-dwelling) invertebrate communities in Baker Creek and the Yellowknife River. There was however only sporadic occurrence of mayflies in Baker Creek compared to their consistent presence in the Yellowknife River. Overall, the magnitude of the effect of elevated sediment COPC concentrations in Baker Creek on depositional benthic invertebrates can be qualitatively described as low. Benthic invertebrate communities in erosional habitats of Baker Creek do exhibit differences from communities in similar habitats in the Yellowknife River. Despite some elevated concentrations in sediment of Back Bay / North Yellowknife Bay, the benthic community of Yellowknife Bay is variable and reflects a relatively diverse benthic community but typically dominated by a few taxa. The difference in community composition was attributed to differences in benthic habitat.		

Note: Assessment of conditions in Baker Creek is largely obtained from Golder (2013a); see Appendix A for additional detail.

Table 4.16 provides a summary of the expected conditions in the future. As this is a predictive assessment, the LOEs rely on anticipated changes from the GMRP and uses the existing information from the site, particularly from the upper reaches of Baker Creek.

Table 4.16 Summary of assessment of benthic invertebrate community - future

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the benthic invertebrate community	Sediment Chemistry	With the exception of arsenic, the expected future sediment quality in Baker Creek was taken equal to the current data for Reach 7-11. This data indicates that sediment quality in Baker Creek will be expected to meet guidelines or be close to background. Arsenic concentrations are expected to rise above the sediment quality guidelines with time after dredging. The sediment concentrations in Yellowknife Bay are expected to improve over time, but arsenic concentrations will be elevated for a significant period of time.
	Benthic community	There is expected to be significant and substantial impact on the benthic community after the GMRP due to changes in the habitat (from dredging) and changes in flow (may be periods of time during the summer that the creek is dry). It is uncertain what the benthic community will be in the future.
	Benthic tissue concentrations	It is expected that concentrations of arsenic and antimony in benthic invertebrate tissue will continue to be elevated due to remaining elevated COPC concentrations in the sediment.
	Sediment toxicity	Once the sediment layer is re-established in Baker Creek, it is expected that adverse effects on benthic invertebrates are possible but likely limited in magnitude.
Overall Assessment: The GMRP is expected to have a significant impact on benthic invertebrates. Once the community in Baker Creek has re-established, it is possible that there will be some minor effects in invertebrates in erosional habitats, but significant impacts on the benthic invertebrate community from the presence of COPC in sediment are not expected. The benthic community will be affected due to changes in the habitat (from dredging) and changes in flow within Baker Creek (may be periods of time during the summer that the creek is dry). The conditions in Yellowknife Bay are expected to improve over time, albeit slowly. The benthic invertebrate community does not appear to be affected by COPC in sediment, and, therefore, the benthic community is not expected to change with the implementation of the GMRP outside of the limited areas near the Giant Mine where sediment remediation is planned.		

4.6.1.3 Water Column Organisms

The WOE evaluation for water column organisms relies, in part, on the results of an assessment conducted by Golder (2013a). This assessment studied the health of water column organisms, integrating information on water concentrations, periphyton concentrations, and water toxicity testing. These individual LOEs are discussed in this section.

Water Chemistry

The evaluation of potential impacts on water column organisms were based on the comparison of water chemistry to the SSD curves (Section 4.6.1.1). Currently, chloride and sulphate concentrations in all segments of lower Baker Creek may be affecting aquatic biota; however, in the future, chloride and sulphate concentrations in lower Baker Creek are predicted to drop to well below the 95% protection level. For antimony and arsenic, there may be impacts on some aquatic biota, and although this expected to improve in the future, some minor changes to the composition in aquatic biota in Baker Creek may occur. Some of the more sensitive species for exposure to arsenic and sulphate are water column organisms.

Currently, the water quality in Back Bay meets water quality guidelines, and no effects on aquatic organisms are expected. Part of the GMRP will entail moving the effluent treatment plant discharge to Back Bay (Yellowknife Bay in the vicinity of the outlet of Baker Creek). This source to the environment was included in the assessment, and water concentrations were estimated (Section 4.4.2.2). The water quality in Back Bay is expected to meet water quality guidelines, and no effects on aquatic biota are expected (Section 4.6.1.1).

Periphyton Tissue Chemistry

As part of a previous study on Baker Creek (Golder 2013a), the chemistry of periphyton tissues from Baker Creek was compared to those in Yellowknife River. The assessment found that arsenic and antimony from 12 samples from Reach 0 to 5 on Baker Creek were consistently present at concentrations more than 10 times the Yellowknife River reference mean.

In the future, there will be improvement to the water quality (Section 4.4.2.2); however, it is expected that arsenic and antimony will continue to be present at elevated concentrations in periphyton tissue.

Water Toxicity Testing

As part of a previous study on Baker Creek (Golder 2013a), acute and chronic toxicity tests (described in Section 4.5.2.2) were performed on four water samples: three from Baker Creek and one from the Yellowknife River reference location.

None of the Baker Creek water samples were acutely toxic to juvenile rainbow trout or *Daphnia magna*. Neither the upstream Baker Creek water sample (station SNP 43-11 from Reach 7) nor the Yellowknife River reference sample demonstrated chronic toxicity to *Ceriodaphnia dubia* or *Pseudokirchneriella subcapitata*. However, the sample from the outlet of Baker Pond (Reach 6) demonstrated adverse effects in the chronic toxicity test with reduced *Ceriodaphnia* reproduction and inhibition of algal growth. In addition, the sample from the mouth of Baker Creek (Reach 0, SNP 43-5) demonstrated inhibition of algal growth.

These toxicity tests provide information on the current conditions. In the future, water quality for arsenic is expected to improve slightly, while more significant improvements are predicted for antimony, chloride, and sulphate. This will have an effect on the toxicity to water column organisms. The information from the upstream Baker Creek location suggests that there should not be significant toxicity to water column organisms in the future.

Summary

Table 4.17 summarizes the information from the individual LOEs into an overall WOE evaluation. The information on periphyton concentrations provides insight into the bioaccumulation but does not in itself help the decision on potential impacts. The water chemistry and toxicity testing were both considered in the overall WOE and had consistent conclusions regarding the potential for an impact.

Table 4.18 provides a summary of the expected conditions in the future. As this is a predictive assessment, the LOEs rely on estimated concentrations from modelling and considered the existing information from the site, particularly from the upper reaches of Baker Creek.

Table 4.17 Summary of assessment of water column organisms - current

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the water column organisms.	Water Chemistry	Comparing the water chemistry to toxicity of aquatic biota, there are potential impacts due to the presence of elevated levels of chloride, sulphate, antimony, and arsenic. Water column organisms appear sensitive to the presence of sulphate and arsenic.
	Periphyton concentrations	Concentrations of arsenic and antimony in periphyton have been measured at more than 10 times that from the reference location.
	Water toxicity	Toxicity tests conducted on Baker Creek indicate reduced *Ceriodaphnia* reproduction and inhibition of algal growth.
Overall Assessment: It is expected that water column organisms (invertebrates and algae) in Baker Creek are currently being affected by the presence of COPC in the water. The potential for an effect is limited to Baker Creek, as no adverse effects are expected in Yellowknife Bay.		

Table 4.18 Summary of assessment of water column organisms - future

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the water column organisms.	Water Chemistry	The concentrations of all COPC are expected to improve with the implementation of the GMRP. Comparing the water chemistry to toxicity of aquatic biota, there is the potential for some minor effects due to the presence of elevated levels of antimony and arsenic. Water column organisms appear sensitive to the presence of arsenic.
	Periphyton concentrations	Concentrations of arsenic and antimony in periphyton are expected to remain elevated.
	Water toxicity	Using upstream Baker Creek as a surrogate for future conditions, toxicity to water column organisms is not expected.
Overall Assessment: With the implementation of the GMRP the conditions in Baker Creek are expected to improve. There is the potential for some effects due to the presence of antimony and arsenic but this is expected to be minor. There are no potential effects expected in Yellowknife Bay, including consideration of moving the effluent release to Yellowknife Bay near the vicinity of the outlet of Baker Creek.		

4.6.1.4 Fish

The WOE evaluation for fish is based on comparison of water concentrations and fish tissue concentrations to appropriate benchmarks, as well as information on fish health.

Water Chemistry

The assessment of potential impacts on water column organisms is based on the comparison of water chemistry to the SSD curves (Section 4.6.1.1). Currently, chloride and sulphate concentrations in all segments of lower Baker Creek may be affecting aquatic biota (although the concentrations are below levels expected to impact fish). In the future, chloride and sulphate concentrations in lower Baker Creek are predicted to drop to well below the 95% protection level for all aquatic biota. For antimony and arsenic, there may be impacts on some aquatic biota; although the potential for an effect is expected to improve in the future, some minor changes to the composition in aquatic biota in Baker Creek may occur. Some of the more sensitive species for exposure to antimony are fish.

Currently, the water quality in Back Bay meets water quality guidelines, and no effects on fish are expected. Part of the GMRP will result in the effluent treatment plant discharge being moved to Back Bay (Yellowknife Bay in the vicinity of the outlet of Baker Creek). This source to the environment, along with continued discharge from Baker Creek, was included in the estimate of future water concentrations (Section 4.4.2.2). The water quality in Back Bay is expected to continue to meet water quality guidelines, and no effects on fish are expected (Section 4.6.1.1).

Fish Tissue Chemistry

The measured antimony and arsenic concentrations in fish tissues are compared to fish tissue benchmarks. The information for arctic grayling is provided in Table 4.19, ninespine stickleback is in Table 4.20, and slimy sculpin is in Table 4.21. These tables indicate that the highest concentrations were measured in arctic grayling followed by slimy sculpin. Slimy sculpin are present in Baker Creek all through the year, so higher concentrations in this fish compared to ninespine stickleback, which are only present in the summer, is expected (Golder 2013a). A separate study measured arsenic in eight lake whitefish from Baker Pond and the muscle was found to have an average of 0.57 mg/kg ww (Cott et al. 2016). It should be noted that the database of fish tissue concentrations from Baker Creek is limited.

Table 4.19 Comparison of measured arctic grayling arsenic and antimony concentrations to available benchmarks – current – Baker Creek

COPC	Fish Tissue Benchmark [a]		Measured Whole Body Arctic Grayling Summary Statistics							
	NOEC	LOEC	N	N<MDL	Min	Max	Mean	St Dev	Geo Mean	95th Percentile
	mg/kg ww									
Antimony	5	9	4	0	0.50	0.62	0.55	0.05	0.55	0.61
Arsenic	1.5	2	4	0	**7.5**	**16**	**12**	3.6	**12**	**16**

a – Fish tissue benchmarks obtained from CH2MHill (2015).
Values that are above the NOEC are highlighted and values that are also above the LOEC are shown in bold.

Table 4.20 Comparison of measured ninespine stickleback arsenic and antimony concentrations to available benchmarks – current – Baker Creek

COPC	Fish Tissue Benchmark [a]		Measured Whole Body Ninespine Stickleback Summary Statistics							
	NOEC	LOEC	N	N<MDL	Min	Max	Mean	St Dev	Geo Mean	95th Percentile
	mg/kg ww									
Antimony	5	9	4	0	0.04	0.08	0.06	0.02	0.06	0.08
Arsenic	1.5	2	4	0	0.74	1.6	1.0	0.39	0.97	1.5

Note: Summary of measured data from ninespine stickleback obtained from Reach 0 and 1 (Golder 2013a).
a – Fish tissue benchmarks obtained from CH2MHill (2015).
Values that are above the NOEC are highlighted and values that are also above the LOEC are shown in bold.

Table 4.21 Comparison of measured slimy sculpin concentrations to available benchmarks – current – Baker Creek

COPC	Fish Tissue Benchmark [a]		Measured Whole Body Slimy Sculpin Summary Statistics							
	NOEC	LOEC	N	N<MDL	Min	Max	Mean	St Dev	Geo Mean	95th Percentile
	mg/kg ww									
Antimony	5	9	4	0	0.17	0.23	0.21	0.03	0.21	0.23
Arsenic	1.5	2	4	0	**2.4**	**2.7**	**2.6**	0.13	**2.5**	**2.7**

Note: Summary of measured data from ninespine stickleback obtained from Reach 0 and 1 (Golder 2013a).
a – Fish tissue benchmarks obtained from CH2MHill (2015).
Values that are above the NOEC are highlighted and values that are also above the LOEC are shown in bold.

In arctic grayling and slimy sculpin, arsenic concentrations are at levels where effects may occur. Only the maximum measured concentration of ninespine stickleback is above the No Observed Effect Concentration (NOEC), so effects on these small fish are not expected.

A comparison was also completed for potential future fish tissue concentrations (see Appendix K for the estimation approach) as shown in Table 4.22. It is noted that these fish concentrations are based on all resident fish species. This comparison shows that, due to the presence of elevated levels of arsenic, there is the potential for fish effects throughout lower Baker Creek, although to a lesser degree in Reach 0.

Table 4.22 Comparison of predicted 2120 fish concentrations to available benchmarks

COPC	Fish Tissue Benchmark [a]		Baker Creek Reach 0	Baker Creek Reach 1-3	Baker Creek Reach 4-5	Baker Creek Reach 6
	NOEC	LOEC				
	mg/kg ww					
Antimony	5	9	0.16	0.28	0.10	0.08
Arsenic	1.5	2	1.9	**5.0**	**4.1**	**5.7**

Note: Predicted concentrations (see Appendix K).
a – Fish tissue benchmarks obtained from CH2MHill (2015).
Values that are above the NOEC are highlighted and values that are also above the LOEC are shown in bold.

There is information on flesh from large-bodied fish obtained from Baker Creek including northern pike (N=10), lake whitefish (N=31), and burbot (N=2). The tissue benchmarks provided are for whole fish, so they do not directly apply; however, it is noted that, while arsenic levels in lake whitefish are all below the fish tissue benchmark, arsenic levels in burbot and northern pike exceeded the NOEC and Lowest Observed Effect Concentration (LOEC) in several samples.

Mercury was identified as a COPC in sediment. Mercury has the potential to be converted to methylmercury in sediment and then biomagnify through the aquatic food chain, resulting in the highest concentrations in the upper level predatory aquatic receptors (i.e., fish such as northern pike). To examine this potential, the concentration of mercury in fish tissue in Baker Creek was compared to information from background locations and Yellowknife Bay as shown in Figure 4.29 for lake whitefish and Figure 4.30 for northern pike. This comparison shows that the mercury levels in fish tissue in Baker Creek are similar to those found in other locations and, therefore, the elevated mercury in sediment is not resulting in increased concentrations in fish.

Figure 4.29 Comparison of mercury in lake whitefish from Baker Creek to background and Yellowknife Bay

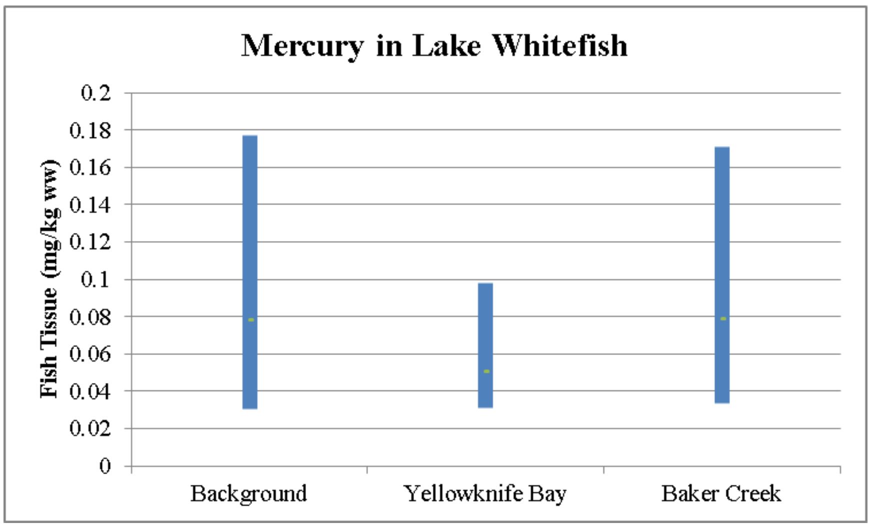

Figure 4.30 Comparison of mercury in northern pike from Baker Creek to background and Yellowknife Bay

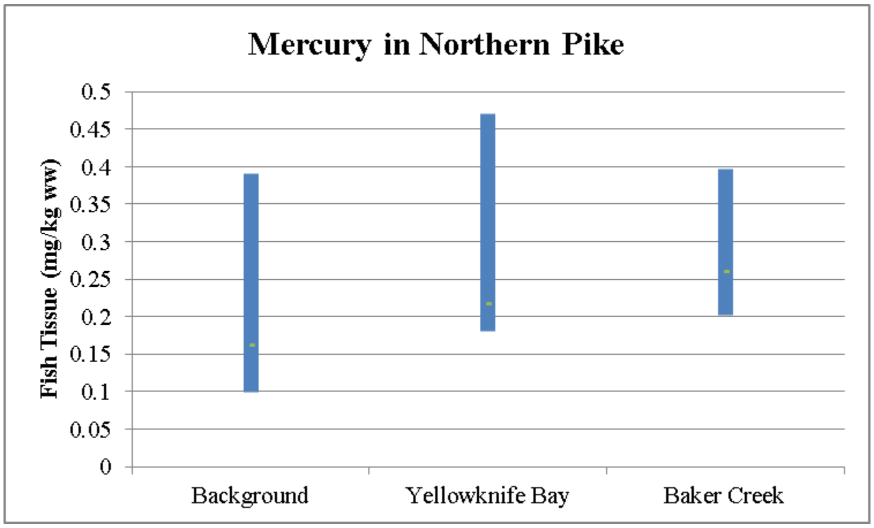

Fish Health

As part of the Environmental Effects Monitoring (EEM) program, a lethal field survey of slimy sculpin and a non-lethal survey of ninespine stickleback were conducted in Baker Creek (exposure area), in two far-field exposure areas, and in two reference locations in Yellowknife River (Golder 2013b). Ninespine stickleback populations differed between the exposure and reference areas in terms of composition of adults and young. Statistical analyses could not be conducted due to the unequal sample sizes (Golder 2013b).

Differences in the health endpoints (e.g., relative liver size, condition) of slimy sculpin were noted in the different phases of the EEM. The differences were generally small and not consistent among years with the exception of male age, relative liver size, and condition. However, these differences were generally below the critical effects size identified by Environment Canada. The results of the slimy sculpin fish surveys were complicated, inconsistent, and had no obvious response pattern (Golder 2013b).

Summary

Table 4.23 summarizes the information from the individual LOEs into an overall WOE evaluation. The water chemistry and fish tissue results were both considered in the overall WOE. The fish tissue LOE has the benefit of accounting for bioaccessibility of

COPC and site-specific conditions (i.e., fish movement, habitat, etc.), but there are limitations in terms of the database of information available for fish from Baker Creek.

Table 4.24 provides a summary of the expected conditions in the future. This is a predictive assessment, and the LOEs rely on estimates of water concentrations and fish tissue in the future.

Table 4.23 Summary of assessment of fish – current

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the fish populations.	Water Chemistry	Comparing the water chemistry to toxicity of aquatic biota, there are potential impacts due to the presence of elevated levels of COPC. In particular, antimony and arsenic may be at concentrations where fish could be affected.
	Fish Tissue	The current measured fish tissue concentrations from Baker Creek are above toxicity benchmarks for arsenic and, therefore, potential effects are possible.
	Fish Health	Fish surveys did not find any obvious response pattern between slimy sculpin in exposure, far-field, and reference areas.
Overall Assessment: It is expected that fish in Baker Creek are currently being affected by the presence of COPC in the water and sediment. The potential for an effect is limited to Baker Creek, as no adverse effects are expected in Yellowknife Bay. The amount of the effect is difficult to determine and fish health surveys have not seen an obvious pattern of response.		

Table 4.24 Summary of assessment of fish – future

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of the fish populations.	Water Chemistry	Comparing the water chemistry to toxicity of aquatic biota, there are potential impacts due to the presence of elevated levels of COPC. In particular, antimony and arsenic may be at concentrations where fish could be affected.
	Fish Tissue	It is anticipated that, in the future, arsenic in fish tissue will continue to be elevated; therefore, there is the potential for fish to be affected.
	Fish Health	No change from the results found in recent surveys is anticipated.
Overall Assessment: With the implementation of the GMRP, it is anticipated that water and sediment quality in Baker Creek will improve. However, arsenic in the water of Baker Creek will continue to be elevated, and this may cause fish in Baker Creek to continue to be affected. The potential for an effect is limited to Baker Creek, as no adverse impacts are expected in Yellowknife Bay.		

4.6.1.5 Wildlife in the Aquatic Environment

The WOE evaluation for wildlife that have aquatic-based diets is primarily based on comparison of exposure to toxicity benchmarks. Information on a previous study of muskrats in Baker Creek was also included. Consideration was given to including other LOEs, such as benchmarks for diet concentrations, but no relevant data were found.

Food Chain Model

This section presents the results for aquatic wildlife receptors. The evaluation used a Screening Index value (SI), which is a comparison of the predicted intake to a toxicity benchmark. Predicted SI values for all aquatic receptors are provided in Table 4.25, Table 4.26, and Table 4.27 for current, 2030, and 2120, respectively, and the full results are presented in Appendix M. Those receptors with an SI above 1 have been identified. Due to the conservative approach taken in the assessment, it should be noted that an SI above 1 does not necessarily mean that there is an effect; rather, it means that the potential for an effect on this receptor from exposure to the COPC cannot be ruled out. Further evaluation is needed, including considering other information sources or obtaining additional information, in order to make a final determination.

For the most part, conditions in Baker Creek improve immediately post-remediation (2030) and then, as the sediments are re-contaminated from the upstream load, conditions deteriorate slowly over time. This trend can be seen in the predicted SI values over time for receptors in Baker Creek, such as muskrat in Baker Pond (Figure 4.31) and merganser in the lower reaches of Baker Creek (Figure 4.32).

In Back Bay, it is predicted that the planned nearshore sediment remediation will have very little effect on overall sediment concentrations in Back Bay. However, overall it is expected that sediments will slowly improve in Back Bay over the long term. This general trend is seen in predicted SI values over time for receptors in Back Bay, such as bat (Figure 4.33) and mink (Figure 4.34).

Figure 4.31 Predicted SI values for muskrat – Baker Pond (Reach 6)

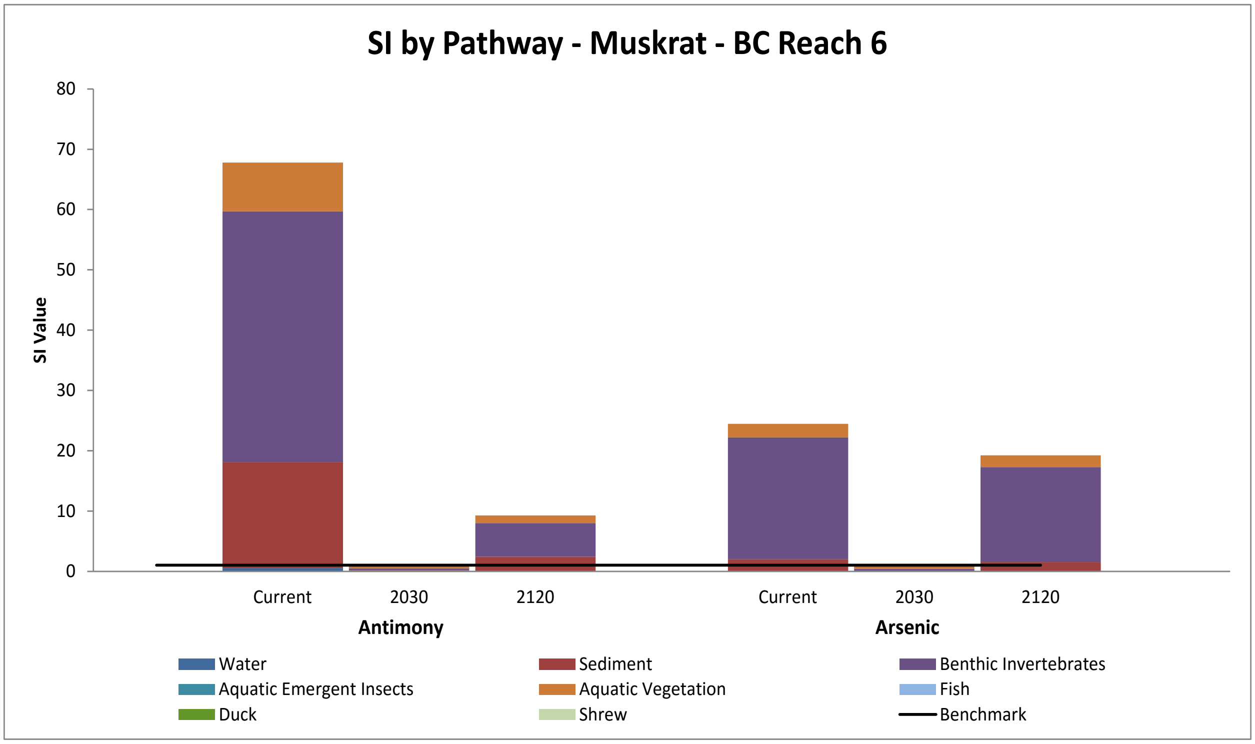

Figure 4.32 Predicted SI values for merganser – lower Baker Creek (Reach 0 to 6)

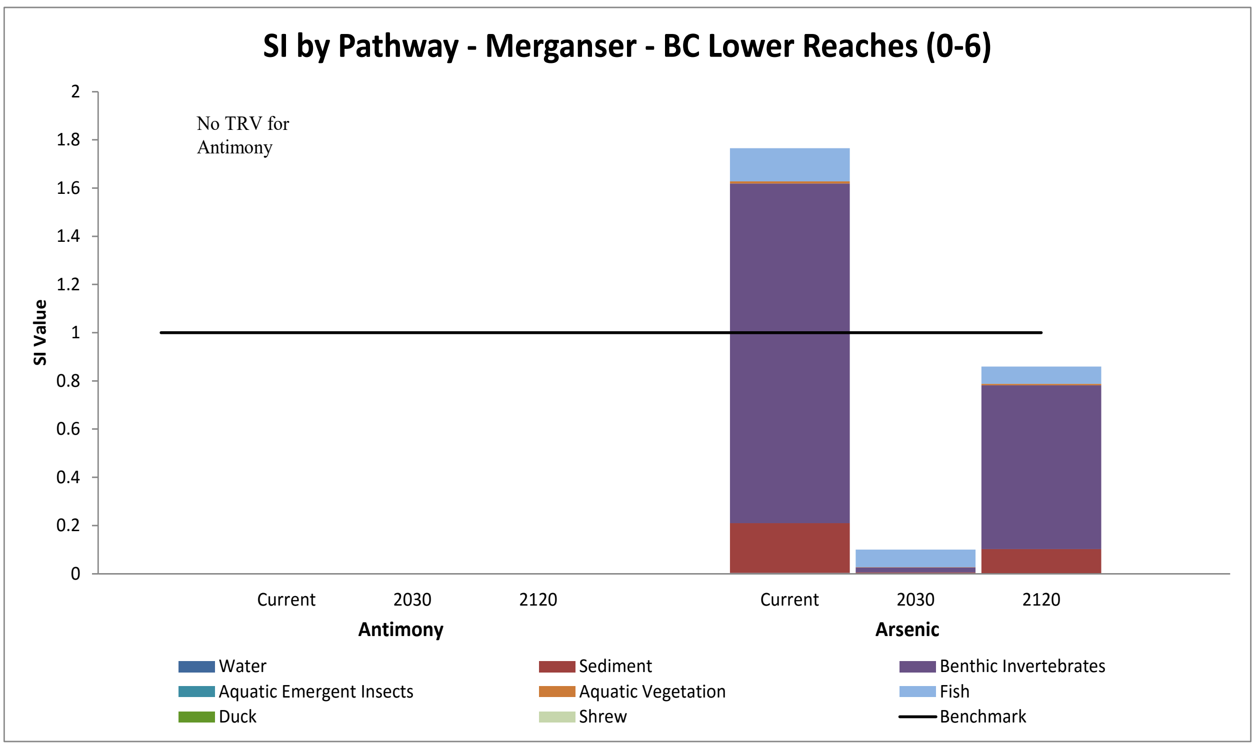

Figure 4.33 Predicted SI values for bat – Back Bay

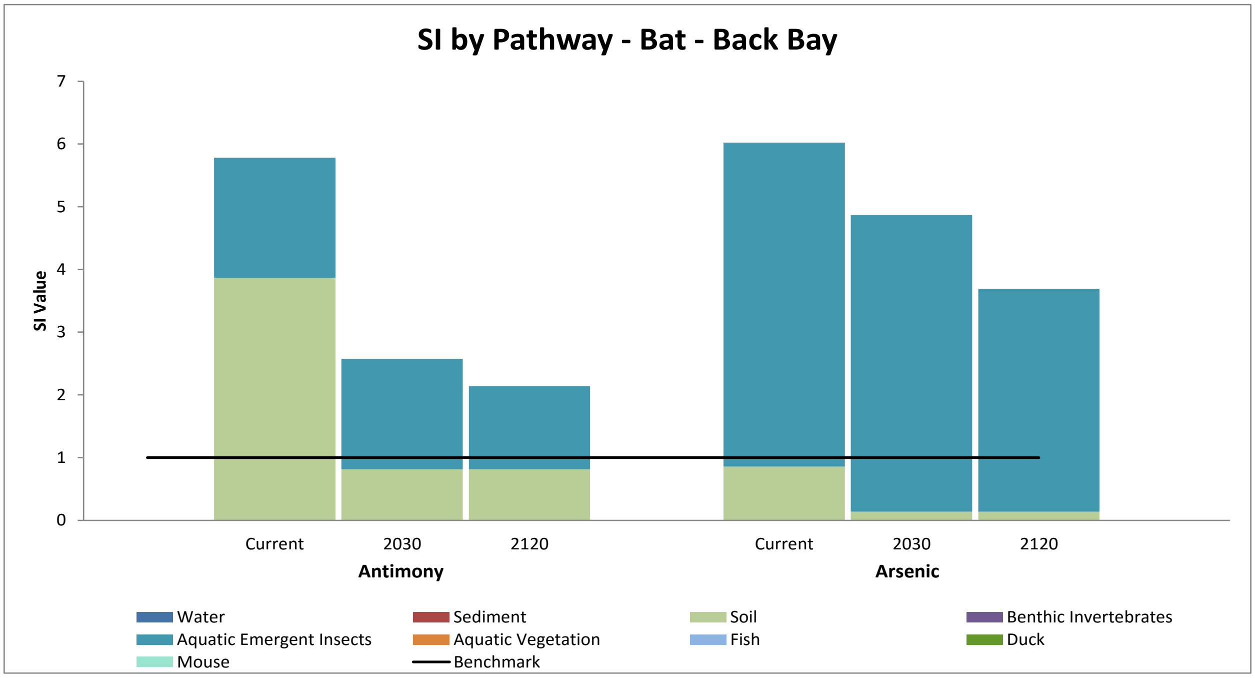

Figure 4.34 Predicted SI values for mink – Back Bay

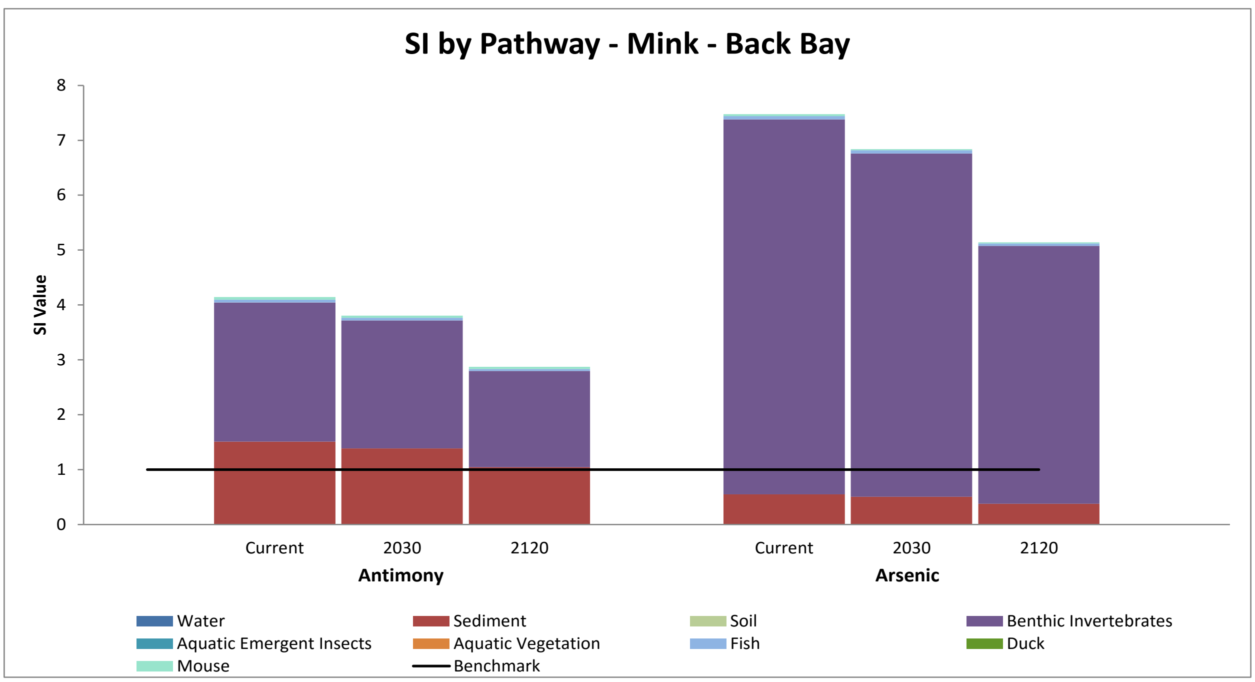

Table 4.25 SI values for wildlife in the aquatic environment – current

Receptor	Location	SI Values	
		Antimony	Arsenic
Muskrat	BC Reach 0	57	22
	BC Reach 1-3	34	30
	BC Reach 4-5	83	39
	BC Reach 6	68	24
	Back Bay	6.9	13
Mink	BC lower Reach (0-6)	37	17
	Back Bay	4.1	7.5
Mallard	BC lower Reach (0-6)	-	14
	Back Bay	-	6.4
Grebe	BC lower Reach (0-6)	-	25
	Back Bay	-	12
Merganser	BC lower Reach (0-6)	-	1.8
	Back Bay	-	0.78
Bat	BC lower Reach (0-6)	26	14
	Back Bay	5.8	6.0
Swallow	BC lower Reach (0-6)	-	10
	Back Bay	-	3.8
Osprey	Back Bay/ Baker Creek	-	0.19

Note: Shaded values exceed the benchmark of 1. There is no TRV for exposure of birds to antimony, so a SI value cannot be calculated.

Table 4.26 SI values for wildlife in the aquatic environment – 2030

Receptor	Location	SI Values	
		Antimony	Arsenic
Muskrat	BC Reach 0	1.8	0.60
	BC Reach 1-3	2.9	0.92
	BC Reach 4-5	1.4	0.82
	BC Reach 6	1.1	0.98
	Back Bay	6.4	12
Mink	BC lower Reach (0-6)	0.54	0.37
	Back Bay	3.8	6.8
Mallard	BC lower Reach (0-6)	-	0.22
	Back Bay	-	5.9
Grebe	BC lower Reach (0-6)	-	0.38
	Back Bay	-	11
Merganser	BC lower Reach (0-6)	-	0.10
	Back Bay	-	0.71
Bat	BC lower Reach (0-6)	6.0	2.1
	Back Bay	2.6	4.9
Swallow	BC lower Reach (0-6)	-	3.6
	Back Bay	-	2.2
Osprey	Back Bay/ Baker Creek	-	0.06

Note: Shaded values exceed the benchmark of 1. There is no TRV for exposure of birds to antimony, so a SI value cannot be calculated.

Table 4.27 SI values for wildlife in the aquatic environment – 2120

Receptor	Location	SI Values	
		Antimony	Arsenic
Muskrat	BC Reach 0	18	7.0
	BC Reach 1-3	33	17
	BC Reach 4-5	12	14
	BC Reach 6	9.3	19
	Back Bay	4.8	9.4
Mink	BC lower Reach (0-6)	11	8.1
	Back Bay	2.9	5.1
Mallard	BC lower Reach (0-6)	-	6.7
	Back Bay	-	4.4
Grebe	BC lower Reach (0-6)	-	12
	Back Bay	-	7.9
Merganser	BC lower Reach (0-6)	-	0.86
	Back Bay	-	0.54
Bat	BC lower Reach (0-6)	11	7.2
	Back Bay	2.1	3.7
Swallow	BC lower Reach (0-6)	-	5.8
	Back Bay	-	1.7
Osprey	Back Bay/ Baker Creek	-	0.11

Note: Shaded values exceed the benchmark of 1. There is no TRV for exposure of birds to antimony, so a SI value cannot be calculated.

Survey and Tissue Concentrations

Two field investigations targeting muskrat (Golder 2004; Jacques Whitford 2003) were undertaken on Baker Creek to support the previous ERA (SENES 2006).

As part of the Golder (2004) program, five muskrat were caught from Baker Creek and eight muskrat were caught from the reference area, Gar Lake. Each of the animals was given a physical examination, and chemical analysis was performed on the muscle, organs, and tails. Table 4.28 shows a summary of arsenic concentrations in muskrat from upstream and downstream of the Giant Mine. As can be seen, the muskrat downstream of the Giant Mine have higher concentrations, indicating that the Giant Mine has an effect on arsenic concentrations measured in the muskrats. Arsenic in tissue concentrations downstream were higher than the reference in all tissues, but it is noted that antimony in the livers of muskrat from Baker Creek were also higher than the reference location.

Despite these findings, the physical examination found that, while some individuals had external scars or broken teeth, all animals appeared to be healthy externally.

Table 4.28 Summary of measured arsenic levels in tissues of muskrat from Baker Creek

Statistic	Measured Arsenic Concentrations (mg/kg ww)					
	Upstream			Downstream		
	Liver	Kidney	Muscle	Liver	Kidney	Muscle
Mean	0.66	0.7	0.24	1.4	2.6	0.51
Maximum	1.18	1.4	0.5	1.8	7.2	0.63

Source: SENES 2006.

The Jacques Whitford (2003) study found 12 active burrows in Baker Creek downstream of the Giant Mine that supported an estimated population of between 66 and 197 animals.

Based on physical examination of study animals (Golder 2004) and field evidence from the population survey (Jacques Whitford 2003), which indicates that there are active dens that support a substantial population of muskrat on Baker Creek, it is unlikely that the presence of COPC in the sediments of Baker Creek are causing serious adverse effects on populations of small terrestrial mammals that have a significant aquatic-based diet. However, there are limitations to the extent that the muskrat study can be included in the assessment. The survey was only an external examination and did not fully explore potential effects on endpoints such as reproduction. The survey of burrows did not include a reference site, so it is uncertain whether the muskrat density has been affected. In addition, these studies were conducted over 10 years ago, and although contaminant levels are expected to change slowly over time, enough time has passed to change conditions.

Summary

Table 4.23 summarizes the information from the individual LOEs into an overall weight of evidence evaluation. The food chain model was the primary LOE as it includes a range of receptors. The muskrat survey provides valuable information that, although the animals are being exposed to COPC, no adverse effects have been noted, but the survey only includes muskrat and there are limitations.

Table 4.24 provides a summary of the expected conditions in the future. This is a predictive assessment, and the LOEs rely on estimates of water and sediment concentrations that will be directly affected by the GMRP as well as anticipated changes to the concentrations in the biological environment. It should be noted that the dredging of Baker Creek will affect the habitat and, thus, will change the use of Baker Creek by many of these receptors. In addition, moving the effluent treatment plant discharge may result in Baker Creek being dry for periods during the summer, and this will also affect the use of this watercourse by wildlife.

Table 4.29 Summary of assessment of wildlife in aquatic environment – current

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of wildlife that use the aquatic resources on the site.	Food chain model	SI values above 1 were noted for most receptors at most locations for both COPC. Highest SI values were noted for muskrat in lower Baker Creek.
	Survey	Studies investigating muskrat physical health, population density, and chemistry found that the Giant Mine is affecting tissue chemistry; however, all sampled animals were healthy, and there appears to be a substantial muskrat population on lower Baker Creek.
Overall Assessment: While COPC levels in the environment indicate that there is potential for adverse effects to wildlife in the aquatic environment near to the Giant Mine (including Baker Creek and Back Bay), evidence of this was not observed during the muskrat studies; however, data are limited.		

Table 4.30 Summary of assessment of wildlife in aquatic environment – future

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of wildlife that use the aquatic resources on the site.	Food chain model	Due to remediation of the sediments in Baker Creek and Back Bay there is some predicted improvement in 2030 where there are fewer receptors with SI values above 1; however, the sediment levels in lower Baker Creek are predicted increase over time and by 2120 SI values above 1 are predicted for most receptors in most locations for both COPC.
	Survey	The studies on muskrat show that, although they are being exposed, there are no obvious effects; however, data are limited.
Overall Assessment: The GMRP will improve the conditions in Baker Creek although there may still be the potential for adverse effects to wildlife in the aquatic environment near to the Giant Mine (including Baker Creek and Back Bay). The dredging of Baker Creek will affect the use of this watercourse in the short term, and changes in flow within Baker Creek (may be periods of time during the summer that the creek is dry) will also have an effect on the presence of wildlife and how they use the system.		

4.6.1.6 Terrestrial Vegetation

The WOE evaluation for terrestrial vegetation is based on comparison of soil concentrations and vegetation concentrations to appropriate benchmarks. Consideration was given to other LOEs, such as plant health and diversity surveys, but no information was available.

Soil Chemistry

Comparison of soil concentrations at the Giant Mine to the ecological component of soil quality guidelines is presented in Table 4.31 and Table 4.32 for current and future timelines, respectively. Soil concentrations presented for current conditions are the EPCs selected based on calculating the 95% UCLM of all available data, while soil concentrations for the future were predicted for remediated conditions in the disturbed areas and tailings basins at the Giant Mine. These EPCs are discussed in Section 4.4.2, and the full set of EPCs is presented in Appendix K.

As can be seen, antimony, arsenic, and manganese soil EPCs are above the selected benchmarks for all quadrants of the Giant Mine, for both current and future conditions. Copper soil EPCs are above the guideline in Trapper Lake North, East of Baker Creek, and South Baker Creek, while zinc EPCs are below the guideline in all quadrants except East of Baker Creek, for both current and future conditions.

Table 4.31 Comparison of measured soil concentrations to soil guidelines – current

COPC	Soil Guideline [a]	Soil EPCs [b]			
		Trapper Lake North	West of Baker Creek	East of Baker Creek	South Baker Creek
	mg/kg dw				
Antimony	20	**36**	**165**	**306**	**120**
Arsenic	17	**667**	**2,519**	**4,575**	**3,519**
Copper	63	**92**	56	**271**	**104**
Manganese	220 [c]	**1,014**	**807**	**1,072**	**1,159**
Zinc	200	94	100	**267**	133

Note:

a – Ecological component (direct contact) from CCME guidelines (CCME 2017). Due to lack of specific information from CCME, for antimony, the value was adopted from the Ontario Ministry of the Environment and Climate Change (MOE 2011).

b – Current soil EPCs are the 95% UCLM of available data.

c – No regulatory value available; the Eco-SSL (U.S. EPA 2007b) for plants is provided for comparison.

Table 4.32 Comparison of predicted soil concentrations to soil guidelines – future

COPC	Soil Guideline [a]	Soil EPCs [b]			
		Trapper Lake North	West of Baker Creek	East of Baker Creek	South Baker Creek
	mg/kg dw				
Antimony	20	**36**	**165**	**101**	**112**
Arsenic	12	**667**	**2,519**	**1,621**	**2,818**
Copper	63	**92**	56	**126**	**104**
Manganese	220 [c]	**1,014**	**807**	**995**	**1,501**
Zinc	200	94	100	**253**	133

Note:
a – Ecological component (direct contact) from CCME guideline (CCME 2017). Due to lack of information, for antimony, the value was adopted from the Ontario Ministry of the Environment and Climate Change (MOE 2011).
b – Calculated future soil concentrations based on soil/tailings component of the Giant Mine Remediation Plan.
c – No regulatory value available; the Eco-SSL (U.S. EPA 2007b) for plants is provided for comparison.

Tissue Concentrations

Measured foliage concentrations from the Giant Mine collected by Golder (2016g) as part of a program to fill in gaps for this ERA were compared to concentrations representative of phytotoxic levels. Foliage summary statistics along with phytotoxic concentration ranges from literature are shown in Table 4.33, Table 4.34, Table 4.35, and Table 4.36 for Trapper Lake North, West of Baker Creek, East of Baker Creek, and South Baker Creek, respectively.

Measured levels of antimony, copper, and zinc are all below the phytotoxic ranges, while maximum and 95th percentile concentrations of arsenic and manganese are above the reported phytotoxicity ranges. In East of Baker Creek (Table 4.35), the 95% UCLM is above the phytotoxic range, which indicates that more wide-spread effects on vegetation in this quadrant could be expected. As this portion of the site includes the former mill complex, elevated concentrations in this area are expected. It is noted that the vegetation samples sent for analysis were observed to be healthy (i.e., no signs of disease, yellowing leaves, breakage or missing leaves) (Golder 2016g). This indicates that arsenic concentrations up to 284 mg/kg ww do not necessarily translate into phytotoxic effects.

A similar comparison was made for the future using predicted foliage concentrations. Predicted foliage concentrations and the phytotoxic ranges are presented in Table 4.37. All predicted concentrations are well below the phytotoxic ranges for antimony, copper, and zinc, while predicted arsenic concentrations all fall within the phytotoxic ranges.

Predictions for manganese are all within the phytotoxic range with the exception of foliage in South Baker Creek, which are predicted to be higher than the ranges noted in literature.

Table 4.33 Comparison of measured foliage concentrations to phytotoxic levels – current – Trapper Lake North

Summary

Table 4.47 summarizes the information from the individual LOEs into an overall weight of evidence evaluation. The measured vegetation concentrations compared to phytotoxicity benchmarks LOE was assigned more weight than the soil chemistry, as it is based on a reasonable sample size with good spatial coverage of Giant Mine and reflects the actual uptake by vegetation.

Table 4.48 provides a summary of the expected conditions in the future. This is a predictive assessment and the LOEs rely on estimates of soil and vegetation concentrations in the future. The concentrations in vegetation were estimated based on our current knowledge of potential uptake based on the measured data.

Table 4.37 Comparison of predicted foliage concentrations to phytotoxic levels – future

COPC	Phytotoxic Range	Trapper Lake North	West of Baker Creek	East of Baker Creek	South Baker Creek
	mg/kg ww				
Antimony	65 [a]	0.21	0.31	0.27	0.28
Arsenic	1.3-11 [a]	2.4	4.4	3.6	4.6
Copper	8.6-43 [a]	1.5	1.5	1.5	1.5

Table 4.38 Summary of assessment of terrestrial vegetation – current

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of vegetation communities on the site.	Soil Chemistry	Soil concentrations are above the selected benchmark across most of the site for several COPC (antimony, copper, arsenic and manganese).
	Tissue Concentrations	Measured vegetation levels of arsenic and manganese are within and, periodically, above the ranges in literature were observed. There were no obvious signs of stress in the vegetation sampled from the site.
Overall Assessment: The data suggest that there may be some effects on terrestrial vegetation, particularly in the East of Baker Creek quadrant. However, high concentrations in vegetation were not necessarily associated with obvious signs of stress.		

Table 4.39 Summary of assessment of terrestrial vegetation – future

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of vegetation communities on the site.	Soil Chemistry	Soil concentrations are anticipated to be above the selected benchmark across most of the site for several COPC (antimony, copper, arsenic and manganese).
	Tissue Concentrations	Estimated vegetation concentrations of arsenic and manganese are generally within the ranges in literature for phytotoxicity.
Overall Assessment: With the implementation of the GMRP the soil quality at the Giant Mine is expected to improve. There is some possibility of some effects on terrestrial vegetation but wide-spread effects are not expected.		

4.6.1.7 Wildlife in the Terrestrial Environment

The weight of evidence evaluation for wildlife present in the terrestrial environment was primarily based on comparison of exposure to toxicity benchmarks. Information on tissue levels from small mammals obtained from Giant Mine is also considered. Consideration was given to including other LOEs such as benchmarks for diet concentrations and population surveys, but no relevant data were found.

Food Chain model

This section presents the results for terrestrial wildlife receptors. The evaluation used an SI, which is a comparison of the predicted intake to a toxicity benchmark. Predicted SI values for all terrestrial receptors are provided in Table 4.40 and Table 4.41 for current and future (post-remediation) timeframes, respectively, and the full results are presented in Appendix M. Those receptors with an SI above 1 have been identified. Due to the conservative approach taken in the assessment (i.e., use of a NOAEL to calculate an SI), it should be noted that an SI above 1 does not necessarily mean that there is an effect; rather, it means that the potential for an effect on this receptor from exposure to the COPC cannot be ruled out. Further evaluation is needed within an WOE approach, such as considering other information sources or obtaining additional information, in order to make a final determination.

The results show that the SI values for antimony, arsenic, and manganese are well above 1 for most of the selected receptors. A higher SI number suggests a greater risk of an effect. For many of the receptors, the incidental intake of soil is an important pathway of exposure to antimony and arsenic. Soil is consumed by wildlife as they feed, but the actual rates are not well known. The assumptions used in this assessment are generally taken from Environment Canada guidance (FCSAP 2012b). Terrestrial vegetation (foliage) is an important route of exposure for manganese; measured data were used in the assessment of current conditions for this pathway.

The highest SI values were calculated for shrews, small mammals that consume terrestrial insects (e.g., beetles, spiders, insect larvae). Since there are no direct measurements of concentrations of COPCs in insects from the site, it was assumed for this assessment that insects have the same concentrations as those found in terrestrial vegetation. A review of available information for arsenic (Appendix K) suggests that this is a reasonable assumption. There is a lack of suitable information for other COPC such as antimony. Bats and swallows that eat insects also have high SI values.

It is noted that animals may adapt to living in areas of high concentrations. For example, a study was conducted on several birds (gray jay, American tree sparrow, dark-eyed junco, yellow-rumped warbler, and spruce grouse) in the Yellowknife area (Koch et al. 2005), and the primary arsenic species detected in two of the bird species studied was arsenobetaine. As discussed in the paper, arsenobetaine is not normally formed or retained by terrestrial animals. Thus, the birds were thought to be highly adapted and were able to form and/or retain this relatively nontoxic arsenic compound.

Table 4.40 SI values for terrestrial receptors – current

Receptor	Location	SI Values				
		Antimony	Arsenic	Copper	Manganese	Zinc
Mouse	Trapper Lake North	2.2	0.99	0.10	2.1	$4.3x10^{-3}$
	West of Baker Creek	7.5	2.7	0.09	1.6	$4.4x10^{-3}$

Falcon	Entire Site	-	0.13	0.04	$5.9x10^{-3}$	0.03
Owl	Entire Site	-	0.55	0.13	0.02	0.05
Lynx	Entire Site	1.4	0.55	0.04	0.03	0.02

Note: Shaded values exceed the benchmark of 1. There is no TRV for exposure to birds to antimony, so an SI value cannot be calculated.

The review of available information on the potential toxicity of antimony did not reveal any information on avian toxicity; thus, no SIs for antimony have been calculated for birds. This is a source of uncertainty in the assessment. If it is assumed that birds are as sensitive to antimony as mammals (i.e., same TRVs), many of the SI values would be above 1.

The potential effects are generally limited to the small animals that would live in a small portion of the site. For larger animals that would roam across the site and beyond, only antimony was predicted to be a potential issue. This is again primarily due to the direct ingestion of soil. Exposure to arsenic is not anticipated to be a concern for these receptors.

The GMRP includes covering the tailings areas and remediation of disturbed soils in the former Mill Complex (East of Baker Creek); this is expected to result in a decrease in the soil concentrations at the Giant Mine, primarily in the East of Baker Creek and South Baker Creek quadrants.

There are no remediation activities planned in the Trapper Lake North quadrant and, therefore, the concentrations of antimony and arsenic will remain unchanged in the future. This is observed in Figure 4.35 (hare), Figure 4.36 (bat), and Figure 4.37 (shrew), where the current and future SI values are the same. In West Baker Creek, there is also very little change as a result of the GMRP.

There are expected to be some improvements to soil quality in South Baker Creek, as a result of GMRP and more substantial changes in East of Baker Creek. This improvement is seen to result in decreased future SI values for terrestrial receptors in these quadrants as seen in the examples shown below for hare, bat, and shrew. Receptors with larger home ranges are also expected to see reduced SI values; this is seen for fox (Figure 4.48) and lynx (Figure 4.47). The SI values for the receptors in the future scenario, however, remain well above 1.

Tissue Concentrations

Golder (2016) collected small mammals from across the Giant Mine to infill data gaps identified for this ERA. Species collected consisted of deer mouse, northern red-backed vole, and shrew. Summary statistics for whole body concentrations observed in small mammals collected from each of the Giant Mine quadrants are shown in Table 4.42, Table 4.43, Table 4.44, and Table 4.45 for Trapper Lake North, West of Baker Creek, East of Baker Creek, and South Baker Creek, respectively.

Available toxic tissue benchmarks were available for arsenic and copper for liver and kidney. No benchmarks were identified for other COPC or tissues. The use of organ benchmarks, however, is conservative in this case, as whole body concentrations include organs and bones, which are known to accumulate metals.

As can be seen, all copper measurements are well below the two benchmarks with the highest concentration at 4.9 mg/kg ww. Similarly, arsenic concentrations in small mammals from Trapper Lake North, East of Baker Creek, and South Baker Creek were below the arsenic toxic tissue concentrations. Out of the 18 mammals collected from West of Baker Creek, two were within the toxic tissue concentration ranges with concentrations of 28 mg/kg ww and 5.1 mg/kg ww. The maximum measured concentration of 28 mg/kg ww (sample 16-GIANT-RV-21) was collected from the same location as another vole (16-GIANT-RV-20) where the arsenic concentration was measured at 3.5 mg/kg ww. This shows the variability of COPC concentrations in tissues. It should be noted that there were no obvious signs of stress in the red vole with the elevated concentration, and it was one of the largest of the small mammal samples collected.

Table 4.42 Comparison of measured small mammal concentrations to toxic tissue concentrations – current – Trapper Lake North

A similar comparison was made to toxic tissue concentration levels for the future using predicted small mammal (shrew and mouse) concentrations; this comparison is shown in Table 4.46. As can be seen, all arsenic and copper concentrations in small mammals are predicted to be below the toxic tissue concentrations.

Table 4.46 Comparison of measured small mammal concentrations to toxic tissue concentrations – future

Summary

Table 4.47 summarizes the information from the individual LOEs into an overall WOE evaluation. For many of the receptors, the food chain modelling is the only information available; however, for small mammals the tissue concentrations provide a valuable LOE. In addition to the LOEs identified, it is noted that the field program was able to obtain small mammals and no obvious signs of toxicity were noted. As this program was not a robust survey of the small mammal population it was not included as a formal LOE, but is considered as additional information.

It is also noted that a recent study examined biochemical responses to snowshoe hare in the area near Giant Mine compared to a reference location (Amuno et al. 2018b, 2018a).

Overall these two studies indicate that hares are exposed to arsenic and that there are biochemical changes. The endpoints examined in these studies however, are not suitable for evaluating population-level effects within an ERA. Appendix L provides some additional information on these studies.

Table 4.48 provides a summary of the expected future conditions. This is a predictive assessment, and the LOEs rely on estimates of soil concentrations that will be directly affected by the GMRP as well as anticipated changes to the concentrations in the biological environment.

Table 4.47 Summary of assessment of wildlife in terrestrial environment – current

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of wildlife that use the terrestrial resources on the site.	Food chain model	The food chain model indicated that antimony, arsenic, and manganese are at concentrations at the Giant Mine where effects in wildlife may occur. The potential for effects was identified in all four quadrants of the site. The animals with the greatest risk of an effect were small animals, including mice and hare, but were particularly a concern for those that consume terrestrial insects (shrew, bat, swallows). The potential effects are generally limited to the small animals, only antimony was predicted to be a potential issue for larger receptors such as lynx and fox.
	Tissue Concentrations	Comparison of measured concentrations in tissue of small mammal (whole body) to available toxic tissue concentrations showed that most values are well below the benchmarks with only a few exceptions.
Overall Assessment: There is the potential for the smaller animals at the site to be affected by COPC. This is a particular concern for those animals that consume insects. As animals can adapt to living in areas of high concentrations, the effects may not be as significant as predicted. The measured small mammal tissue showed that effects across the site are not expected, and small mammals were abundant at the site, supporting that the food chain model LOE is conservative.		

Table 4.48 Summary of assessment of wildlife in terrestrial environment – future

Assessment Endpoint	Line of Evidence	Measurement Endpoint
Maintenance of the health and ecological integrity of wildlife that use the terrestrial resources on the site.	Food chain model	Similar to for the current estimates, the food chain model indicates a potential concern for most receptors across the site for antimony, arsenic, and manganese in the future. The highest SI values were noted for the shrew and other small animals. With the implementation of the GMRP, the SI values for receptors in East of Baker Creek are the ones to show the largest improvement, but are still above 1.
	Tissue Concentrations	Comparison of predicted small mammal (shrew and mouse) concentrations to toxic tissue concentrations showed that predictions for all quadrants of the Giant Mine are expected to be below the benchmarks.
Overall Assessment: There is the potential for small animals to be affected by COPC levels at the site. This is a particular concern for those animals that consume insects. The measured small mammal tissue showed that effects across the site are not expected, indicating that the food chain model LOE is conservative.		

4.6.1.8 Overall Summary

Table 4.49 provides an overall summary of the WOEs for the assessment endpoints.

Table 4.49 Summary of results of ERA

Assessment Endpoint	Current	Future
Maintenance of the health and ecological integrity of the benthic invertebrate community.	The magnitude of the effect of elevated sediment COPC concentrations in Baker Creek on depositional benthic invertebrates can be qualitatively described as low. Benthic invertebrate communities in erosional habitats of Baker Creek do exhibit differences from communities in similar habitats in the Yellowknife River. Despite some elevated concentrations in sediment of Back Bay/North Yellowknife Bay, the benthic community of Yellowknife Bay is variable and reflects a relatively diverse benthic community but typically dominated by a few taxa. No population-level adverse effects due to the presence of COPC in sediment were observed.	The GMRP is expected to have a significant impact on benthic invertebrates. Once the community in Baker Creek has re-established, it is possible that there will be some minor effects on invertebrates in erosional habitats, but significant impacts on the benthic invertebrate community from the presence of COPC in sediment are not expected. The benthic community will be affected due to changes in the habitat (from dredging) and changes in flow within Baker Creek (may be periods of time during the summer that the creek is dry). The conditions in Yellowknife Bay are expected to improve over time, albeit slowly. The benthic community is not expected to change with the implementation of the GMRP outside of the limited areas near the Giant Mine where sediment remediation is planned.
Maintenance of the health and ecological integrity of the water column organisms.	It is expected that water column organisms (invertebrates and algae) in Baker Creek are currently being affected by the presence of COPC in the water. The potential for an effect is limited to Baker Creek as no adverse effects are expected in Yellowknife Bay.	With the implementation of the GMRP the conditions in Baker Creek are expected to improve. There is the potential for some effects due to the presence of antimony and arsenic, but this is expected to be minor. There are no potential effects expected in Yellowknife Bay, including consideration of moving the effluent release to Yellowknife Bay near the vicinity of the outlet of Baker Creek.
Maintenance of the health and ecological integrity of the fish populations.	It is expected that fish in Baker Creek are currently being affected by the presence of COPC in the water and sediment. The potential for an effect is limited to Baker Creek, as no adverse effects are expected in Yellowknife Bay. The level of the effect is difficult to determine and fish health surveys have not seen an obvious pattern of response.	With the implementation of the GMRP, it is anticipated that water and sediment quality in Baker Creek will improve. However, arsenic in the water of Baker Creek will continue to be elevated, and this may cause fish in Baker Creek to continue to be affected. The potential for an effect is limited to Baker Creek, as no adverse impacts are expected in Yellowknife Bay.
Maintenance of the health and ecological integrity of wildlife that use the aquatic resources on the site.	While COPC levels in the environment indicate that there is potential for adverse effects to wildlife in the aquatic environment near to the Giant Mine, evidence of this was not observed during the muskrat studies; however, data are limited.	The GMRP will improve the conditions in Baker Creek, although there is still the potential for adverse effects to wildlife in the aquatic environment near to the Giant Mine. The dredging of Baker Creek will affect the use of this watercourse in the short term, and changes in flow within Baker Creek (may be periods of time during the summer that the creek is dry) will also have an effect on the presence of wildlife and how they use the system.

Assessment Endpoint	Current	Future
Maintenance of the health and ecological integrity of vegetation communities on the site.	The data suggest that there may be some effects on terrestrial vegetation, particularly in the East of Baker Creek quadrant. High concentrations in vegetation were not necessarily associated with obvious signs of stress.	With the implementation of the GMRP, the soil quality at the Giant Mine is expected to improve. There is the possibility of some effects on terrestrial vegetation, but widespread effects are not expected.
Maintenance of the health and ecological integrity of wildlife that use the terrestrial areas on the site.	There is the potential for the smaller animals at the site to be affected by COPC. This is a particular concern for those animals that consume insects. As animals can adapt to living in areas of high concentrations, the effects may not be as significant as predicted. The measured small mammal tissue showed that effects across the site are not expected, supporting that the results from the food chain model are conservative.	With the implementation of the GMRP, there will continue to be the potential for small animals to be affected by COPC levels at the site. This is a particular concern for those animals that consume insects. The predicted small mammal tissue results show that effects across the site are not expected, indicating that the results from the food chain model are conservative.

4.6.2 Sensitivity Analyses

A sensitivity analysis was undertaken to look at the sensitivity of the ERA results to changes in some of the assumptions with higher associated uncertainty. As a conservative approach was taken in the assessment, the sensitivity analysis examined some of the assumptions to determine whether different assumptions would affect the conclusions of the assessment. The full sensitivity analysis discussion can be found in Appendix N. The sensitivity analysis looked at the following factors:

- Water/sediment model predictions (Case A) – Future water and sediment levels resulting from the Giant Mine Remediation plan were modelled, taking into account all available information. There was, however, uncertainty in some areas of the model where information was limited. In addition, factors such as climate change may have an impact on future water and sediment quality that was not accounted for in the predictions. In the DAR (INAC/GNWT 2010), the CCCSN assessment indicated that precipitation may increase by up to 15% over the next 50 years. As the future assessment was evaluating a 100 year scenario, it was assumed the change in precipitation could be as high as 30%. The effect of climate change on the future conditions at the Giant Mine is difficult to quantify (Appendix N provides further discussion on the potential changes to water and sediment quality due to climate change). For this reason, this sensitivity case looked at varying water and sediment predictions by 30% in Lower Baker Creek and 10% in Back Bay.
- Bioaccessibility and arsenobetaine assumptions (Case B)
    - Case B1 – All available arsenic data was used to derive bioaccessibility and arsenobetaine assumptions for use within the ERA. This is a reasonable approach, as not all arsenic in the environment is available or toxic. The sensitivity analysis examined the effect of using 100% bioaccessibility and 100% toxic for arsenic.
    - Case B2 – No bioaccessibility data were available for COPC besides arsenic. While it is not realistic, in the absence of information, bioaccessibility for antimony, copper, manganese, and zinc were assumed to be 100%. This sensitivity looked at setting soil antimony bioaccessibility to 30%. This value seemed reasonable based on information from other sites (Li et al. 2014).

- Basis for derivation of TRVs (Case C) – The TRVs selected for use in the ERA were taken from the FCSAP guidance and are based on NOAELs. This is a conservative approach that is protective of any species, including species-at-risk such as the little brown bat and barn swallow. This sensitivity analysis looked at the use of TRVs based on LOAELs. The use of LOAELs can be used to evaluate population-level effects and is supported by other regulatory agencies (e.g., MOECC have used LOAELs in the derivation of soil quality guidelines (MOE 2011)).
- Soil remediation assumptions (Case D) – Future soil concentrations for regions of the Giant Mine were developed based on the Giant Mine Remediation Plan. There is uncertainty in implementation details at this point and so this sensitivity analysis looked at if the concentrations in the remediated soils are 20% lower.
- Basis for terrestrial insect concentrations (Case E) – As there are no direct measurements of insects from the site, for this assessment, it was assumed that insects are present at the same concentration as vegetation. This sensitivity analysis looked at setting terrestrial insects equal to the bioavailable fraction of arsenic in foliage and not the entire amount of arsenic as was done in the ERA.

Selected examples illustrating the results of the sensitivity analysis are shown below in Figure 4.49, Figure 4.50, and Figure 4.51.

Figure 4.49 Sensitivity analysis results for muskrat in Baker Creek Reach 6 – 2120 - arsenic

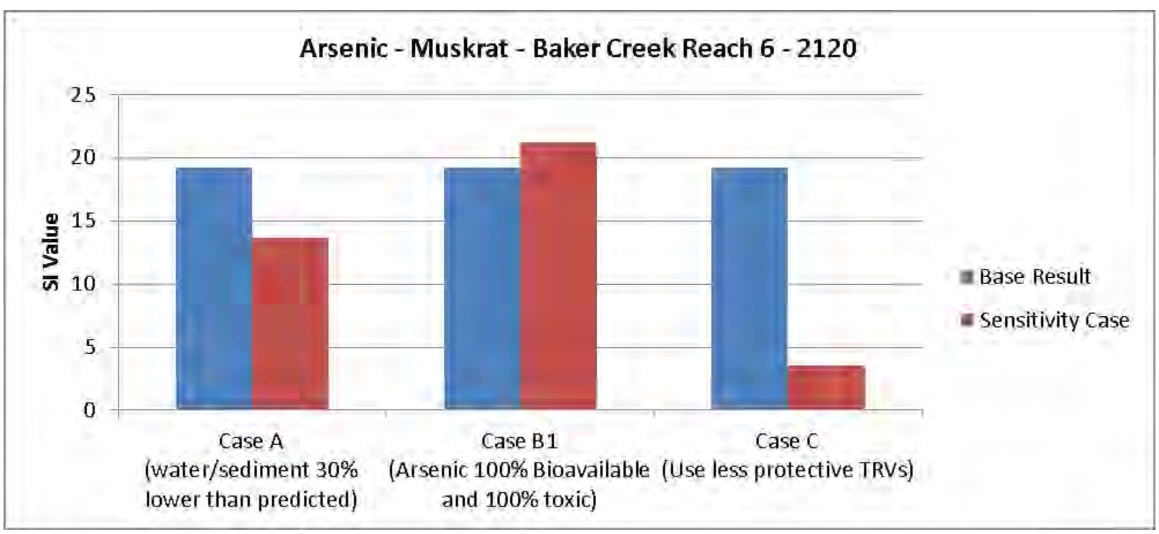

Figure 4.50 Sensitivity analysis results for shrew in East of Baker Creek – future – arsenic

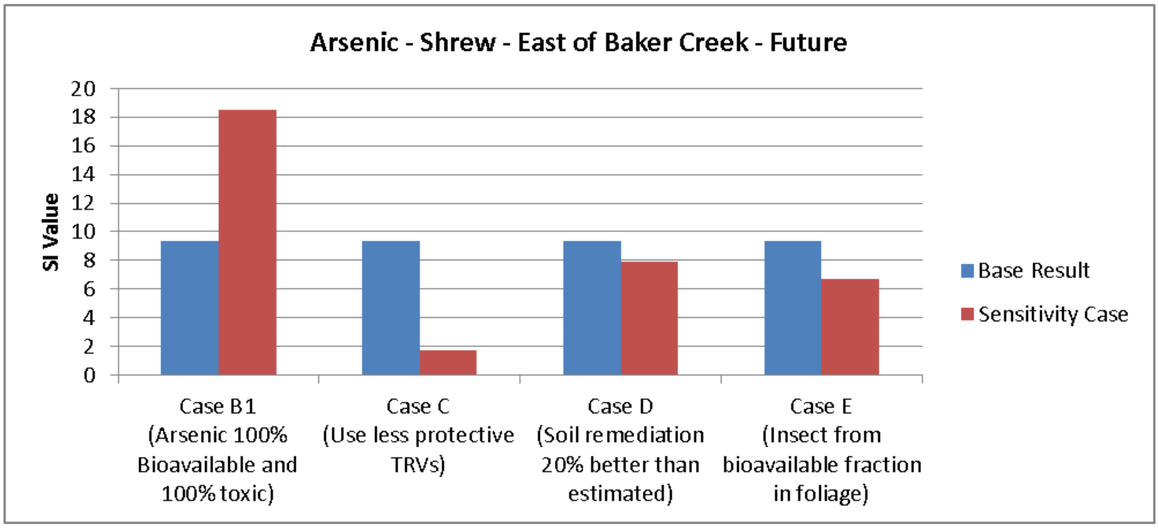

Figure 4.51 Sensitivity analysis results for hare in South Baker Creek – future – antimony

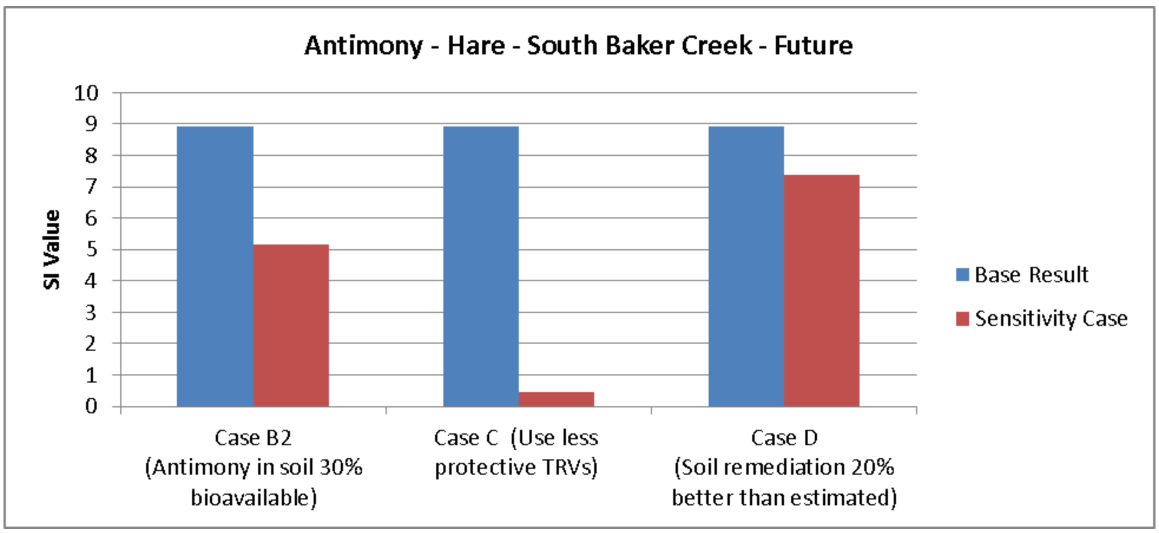


It was seen that changes to the water and sediment modelling (case A) and soil remediation (case D) are not expected to affect the conclusions of the ERA. Some receptors were seen to be sensitive to arsenic accessibility/toxicity assumptions (case B-1); however, the test assumptions are overly conservative and, as shown by the available data, not realistic.

Both reducing the antimony soil bioaccessibility to a number that is likely more realistic (case B-2) and changing the basis for terrestrial insect concentrations (case E) resulted in reduced SI values for some receptors; however, additional site data on bioaccessibility in COPC other than arsenic and insect concentrations would be needed prior to implementing more realistic assumptions such as these within the ERA.

The use of LOAELs for TRVs (case C) could potentially have a substantial impact on the calculated SI values. Despite this, however, there are still many receptors that have SI values above 1, indicating a potential for adverse effects. In addition, this approach may apply to all receptors, including species at risk such as the little brown bat and barn swallow.

Overall, the sensitivity analysis concluded that, while uncertainty in some factors may change predicted SI values for evaluated receptors, in every sensitivity case, SI values for many receptors and COPC remained well above the benchmark of 1. For this reason, uncertainty related to the examined factors is not expected to change the overall findings of the ERA. Additional information on the sensitivity analysis is provided in Appendix N.

4.6.3 Uncertainty Assessment

There are several areas of uncertainty in conducting a risk assessment due to the fact that assumptions have to be made throughout the assessment either due to data gaps, to environmental fate complexities, or in the generalization of characteristics related to behaviour and diet of ecological receptors. An accounting of the uncertainty is provided to be able to place a level of confidence in the results. The magnitude and type of uncertainty are important in determining the significance of the results. In recognition of these uncertainties, the ERA used cautious assumptions where possible to ensure that the potential for an adverse effect would not be underestimated. The major assumptions are outlined below.

The COPC concentrations used in the assessment were based on measured data, when available, from the aquatic and terrestrial environments from a variety of sampling programs. There is an extensive database of information on soil from the site. The use of reasonable maximum exposure concentrations, which were generally an upper estimate (95% UCLM) values of measured data result in reasonable yet conservative estimates of exposure. Even with the extensive amount of data available, there is still uncertainty with respect to appropriately representing the soil that would be accessible for ecological receptors. Golder (2015a) found that elevated arsenic concentrations are particularly pronounced in the outcrop terrain. Outcrop areas typically consist of bare, smooth rock surfaces with crevices, or hollows that collect soil. These crevices will limit the soil that is accessible to ecological receptors and, therefore, the assessment provided is conservative.

The assessment of aquatic resources in Baker Creek relied on information presented in a previous study (Golder 2013a). In this study, the uncertainty in parameters (chemistry, toxicity tests, benthic community evaluation) and in the structure of the assessment was evaluated. They found that uncertainties in these areas were unlikely to change the overall conclusions of the Baker Creek assessment.

Sediment COPC are somewhat mobile, as sediment moves within waterbodies and, over time, through sediment processes such as burial, sediment concentrations may decrease. Thus, the sediment concentrations as represented by the upper estimate (95% UCLM) may not represent the concentration of the COPC over the long term. Arsenic is known to be released from the sediments when there is not a lot of oxygen present and, in these cases, the arsenic becomes mobile and the concentrations in the sediment may increase. The assumption of long-term exposures to the upper estimate concentration for antimony is likely to have overestimated actual exposures. However, in the case of arsenic, it is difficult to determine whether it is an overestimate or an underestimate.

Concentrations of insects were required to assess the potential for effects on animals that use these as a source of food. In the absence of measured data, emergent aquatic insects were assumed to be related to benthic invertebrates since these insects begin their life cycle in the benthic community. For terrestrial insects, the concentration was assumed to be equal to measured vegetation. It is unclear how well this assumption represents concentrations of terrestrial insects. A sensitivity assessment was done in Section 4.6.2 that showed that this assumption is an important factor, especially for antimony, but is unlikely to affect the conclusions of the RA.

Many of the calculations, particularly for future conditions, used site-specific transfer factors (TFs) to estimate concentrations in the environment. There is always uncertainty in estimating concentrations; but the use of site-specific TFs is a reasonable approach and would be associated with less uncertainty than alternative methods such as the use of literature TFs.

Site-specific bioaccessibility and speciation data were not available for antimony, copper, manganese, and zinc; therefore, it was assumed that they were 100% available. In addition, the oral bioavailabilities of antimony, copper, manganese and zinc in soil, sediment and water were generally assumed to be equivalent to the highly bioavailable forms used in the toxicity studies. This assumption would lead to an overestimate of exposure. For arsenic, assumptions were made for the bioaccessibility in soil and sediments based on measured data for soils and sediments. In addition, for mammals and birds, it was assumed that the bioaccessibility was the same as the bioaccessibility measured in hare from the Yellowknife area based on a literature study (Koch et al. 2013). The assumption seemed reasonable; however, it is particularly uncertain for birds. As shown in Section 4.6.2, an assumption of 100% bioaccessibility was evaluated. This resulted in an increase in arsenic exposure; however, the conclusions were not affected.

The receptor characteristics are also a source of uncertainty, as receptors adjust and vary their diet according to the food sources available. The characteristics (e.g., body weight, food, soil consumption, etc.) of ecological receptors were obtained from the literature associated with animals in captivity and may not be fully representative of free-range animals in the wild. An underestimate of exposure might result from this, but there are other conservative assumptions that may compensate (i.e., time spent in area exposed to site contamination, sufficient food available at areas of highest contamination).

TRVs are obtained from reputable sources (e.g., ECCC, U.S. EPA); nonetheless, they are always associated with uncertainty due to the extrapolation of testing on lab species to field conditions as well as a range of receptors. There is uncertainty associated with the use of NOAEL and LOAEL values as TRVs, as these values are not directly related to biologically relevant thresholds and do not provide information about the actual magnitude of effects in the reported studies; however, they have widespread use in the risk assessment community, generally due to policy decisions (Allard et al. 2010). The TRVs used for wildlife in this assessment were NOAELs provided by in the FCSAP guidance (FCSAP 2015b).

The effect of multiple COPC on risk was not evaluated in this assessment. When dealing with more than one COPC, there is the potential interactions. There is insufficient information available to be able to evaluate these interactions.

Table 4.50 provides a summary of the uncertainties discussed above. It can be seen from the table that, in general, the uncertainties used in the assessment lead either to an overestimate of exposures or to no substantial change to the estimates, and, thus, the conclusions of the assessment remain unchanged.

Table 4.50 Summary of uncertainties in the ERA

Uncertainty	Overestimate	Possible Underestimate or Neutral Effect	Comment
Use of reasonable maximum exposure concentrations to characterize exposures.			The use of the 95% UCLM to represent exposures for most media may overestimate exposures by a factor up to two.
Use of upper bound concentrations of antimony in sediments.			Sediments are difficult to characterize accurately as even samples close to each other can be different. Generally sediment concentrations decrease over time. Much of the sediment data were collected over five years ago, thus may be overestimated. This is particularly relevant for antimony as arsenic is known to be maintained for a longer period of time in sediment due to geochemical processes. Overall, this is expected to be less than a factor of two.
Use of upper bound concentrations of arsenic in sediments.			
Limited data sets for some environmental media.			There are limited data available for some areas of the site (e.g. sediment in Reach 6) and in some media (e.g. aquatic plants). Conservative estimates were made but it is unknown the effect of this assumption.
Estimate emergent aquatic insects from benthic invertebrates.			In the absence of measured data, emergent aquatic insects were assumed to be related to benthic invertebrates since these insects begin their life cycle in the benthic community.
Estimate terrestrial insects from vegetation.			In the absence of measured data, terrestrial insects were assumed to be equal to terrestrial plants. Information on arsenic shows this may overestimate the exposure be a factor of two to 10.

Uncertainty	Overestimate	Possible Underestimate or Neutral Effect	Comment
Estimate concentrations using transfer factors.			Environmental concentrations were estimated using transfer factors that were derived based on site-specific information (small mammals, vegetation, fish, aquatic plants). There is a lot of variability in the data and the relationships are often weak, but this approach is associated with the least uncertainty of the options available.
Assumption of 100% bioaccessibility for antimony and manganese.			It is known that metals are not fully absorbed in the digestive system. This may overestimate exposure by a factor of two to 10.
Use of 50% arsenic bioaccessibility in hare to represent the bioaccessibility in wild game.			There is uncertainty in applying the bioaccessibility measurements in hare to other animals. A sensitivity analysis showed that different assumptions are not expected to change the conclusions.
Receptor characteristics for wildlife are unknown for site-specific conditions.			What animals eat and the amount of food is estimated based on available information. Consideration was given to local conditions but animals will change behavior depending on the habitat. They were assumed to reside entirely on the site, this is expected to be an overestimate for larger receptors such as fox and owl.
Use of NOAELs as the TRV.			Exceeding a no effects level does not necessarily mean that there will be an adverse effect. The use of lowest observed effect levels have been used to judge population-level effects. The use of NOAELs can overestimate risks by a factor between two and 10.
Interactions between COPC.			There may be synergism, potentiation, antagonism, or additivity of toxic effects. The use of multiple LOEs (e.g. benthic community surveys and toxicity tests) reduces the uncertainty in this knowledge gap.

5.0 INTEGRATED RESULTS/SUMMARY AND CONCLUSIONS

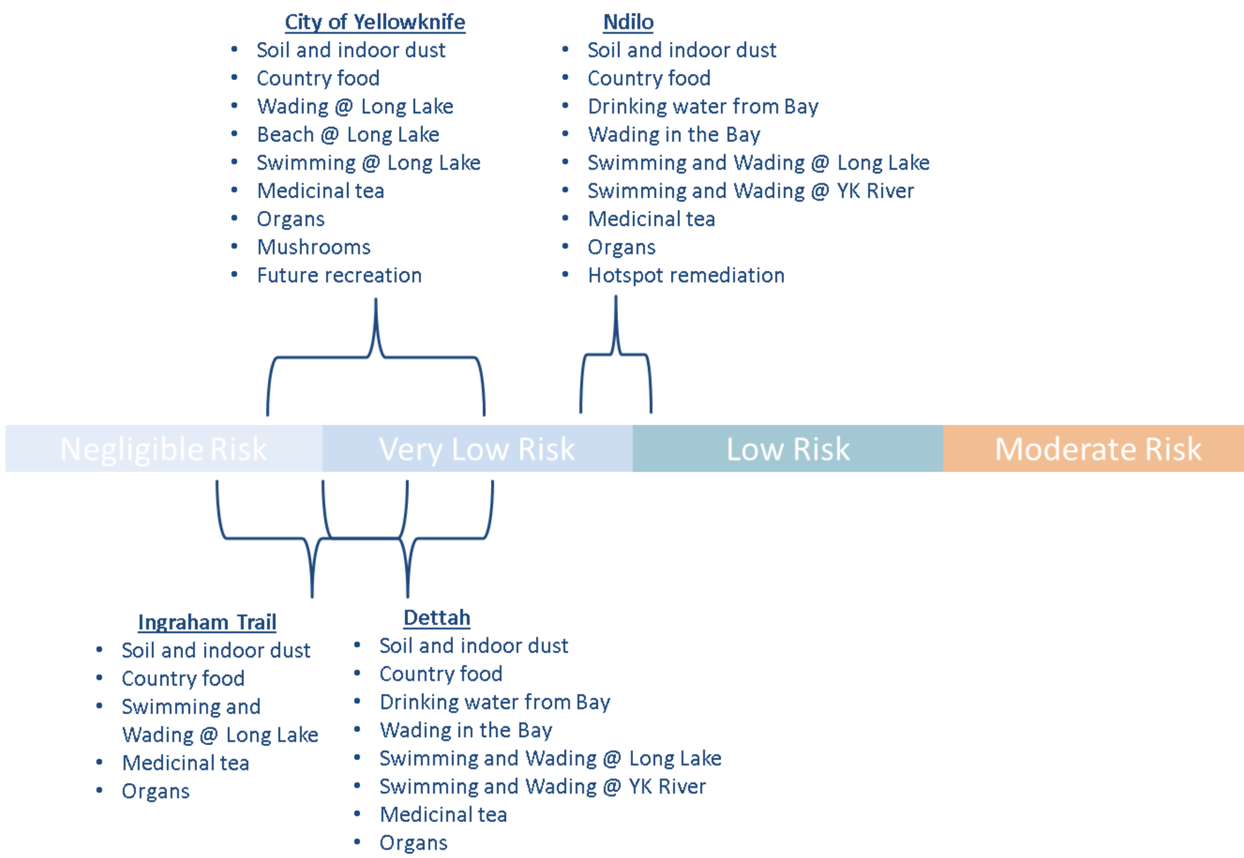
5.1 Human Health Risk Assessment

The following section provides a summary of the results for the HHRA, along with recommendations for future work.

The risks from COPC such as antimony, cadmium, lead, manganese, vanadium, and zinc were examined and found to be negligible now and in the future. The key concern from a health perspective is arsenic. Arsenic is considered to cause cancer and, therefore, the risk assessment evaluated the incremental, above-background risk from arsenic exposure in air, soils, indoor dust, water, sediment, and country foods in the area.

Figure 5.1 shows that the risks calculated are mainly within the negligible to very low risk range. These risks are equivalent to having dental x-rays or a chest x-ray. For Ndilo, the calculated risks are higher than for all other locations due to the higher arsenic concentrations in soil in the community due to historic contamination from when Giant Mine was in operation. The calculated risks are within the very low risk to the low risk range, which is equivalent to having x-rays or a CT scan. The risks for all other areas are similar and are dominated by soil and indoor dust exposure. Mushrooms within 10 km of Giant Mine have higher arsenic concentrations than background and results in risks in the very low range. Eating mushrooms collected from a distance greater than 25km from the Giant Mine results in negligible arsenic risk. The arsenic accumulating species *Tricholomatacae* collected within 10 km of the Giant Mine has very high arsenic concentrations and people should only eat small amounts of them.

Figure 5.1 Summary of estimated incremental lifetime cancer risks from arsenic



In terms of the population of the City of Yellowknife, which by the 2016 census was 19,569 people, about one additional person in the population in the Yellowknife area may develop cancer associated with arsenic exposure mostly associated with historical contamination across the Yellowknife area. It should be noted that the nature of risk assessment is to generally over-estimate actual exposures. Therefore, actual cancer incidence associated with the Giant Mine may be less than indicated here.

For the future, after the Giant Mine has been remediated, the risks will not be changed substantially, as the remedial actions at the Giant Mine will not alter the arsenic exposure across the Yellowknife area. At the former Townsite location, the remedial activities will reduce arsenic concentrations and, under a residential scenario (most restrictive land use), the risks are considered to be very low.

A number of sensitivity assessments were completed to examine the impacts of various assumptions used in the HHRA on the conclusions; the results indicated that the conclusion that there are low risks from arsenic exposure is considered valid.

Consideration of climate change indicated that, in the future, the risks from exposure to arsenic following remedial activities at the Giant Mine and under a potential climate change scenario will be within the low risk range.

Recommendations

There were uncertainties associated with some of the assumptions for the assessment; however, it is unlikely that additional data would change the conclusions of the risk assessment.

It is recommended to complete post-remediation sampling to confirm that concentrations in the future Townsite are similar to the values used in the risk assessment.

In addition, as the risks in Ndilo are higher than other areas and the result of historical activities when the Giant Mine was in operation, consideration should be given to developing a remedial action plan for soil clean-up in the community. The sensitivity analysis demonstrated that soil clean-up will reduce risks in Ndilo. Additional soil sampling should be carried out at Latham Island to determine whether the concentrations in the soil are similar to those assumed in the risk assessment.

Finally, it is recommended to use the results of the HHRA to inform the Health Effects Monitoring Program.

5.2 Ecological Risk Assessment

The following section provides a summary of the results for the ERA, along with recommendations for future work.

There are elevated levels of arsenic in the sediment of Yellowknife Bay, especially in Back Bay. Although there is remediation planned for sediment along the shore near the Giant Mine, this will have limited impact on the future sediment concentrations in Yellowknife Bay. However, the conditions in Yellowknife Bay are expected to improve over time, albeit slowly.

The ERA found that there are effects on aquatic biota, such as invertebrates and fish, in Baker Creek currently. There will be some improvement with remediation, but there is a large upstream load that will continue to result in elevated concentration of arsenic and antimony in Baker Creek. Dredging of sediments will destroy this habitat, but it will recover over time. However, the relocation of the treatment plant effluent to the mouth of

Baker Creek will change the flow, and Baker Creek may be dry during the summer months. The activities will affect how the creek will be used by fish and wildlife.

At the Giant Mine, the assessment determined that there is the potential for the smaller animals at the site to be affected by arsenic and antimony. This is a particular concern for those animals that consume insects. As animals can adapt to living in areas of high concentrations, the effects may not be as significant as predicted. The remediation will improve the situation, but adverse effects are still predicted in the future.

A number of sensitivity assessments were completed to examine the impact of various assumptions used in the ERA on the conclusions; the results indicated that the conclusions of the ERA would remain unchanged, including consideration of potential effects of climate change.

Recommendations

Based on the results of the ERA, the following activities are recommended:

- completion of biological studies to examine the health of vegetation at the site;
- collection of insect data to verify assessment assumptions; and
- examination of any differences in abundance and diversity of vegetation and mammals, particularly small mammals (shrews at terrestrial sites and muskrat in aquatic environments) by conducting biological surveys at the site compared to an appropriate reference area.

Significant changes are expected to habitats at the site due to remedial activities. It is recommended to update the wildlife surveys, including the presence of species at risk, after the remediation activities are completed. It is also recommended to complete post-remediation monitoring to determine whether any adverse effects are occurring in ecological species.

LIST OF APPENDICES

APPENDIX A

LIST OF AVAILABLE REPORTS AND STUDIES

TABLE OF CONTENTS

APPENDIX A: LIST OF AVAILABLE REPORTS

This Appendix provides a list of all the reports that were relied on in the risk assessment report. Some of the reports had data that were extracted and used in the calculations and others had information that was considered in the fate and transport modelling or in weight–of–evidence analysis for the ecological risk assessment.

A.1 List of Reports Consulted for Characterization

The reports that have been consulted related to the aquatic environment are as follows:

- *City of Yellowknife drinking water data.*
- *Contango 2016 Wetland Field Investigation Report for Giant Mine. November.*
- *Cott et al. 2015 Arsenic and mercury in lake whitefish and burbot near the abandoned Giant Mine on Great Slave Lake. (contains data from 2010, 2012).*
- *Deton'Cho/Nuna Joint Venture MMER data from 2008 – 2009.*
- *Deton'Cho/Nuna Joint Venture 2014 Giant Mine remediation project – Surveillance Network Program (SNP) 2014 annual report.*
- *Deton'Cho/Nuna Joint Venture 2014 Giant Mine Remediation Project - Surveillance Network Program 2014 Annual Report.*
- *Deton'Cho/Nuna Joint Venture 2015 SNP report for December 2015.*
- *Deton'Cho/Nuna Joint Venture 2016 SNP report for February 2016.*
- *ECCC 2015 Metal concentrations in sediments and surface waters adjacent to Ndilo and Dettah in Yellowknife Bay. (contains data from 2014).*
- *ECCC 2016 Metal concentrations in sediments and surface waters adjacent to Ndilo and Dettah in Yellowknife Bay. Update from 2015. (contains data from 2015).*
- *Galloway et al. 2015 Geochemistry of lakes across ecozones in the Northwest Territories and implications for the distribution of arsenic in the Yellowknife Region. (contains data from 2012 and 2014).*

- *GNWT 2016 NWT Open File 2015-06 The Concentration of Arsenic in Lake Waters of the Yellowknife Area.*
- *Golder MMER data from 2011 – 2015 (Back Bay data).*
- *Golder MMER data from 2011 – 2015.*
- *Golder 2011 INAC Baker Creek grayling project.*
- *Golder 2012 Technical Memo: Baseline Data Collection for Snow Depth, Ice Thickness, and Water Quality for Hydrodynamic Modelling of Yellowknife Bay, Great Slave Lake, NWT.*
- *Golder MMER data from 2012.*
- *Golder 2013 2011 Baker Creek assessment, Giant Mine, Yellowknife, NWT. (contains data from 2010 and 2011).*
- *Golder 2015 Assessment of arsenic in sediments/surface water in Upper Baker Creek, Giant Mine lease and adjacent lands. (contains data from 2014).*
- *Golder 2015 Water Quality Sampling Program - Baker Creek.*
- *Golder 2016 2015 Runoff Sampling Program - Giant Mine.*
- *Golder 2016 Giant Mine Data Report – Human Health and Ecological Risk Assessment Data Gaps.*
- *Golder 2017 Task 5 Draft Report- Remedial Options and Scenarios Report, Baker Creek and Baker Pond, Giant Mine Project, NT.*
- *Houben 2016 Factors Affecting Elevated Arsenic and Methyl Mercury Concentrations in Small Shield Lakes Surrounding Gold Mines near the Yellowknife NT Region.*
- *Jacques Whitford 2006 Sediment investigation of Baker Creek, Giant Mine, Yellowknife, NT. (contains data from 2005).*
- *Palmer 2016 Back Bay Sediment and Surface Water data.*

- *Schuh and Jamieson 2015 Poster – Spatial variations in arsenic geochemistry in sediments and their associated porewaters from lakes in the Yellowknife region.*
- *SENES 2006 Tier 2 risk assessment – Giant Mine remediation plan.*
- *Stantec 2014 Analysis of contaminants in tissues of fish captured in the Yellowknife Bay area, NT Final Report. (contains data from 2010, 2011, 2012, 2013).*
- *Stantec 2014 Aquatic data collection in Lower Martin Lake, Upper Baker Creek and Trapper Creek. (contains data from 2013).*
- *Stantec 2014 Technical data report for the Yellowknife Bay baseline studies Volume 1: Aquatics final report. (contains data from 2004, 2012, 2013).*
- *Stantec 2015 Sediment and porewater study of the Baker Creek Outlet, Draft interpretive report. (contains data from 2015).*
- *Stantec 2015 Technical data report for aquatics and fisheries studies in Gar Lake, Trapper Lake, Upper Shot Lake and Lower Shot Lake. (contains data from 2014).*

The reports consulted for the terrestrial environment were as follows:

- *AECOM 2016 Contaminated Soils Task 2C: North Tailings Pond - Preliminary Results for 2016 Field Investigation.*
- *Contango 2016 Wetland Field Investigation Report for Giant Mine. November.*
- *ESG 2001 Arsenic levels in the Yellowknife Area: Distinguishing between natural and anthropogenic inputs.*
- *GNWT 2015 Contaminant Survey of Sahtu and South Slave Moose, Sahtu Mountain Caribou and Barren–Ground Caribou: A Plain Language Summary. (contains moose and caribou liver and kidney data from 2010 to 2015).*
- *Golder 2014 Revised letter report on shallow soil sampling programs. (contains data from 2013).*
- *Golder 2015 Assessment of regional soil quality, Giant Mine, Yellowknife, NT. (contains data from 2014).*

- *Golder 2016 Arsenic characterization – disturbed Areas, Giant Mine, Yellowknife, NT. (contains data from 2015).*

- *Golder 2016 Arsenic characterization – undisturbed areas, Giant Mine, Yellowknife, NT. (contains data from 2014, 2015).*

- *Golder 2016 Roaster complex soil and vegetation sampling Giant Mine, Yellowknife, NT. (contains data from 2015 for soils, aster, fireweed, grasses/forbs, foxtail barley, goldenrod, Labrador tea/black spruce (50/50), red–osier dogwood, wheat grass, white spruce/shrub species (60/40), wild red raspberry, and willow from the Giant Mine site and two background locations).*

- *Golder 2016 Giant Mine Data Report – Human Health and Ecological Risk Assessment Data Gaps.*

- *Golder 2016 Task 2A-Potential Remedial Strategy - Town Site and Shoreline Lands.*

- *Golder 2016 Preliminary Findings Memo - Task 2B - Proposed Core Industrial Area.*

- *Hough 2001 Characterization of arsenic in a short terrestrial food chain Yellowknife, Northwest Territories. (contains data for deer mice from the Giant Mine Site, Con Mine Site, and Yellowknife from 2000).*

- *Kerr 2001 Till geochemistry, Yellowknife area, NWT. Natural Resources Canada, Ottawa. http://geochem.nrcan.gc.ca/cdogs/content/svy/svy210026_e.htm.*

- *Koch et al. 2005 Arsenic speciation in terrestrial birds from Yellowknife, Northwest Territories, Canada: The unexpected finding of arsenobetaine.*

- *Koch et al. 2013 Bioaccessibility and speciation of arsenic in country foods from contaminated sites in Canada. (contains data from 2000, 2004, and 2010 for mushrooms, cranberries, and Labrador tea from a contaminated area in Yellowknife; contains data for hare from Yellowknife from 2000 and 2010).*

- *NCPP 1999 Risk Characterization of Arsenic Exposure to Berries in Akaitcho Territory.*

- *Obst 2014 Heavy metals in soil and edible mushrooms in the North Slave Region, Northwest Territories, Canada, and assessment of the potential human health risk from the consumption of edible wild mushrooms. (contains data from 1997 to 2009 for edible mushrooms from the Giant Mine site, the Con Mine site, City of Yellowknife, and a background location).*

- *Ollson 2000 Arsenic Contamination of the Terrestrial and Freshwater Environmnet Impacted by Gold Mining Operations Yellowknife, N.W.T.*

- *Queen's (Bromstad) The characterization, persistence, and bioaccessibility of roaster–derived arsenic in surface soils at Giant Mine, Yellowknife, NT. (Thesis) (contains data from 2010).*

- *Queen's (Wrye) Distinguishing between natural and anthropogenic sources of arsenic in soils from the Giant Mine, Northwest Territories and the North Brookfield Mine, Nova Scotia. (contains data from 2007).*

- *Ripley 2012 Yellowknife centralized composting pilot project final report. (contains data on two batches of finished compost from 2011 and 2012).*

- *RMC 2001 Characterization of the potential human health risk from consumption of garden produce in Yellowknife, NWT. (Health Risk from Garden Produce – RMC ESG 2001) (contains data from 2001).*

- *RMC 2013 Arsenic in Ndilo, NT: 2012 sampling. (contains data from 2012 for unidentified plant species in Ndilo).*

A.3 Summary of Previous Ecological Risk Assessments

There are two different ecological assessments that are considered as the foundation for the development of the Problem Formulation. These studies, summarized in the following sections, include:

- Ecological Risk Assessment for Giant Mine (SENES 2006)
- Assessment of Aquatic Resources in Baker Creek (Golder 2013)

A.3.1 Previous Ecological Risk Assessment (SENES 2006)

A Tier 2 Risk Assessment of the Giant Mine site was conducted previously (SENES 2006). The assessment was used to support the evaluation of proposed remedial options for the contamination on the surface of the Giant Mine site as well as possible future releases of arsenic from the underground workings. In addition, the results of the risk assessment were used within the Environmental Assessment Report that was submitted to the Mackenzie Land and Water Board. The summary in this section focusses on the ecological risk assessment component of the Tier 2 Risk Assessment.

The mandate of the assessment was only to evaluate exposure to arsenic; thus this is the only COPC that was considered in the assessment.

Aquatic receptors were selected to represent a typical food chain that would be found in Baker Creek, Back Bay and Yellowknife Bay and included:

Primary Producers	• Aquatic plants and benthic algae
Primary Consumers	• Benthic invertebrates
Secondary consumers	• Bottom feeding fish (e.g., lake whitefish and sucker)
Tertiary consumers	• Predatory fish (e.g., northern pike, lake trout)

The receptors evaluated in the terrestrial environment included:

Herbivores	• Barren ground caribou • Moose • Muskrat • Snowshoe hare • Spruce grouse

Omnivores	• Black bear
	• Waterfowl as represented by:
	  o Mallard
	  o Merganser
	  o Scaup

Carnivores	• Mink • Wolf

Exposure pathways considered were direct contact with COPC in surface water and sediment and ingestion of dietary items with elevated COPC concentration. These pathways were linked to either the aquatic environment of Baker Creek, Back Bay and Yellowknife Bay or the terrestrial environment including the Giant Mine site and lower Baker Creek watershed.

The assessment considered a remediation case which involved predictive modelling in the aquatic environment to develop future arsenic concentrations in water and sediment. Transfer factors were used to develop concentrations in other environmental compartments. For the terrestrial environment it was assumed that the entire site was remediated to GNWT industrial criteria and transfer factors were used to derive concentrations in the other terrestrial components. It was assumed that the sediments in Baker Creek would not be dredged.

Screening index values were calculated that compared the exposure to a toxicity reference value (TRV). This was the primary line of evidence in the ERA; however, other information (e.g. fish surveys, muskrat surveys) was also considered in the discussion of overall results.

It was found that no adverse effects are expected on the aquatic plants and fish of Back Bay and Yellowknife Bay after remediation. There was some potential for fish to be impacted within Baker Creek but more biological sampling was recommended to allow for a weight of evidence approach. Further studies of Baker Creek sediments were also recommended to whether historical arsenic contamination in Baker Creek sediment caused a reduction in benthic community diversity. The diversity of benthic communities in parts of Back Bay and North Yellowknife Bay may also be affected by existing levels but it was noted that this situation will gradually improve as sediments with elevated arsenic levels are buried over time and covered with cleaner material.

The results of the risk assessment for terrestrial receptors showed that, with the exception of hare and mammals that have a diet in the aquatic environment of Baker Creek (mink and muskrat), no adverse effects were expected (including bear, caribou, grouse and wolf). Likewise, the arsenic intakes predicted for the three duck species were well below the TRVs. Cautious assumptions were adopted (e.g. time spent on–site).

The intake of terrestrial vegetation was found to be the significant pathway for the hare. For the muskrat and mink the arsenic exposure was primarily from water, sediment and aquatic plants. A field investigation for muskrat was undertaken on Baker Creek to support the assessment. Based on the measured tissue levels and field evidence from the biological survey which indicates that there are active dens that support a substantial population of muskrat on Baker Creek, it is unlikely that the presence of arsenic in the sediments of Baker Creek is causing serious adverse effects on populations of small terrestrial mammals that have a significant aquatic based diet.

A.3.2 Assessment of Aquatic Resources in Baker Creek

Golder completed an assessment of the aquatic community in Baker Creek (Golder 2013). The overall objective of the report was to support decision–making activities with respect to the remediation options for Baker Creek.

The COPCs included in the assessment were aluminum, antimony, arsenic, beryllium, cadmium, chloride, chromium, copper, cyanide, iron, lead, manganese, mercury, nickel, nitrate, selenium, silver thallium, and zinc.

Aquatic receptors were selected to provide a representation for each ecosystem component in Baker Creek including:

- Phytoplankton community
- Zooplankton
- Benthic invertebrates; and,
- Fish: small–bodied fish (such as slimy sculpin and ninespine stickleback) and large–bodied fish (such as northern pike and arctic grayling)

Exposure pathways considered were direct contact with COPC in surface water and sediment and ingestion of dietary items with elevated COPC concentration.

The overall assessment endpoint was the maintenance of productive and diverse populations and communities of aquatic biota (both invertebrates and fish) in Baker Creek that were not adversely affected by COPCs in water, sediments or their tissues.

The study considered the available data (e.g. water quality) in addition to information that was collected specifically to support the study including:

- Additional surface water and sediment samples
- Benthic invertebrate sampling (with enumeration, taxonomy and chemical analysis)
- Fish tissue samples
- Fish community surveys in Trapper Lake and Lower Martin Lake

Baker Creek was divided into 7 reaches, namely Reaches 0 to 6 as well as Upper Baker Creek and Trapper Creek which is an upstream tributary to Baker Creek. A weight of evidence approach was used to integrate the data from Baker Creek into a determination as to whether there were unacceptable adverse ecological effects. This approach incorporated lines of evidence such as sediment chemistry, benthic community structure, and surface water and sediment toxicity test results. Fish community and chemistry were considered separately as they were not available for all reaches and fish were expected to move throughout the creek.

Receptor	Assessment Endpoint	Measurement Endpoints (Lines of Evidence)
Benthic invertebrate community	Maintenance of the health and ecological integrity of the infaunal benthic invertebrate community	• Compare sediment chemistry to CCME guidelines. Determine bioavailability • Sediment toxicity tests • Surface water toxicity tests • Benthic invertebrate community
Water column organisms	Maintenance of the health and ecological integrity of water column organisms that form part of the fish food chain	• Compare water chemistry to CCME guidelines and other benchmarks. • Surface water toxicity tests
Fish community	Maintenance of the health and ecological integrity of the fish populations	• Compare water chemistry to CCME guidelines and other benchmarks. • Compare tissue chemistry to guidelines and other relevant benchmarks

It was found that approximately 30% of the locations examined were classified as having significant adverse effects, 45% of the locations had potential adverse effects and 25% of the locations had negligible adverse effects. There was no gradient of potential effects and toxicity "hot spots" were located throughout Baker Creek. It was found that benthic invertebrates were found at all locations, even those with elevated concentrations; thus recolonization of sediments by benthic invertebrates is occurring. The elevated concentrations in the sediment are available to fish and other organisms in Baker Creek.

This is a key study that will be relied upon extensively in ERA to assess current conditions for aquatic biota in Baker Creek and provide additional information on the lines of evidence within the ecological risk assessment.

APPENDIX B

SUMMARY OF AVAILABLE DATA

TABLE OF CONTENTS

LIST OF ATTACHMENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX B: SUMMARY OF AVAILABLE DATA

A summary of available data for each of the media considered in the human health and ecological risk assessment is presented below along with maps of the sampling locations. The full dataset containing all samples and all sample locations for aquatic and terrestrial media is provided in Appendix O. Additionally, a summary of the results of voluntary sampling program which took place from September 2016 to January 2017 is provided below.

The Giant Mine Remediation Program (GMRP) has conducted numerous studies at the Giant Mine in order to get a good understanding of the conditions of the soils, sediments and surface water on and around the site. These studies are all being considered in the risk assessment as well as in the development of the remedial action plans for the Giant Mine.

Several off-site sampling programs have been conducted as studies for the Cumulative Impact Monitoring Program (CIMP), the Yellowknives Dene First Nation (YKDFN) or the Government of the Northwest Territories (GNWT). The historic soil samples focused on arsenic whereas the current programs analyzed a wider suite of constituents of potential concern (COPC).

B.1 Air

Ambient air quality is monitored year-round under the Giant Mine Ambient Air Monitoring Program at the following community locations:

- Marina Station – Great Slave Sailing Club, near the Giant Mine public dock (Station YCC).
- Ndilo Station – Central Ndilo (Station NDL).
- Yellowknife Station – Downtown Yellowknife City (Station NAPS).

Additional atmospheric monitoring programs record conditions at six fence line stations as well as at a number of stations on the Giant Mine property.

Air quality data collected over the 2015 calendar year at the community, fence line and Giant Mine stations were used to represent current conditions. Sample locations are presented in Figure B.1 and a summary of the data is presented in Table B.1.

B.2 Soil

B.2.1 Giant Mine

There have been a number of soil studies (1999 through 2016) carried out at the Giant Mine which have focussed on the disturbed and undisturbed soils and there are over 300 recent soil samples collected at the Giant Mine. The following studies were included in the characterization of Giant Mine soils:

- *AECOM* (2016) *Contaminated soils task 2C: North Tailings pond - historical tailings release preliminary results for 2016 field investigation. Memorandum to D. Hango, Public Services and Procurement Canada, October 7 2016.*

- *Contango* (2016) *Wetland field investigation report for Giant Mine. Document # 003_1116_04A prepared for Golder Associates, November.*

- *ESG* (2001) *Arsenic levels in the Yellowknife Area: Distinguishing between natural and anthropogenic inputs.*

- *Golder* (2014) *Revised letter report on shallow soil sampling programs Giant Mine, Yellowknife, Northwest Territories. Project No. 13-1377-0147, February.*

- *Golder* (2016a) *Arsenic Characterization Disturbed Areas Giant Mine, Yellowknife, NT.*

- *Golder* (2016b) *Draft report on arsenic characterization undisturbed areas Giant Mine, Yellowknife, NT.*

- *Golder* (2016c) *Task 2A - potential remedial strategy Town Site and shoreline lands, Giant Mine project, NWT. Report number 13-1377-0044, submitted to Public Works and Government Services Canada. Draft report, September.*

- *Golder* (2016d) *Preliminary findings memo - Task 2B: Development of institutional/engineering control strategy proposed core industrial area, Giant Mine project, NWT. Technical memorandum to D. Hango, Public Services and Procurement Canada, October 7 2016.*

- *Golder* (2016e) *Giant Mine data report - human health and ecological risk assessment data gaps.*

- *Golder* (2016f) *Roaster Complex soil and vegetation sampling Giant Mine, Yellowknife, NT.*

- *Stantec* (2014a) *Analysis of contaminants in tissues of fish captured in the Yellowknife Bay area, NT. Task authorization 700263428, prepared for Public Works and Government Services Canada. Final report, March.*

- *Queens Bromstad* (2011) *The characterization, persistence and bioaccessibility of roaster-derived arsenic in surface soils at Giant mine Yellowknife NT. Master of Science thesis, Department of Geological Sciences and Geological Engineering, Queen's University.*

- *Queens Wrye* (2008) *Distinguishing between natural and anthropogenic sources of arsenic in soils from the Giant Mine, Northwest Territories and the North Brookfield Mine, Nova Scotia. Queen's University.*

Of the samples used to characterize Giant Mine soils, 58 were obtained as a part of the Golder (2016e) Giant Mine Data Gaps Report in support of the human health and ecological risk assessment (see ATTACHMENT B.1). Sample locations are presented in Figure B.2 and a summary of the data is presented in Table B.2. As seen in the figure, there are an adequate number of samples to characterize the soils at the Giant Mine.

B.2.2 Former Townsite

There have been four soil studies in recent years collected in 2007, 2014, 2016 carried out at the former Townsite (Wrye 2008; Golder 2015a, 2016c, 2016e). More than 90 soil samples are available and are considered to be adequate to characterize exposure at the former Townsite. Of the samples used to characterize the former Townsite soils, 4 were obtained as a part of the Golder (2016e) Giant Mine Data Gaps Report in support of the human health risk assessment (see ATTACHMENT B.1). Sample locations are presented in Figure B.3 and a summary of the data is presented in Table B.3.

Figure B.3 Soil sampling locations on the Former Giant Townsite

Table B.3 Summary of soil concentrations on the former Giant Townsite

Constituent	Unit	N	N<MDL	Min	Max	Average	StDev

B.2.3 City of Yellowknife

There have been six soil studies conducted in the City of Yellowknife (ESG 2000; Kerr 2001; NCP 1999; Ollson 2000; Obst 2014; SENES 2006). The majority of samples were collected at surficial soil depths and were sufficient for characterizing City of Yellowknife soils. Sample locations are presented in Figure B.4 and a summary of the data is presented in Table B.4. It should be noted that the sample locations presented on the figure only represent locations where co-ordinates are available. As seen from Table B.4 there are over 250 soil samples for arsenic in the City of Yellowknife which are considered to be adequate to characterize exposure in the City of Yellowknife.

Figure B.4 Soil sampling locations for the City of Yellowknife

Table B.4 Summary of soil concentrations from City of Yellowknife

Constituent	Unit	N	N<MDL	Min	Max	Average	StDev

Zirconium	mg/kg	2	1	100	290	195	134

B.2.4 Ndilo

For the community of Ndilo, there are three studies that contains soil sampling in the first 10 cm and they are listed below:

- *ESG* (2001)*, Arsenic Levels in the Yellowknife Area: Distinguishing Between Natural and Anthropogenic Inputs.*
- *RMC* (2013)*, Arsenic in Ndilo, NT: 2012 sampling. (contains data from 2012).*
- *SENES ,* (2006) *Tier 2 Risk Assessment Giant Mine Remediation.*

There are 25 surficial samples collected in this study. There was another study conducted in 2014 by Stantec, which collected 90 samples at depths ranging from 10 to 30 cm to represent tilled material. The report is as follows:

- *Stantec* (2014)*, Characterization of arsenic concentrations in soils in Ndilo, Northwest Territories.*

Over 100 samples are available for arsenic as well as antimony. Soil sampling locations are presented in Figure B.5 and a summary of the data is presented in Table B.5. From the figure it can be seen that the soils samples are adequate enough to characterize the soils in Ndilo. It should be noted that in the development of EPCs for Ndilo, only surficial soil samples from the first 10 cm were used.

Figure B.5 Soil sampling locations for Ndilo

Table B.5 Summary of soil concentrations from Ndilo

Constituent	Unit	N	N<MDL	Min	Max	Average	StDev

Zirconium	mg/kg	90	4	0.25	18	3.5	3.3

B.2.5 Latham Island

There have been very little data collected in the community on Latham Island with only two samples available for most constituents. There were four studies available that contained information on soil sampling (ESG 2000; NCP 1999; Ollson 2000; SENES 2006). In the ESG (2000) and Ollson (2000) studies, only 10 constituents were analysed and each contributed one sample per study. The NCP (1999) and SENES (2006) contributed one and four samples with arsenic concentrations, respectively. Sample locations are presented in Figure B.6 and a summary of the data is presented in Table B.6. Sample locations from NCP (1999) and SENES (2006) were unavailable. These samples were combined with samples from Ndilo to represent the same geographical area and used in the HHRA.

Figure B.6 Soil sampling locations for Latham Island

Table B.6 Summary of soil concentrations from Latham Island

Constituent	Unit	N	N<MDL	Min	Max	Average	StDev
Antimony	mg/kg	2	0	0.37	1.9	1.1	1.1
Arsenic	mg/kg	7	0	5.9	50	22	16

Zinc	mg/kg	2	0	8.8	334	171	230

B.2.6 Ingraham Trail

There have been very little data collected in the community on Ingraham Trail with fewer than 10 samples available for most constituents. There were three studies available that contained information on soil sampling (ESG 2001; Kerr 2000; Obst 2014). All samples were obtained at surficial depths except for one from Kerr (2000). Sample locations are presented in

Figure B.7 and a summary of the data is presented in Table B.7. These are the only data available and therefore were used in the assessment. There are 12 samples for arsenic, which is the main COPC identified.

Figure B.7 Soil sampling locations for Ingraham Trail

B.2.7 Fred Henne Campground

The Fred Henne Campground was identified as an area of concern for people from Yellowknife who go there to camp. Thus this was recognized as a data gap; as such, 11 samples were collected in 2016 by Golder (2016e) to support the data gaps analysis as described in ATTACHMENT B.1. An additional sample from Ollson (2000) was also used to characterize soils. The samples were collected from areas where people are known to use tents. Sample locations are presented in Figure B.8 and a summary of the data is presented in Table B.8.

Figure B.8 Soil sampling locations for Fred Henne Campground

B.2.8 Dettah

There have been very little data collected in the community of Dettah. There were two studies that contained information on soil sampling:

- *ESG* (2001)*, Arsenic Levels in the Yellowknife Area: Distinguishing Between Natural and Anthropogenic Inputs.*
- *NCP* (1999)*, Risk Characterization of Arsenic Exposure to Berries in Akaitcho Territory.*

In the ESG (2001) study, only 10 constituents were analysed in a total of eight samples. The NCP (1999) contributed one sample analysed for arsenic. Sample locations are presented in Figure B.9 and a summary of the data is presented in Table B.9. These are the only data available and therefore were used in the assessment. It is acknowledged that adequate coverage has not been provided in Dettah but it is the only data available.

Figure B.9 Soil sampling locations for Dettah

Table B.9 Summary of soil concentrations from Dettah

Constituent	Unit	N	N<MDL	Min	Max	Average	StDev
Antimony	mg/kg	8	0	0.17	6.2	2.4	2.4

Zinc	mg/kg	8	0	8.2	37	24	10

B.3 Surface Water

Surface water samples are available from various areas around Yellowknife Bay, Baker Creek, and the Upper Baker Creek Watershed.

B.3.1 Baker Creek

From all the studies on Baker Creek, it can be seen that there are a large amount of surface water samples available for Baker Creek (> 300 samples). The samples were obtained from 10 studies (Golder 2013a, 2013b, Stantec 2014b, 2014c, Golder 2015b, 2015c, 2016g, 2016h, 2016i; Contango 2016) and collected from 2011 through 2016. Sample locations are presented in Figure B.10 and a summary of the data is presented in Table B.10. There are sufficient surface water samples available to adequately characterize Baker Creek.

Figure B.10 Surface water sampling locations in Baker Creek

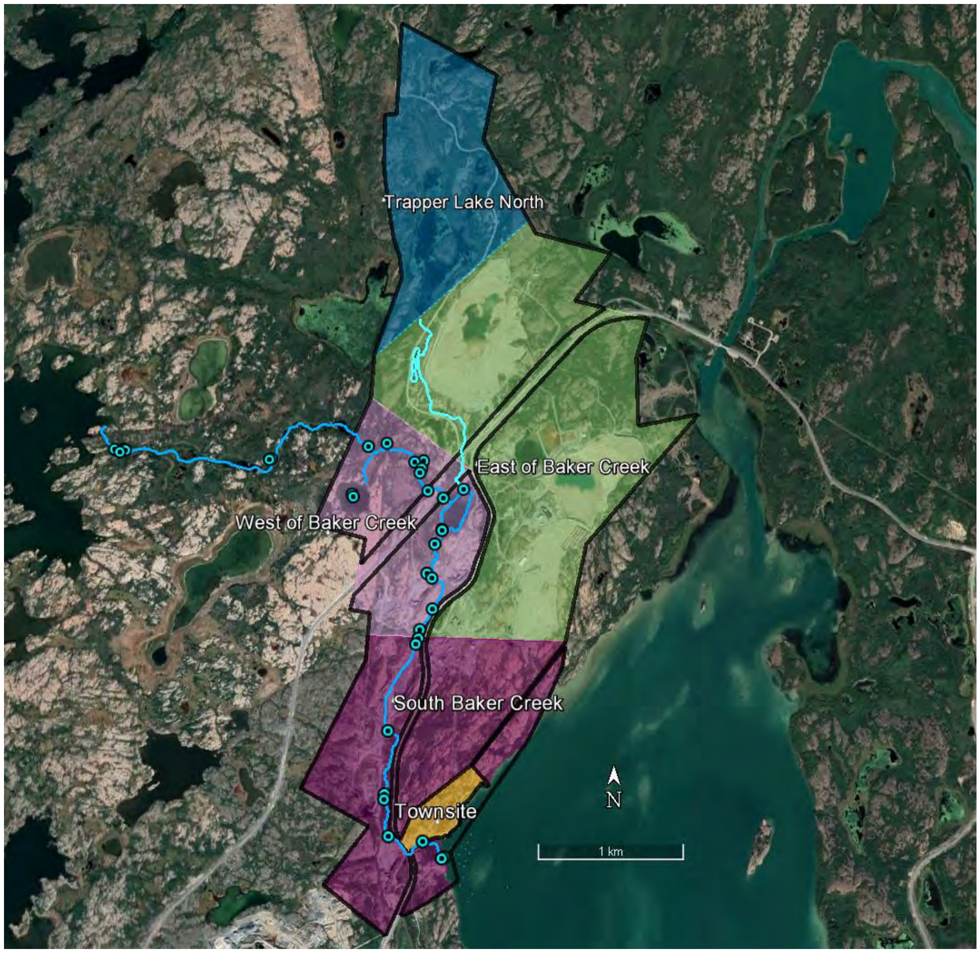

Table B.10 Summary of surface water concentrations in Baker Creek

B.3.2 Yellowknife Bay

For the purposes of the risk assessment, Yellowknife Bay was subdivided into three areas: (1) Back Bay which receives inputs from Baker Creek, (2) north Yellowknife Bay which interacts with Back Bay, and (3) south Yellowknife Bay. Yellowknife Bay (Back Bay, North Yellowknife Bay and South Yellowknife Bay) has been well characterized, with > 150 samples collected in recent years (2012 through 2016) for most constituents. Surface water samples were obtained from five studies (Golder 2012; Stantec 2014c; Palmer 2016; Contango 2016; Chételat 2016). Sample locations are presented in Figure B.11 and a summary of the data is presented in Table B.11.

B.3.3 Long Lake

There were also concerns raised about children wading and playing in the shallow sediments in Long Lake. This was identified as a data gap and in 2016 Golder (2016e) collected samples to address this data gap. Water samples were collected from the beach area, day use area, and from the marina (see ATTACHMENT B.1). Sample locations are presented in Figure B.12 and a summary of the data is presented in Table B.12.

B.3.4 Municipal Drinking Water

Municipal drinking water samples were obtained from wells (Wet Well PH#1 Station and Bay Well Station), residents, Yellowknife River, and treated locations (PH#1 Treated Water) from years 2002 until 2016. The data are summarized in Table B.13.

Table B.13 Summary of municipal drinking water concentrations

B.4 Sediment

There have been a number of sediment studies in recent years that have been carried out in Yellowknife Bay and in Baker Creek. For the purposes of the human health risk assessment sediments close to the shore are the focus of the as people could be exposed to COPC while wading along the shoreline. For the ecological risk assessment, shoreline sediments and sediments found at deeper depths were considered. Only sediment data from samples collected from the top 10 cm were selected as it benthic invertebrates are unlikely to colonize the deeper sediments.

B.4.1 Baker Creek

A total of 11 sediment sampling programs between 2005 and 2016 were available to characterize Baker Creek sediments (Galloway et al. 2015; Golder 2013a; 2013b; Golder 2015b; Golder 2016b; 2016e; Golder 2017; Jacques Whitford 2006; Stantec 2012; 2014a; 2015). There are more than three hundred sediment samples collected across Baker Creek. Therefore, the creek is adequately characterized. Of the samples used to characterize the sediments in Baker Creek, 29 were obtained as a part of the Golder (2016e) Giant Mine Data Gaps Report in support of the ecological risk assessment (see ATTACHMENT B.1). Sample locations are presented in Figure B.13 and a summary of the data is presented in Table B.14.

B.4.2 Yellowknife Bay

The various areas of Yellowknife Bay (Back Bay, North Yellowknife Bay and South Yellowknife Bay) have been well characterized, with > 150 samples collected in recent years (2004 through 2016) for most constituents. A total of five sediment sampling programs between 2005 and 2016 were available to characterize Yellowknife Bay sediment (ECCC 2015a, 2015b; Golder 2016e; Palmer 2016; Stantec 2014c). The majority of samples (approximately 150) were collected at surficial depths. From a human health perspective, shallow sediments at Ndilo and Dettah were used to characterize exposure for a wading scenario. Additionally, Mike Palmer collected some samples in Back Bay where concerns were raised about children wading in the areas near docks. There are about 20 sediment samples in Yellowknife Bay available to characterize shallow sediments. Over 60 sediment samples have been used to characterize exposure in Yellowknife Bay from an ecological perspective. Sample locations are presented in Figure B.14. A summary of the data considered for the human health assessment is presented in Table B.15 while one for the ecological assessment is presented in Table B.16.

B.4.3 Long Lake

There were also concerns raised about children wading and playing in the shallow sediments in Long Lake. This was identified as a data gap and, as such, in 2016 Golder (2016e) collected samples to address this data gap. Sediment samples were collected from the beach area, day use area, and from the boat launch (see ATTACHMENT B.1). Sample locations are presented in Figure B.15 and a summary of the data is presented in Table B.17.

B.5 Vegetation on Giant Mine

B.5.1 Aquatic Vegetation

Two aquatic plant sampling programs were conducted on the Giant Mine in 2016 with more than 20 samples per constituent (Contango 2016; Golder 2016e). Cattails and various species of sedges were collected for analysis to represent aquatic plants on the Giant Mine. Of the samples used to characterize the aquatic plants in Baker Creek, 22 were obtained as a part of the Golder (2016e) Giant Mine Data gaps report in support of the human health risk assessment (see ATTACHMENT B.1). Sample locations are presented in Figure B.16 and a summary of the data is presented in Table B.18.

B.5.2 Terrestrial Vegetation

Four terrestrial wild plant sampling programs were conducted on the Giant Mine in 2016 with more than 90 samples (Contango 2016; Golder 2016f, 2016e; Stantec 2014d). Foliage, fruits and flowers, lichen and moss, and woody vegetation samples were collected for analysis to represent terrestrial wild plants on the Giant Mine. Of the samples used to characterize the terrestrial plants on Giant Mine, 87 were obtained as a part of the Golder (2016e) Giant Mine Data Gaps Report in support of the human health and ecological risk assessment (see ATTACHMENT B.1). Sample locations are presented in Figure B.17 and a summary of the data is presented in Table B.19.

B.6 Small Mammals

The data gaps exercise identified that there was a lack of small mammal data at the Giant Mine. Therefore Golder (2016e) undertook a program to characterize terrestrial small mammals on the Giant Mine and former Townsite (see ATTACHMENT B.1). A total of 50 northern red backed vole, deer mice or shrew samples were obtained for analysis. Sample locations are presented in Figure B.18 and a summary of the data is presented in Table B.20 for the Giant Mine and Table B.21 for the former Townsite.

Figure B.18 Small mammal sampling locations from Giant Mine and former Townsite

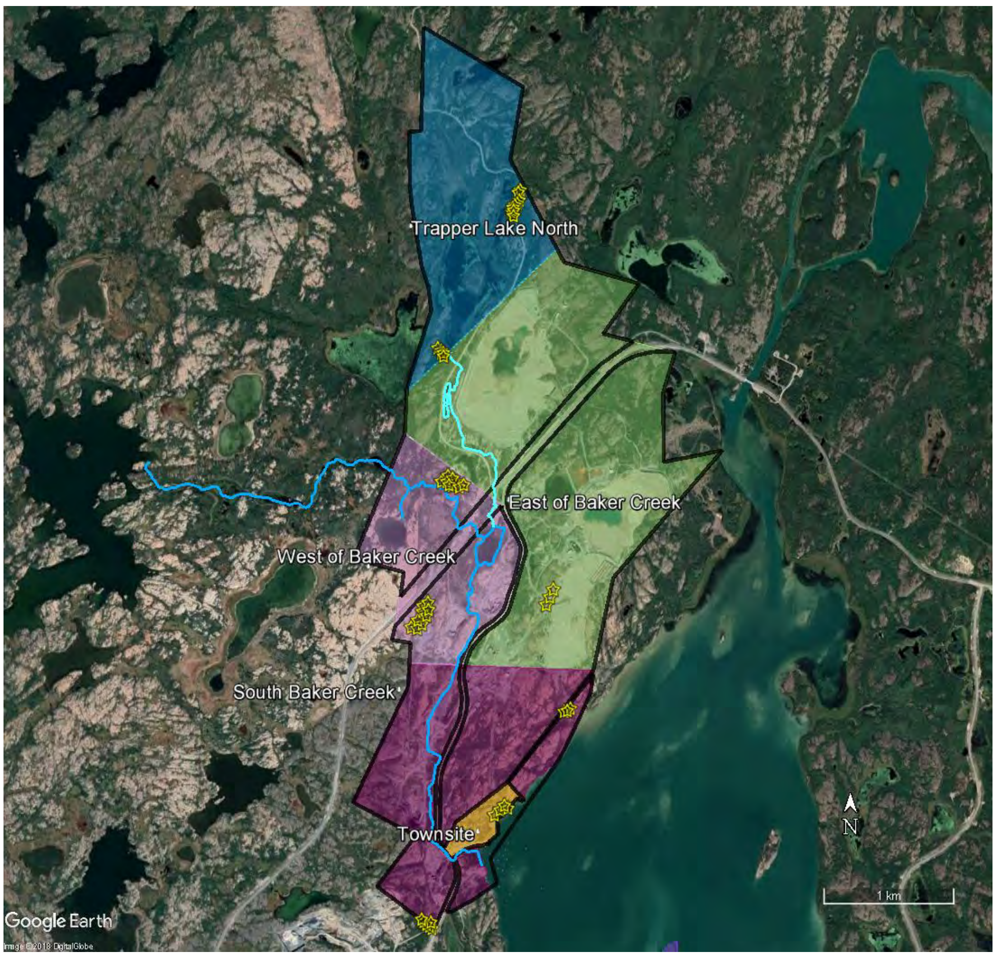

Table B.20 Summary of concentrations in small mammals on Giant Mine

B.7 Fish

There have been several fish studies carried out in Baker Creek and Yellowknife Bay since 2011 that are considered appropriate for consideration within the risk assessment. In examining the fish data there are different requirements from both a human health and ecological perspective. For human health, fish tissue that is consumed by people is the focus of the summaries. Discussions with the YKDFN community indicated that they consume trout, lake whitefish, and inconnu. For the ecological risk assessment, whole body fish are the focus.

B.7.1 Whole Body Fish from Baker Creek

Two sampling programs were identified to characterize whole body fish in Baker Creek (Golder 2013a; Stantec 2014a). All samples were obtained from lower Baker Creek (Reach 0 and Reach 1) with 36 samples of slimy sculpin, nine spine stickleback, and arctic grayling obtained for analysis for most constituents. A summary of the data is presented in Table B.22.

Table B.22 Summary of whole body concentrations fish from Baker Creek

B.7.2 Whole Body Fish from Yellowknife Bay

Only one sampling program was identified to characterize whole body fish in Yellowknife Bay (Stantec 2014a). A total of 61 samples of slimy sculpin were obtained from North Yellowknife Bay and South Yellowknife bay near the City of Yellowknife. A summary of the data is presented in Table B.23.

B.8 Background

A summary of available data from background locations is provided in Appendix C.

B.9 Voluntary Sampling Program

A summary of the results of voluntary sampling program which took place from September 2016 to January 2017 is provided below.

B.9.1 Overview and Methods

The purpose of the voluntary sampling program was to collect samples of country foods that are consumed from people who live in the area around the Giant Mine site (City of Yellowknife, Ndilo, or Dettah) to inform the Human Health Risk Assessment (HHRA). Samples were submitted from various people from the YKDFN, NSMA as well as people living in Yellowknife for a wide range of country foods including small and large mammals, birds, fish, plants, and mushroom.

A list containing details of each of the samples submitted to the laboratory for chemical analysis as part of this program are provided below in Table B.26. In some cases the organ samples listed in Table B.26 represent a composite of organs from more than one animal.

An overview of the samples submitted for analysis is shown in Table B.27. While 103 sample numbers were assigned (as seen in Table B.26), some of the samples did not end up being collected and thus some of the numbers were skipped. Overall, 94 samples were submitted to the laboratory including 14 large game, 8 small game, 30 birds, 9 fish, 32 plants, and 1 mushroom sample. It should be noted that this represents a very good sampling effort for the purposes of the risk assessment.

Table B.26 Summary of Submitted Samples

#	Sample Code	Date (dd/mm/yr)	Species	Additional Detail	Location	Comments
1	2385_GIANT_001	18/09/16	Cranberries	-	Yellowknife River	-

103	2385_GIANT_103	25/01/17	Rabbit	Leg meat	Dettah road	Fresh; was frozen at the lab.

Table B.27 Overview of samples submitted for analysis

Sample Type	Sample Species (Number of Samples Submitted)		Tissues Sampled
Plants	• Cranberries (11) • Labrador tea (4) • Raspberries (4) • Rose Hips (3) • Red Bear berries (1)	• Juniper berries (2) • Spruce gum (4) • Saskatoon berries (1) • Chives (1) • Birch Syrup (1)	Berries, gum, syrup, tea
Fungi	• Mushroom (1)		
Birds	• White Winged Scoter (3) • Canada Goose (1) • Ptarmigan (12)	• Black Ducks (5) • Mallard Ducks (2) • Spruce Grouse (6) • Lesser Scaup (1)	Flesh, Fat, Gizzard, Liver, Heart
Mammals	• Moose (10) • Muskox (1) • Muskrat (2) • Rabbit (2)	• Bear (1) • Beaver (4) • Caribou (1) • Reindeer (1) [a]	Flesh, Liver, Heart, Fat
Fish	• Lake Trout (5)	• White Fish (4)	Flesh, Eggs

Note: a – Reindeer sample from Inuvik, which is 200+ km away.

B.9.2 Sample Locations

Figure B.19 through to Figure B.23 show the approximate locations where the voluntary samples were obtained. As can be seen, around half (43) of the samples are from within 10 km of the Giant Mine; of these samples, quite a few of the berries and other plants are from Ndilo. Twenty-four (24) of the samples were collected from between 10 km and 25 km of the Giant Mine, 10 samples were obtained between 25 km and 50 km of the site, and 9 samples were obtained between 50 km and 100 km from the site. The remaining 8 samples were collected more than 100 km from the Giant Mine.

This sample distribution of more than half of the samples within a 10 km of the site and the rest further away is considered to be a good representation of the potential influence of the Giant Mine on the level of contaminants in country food.

Figure B.19 Voluntary samples from within 10 km of the Giant Mine Site

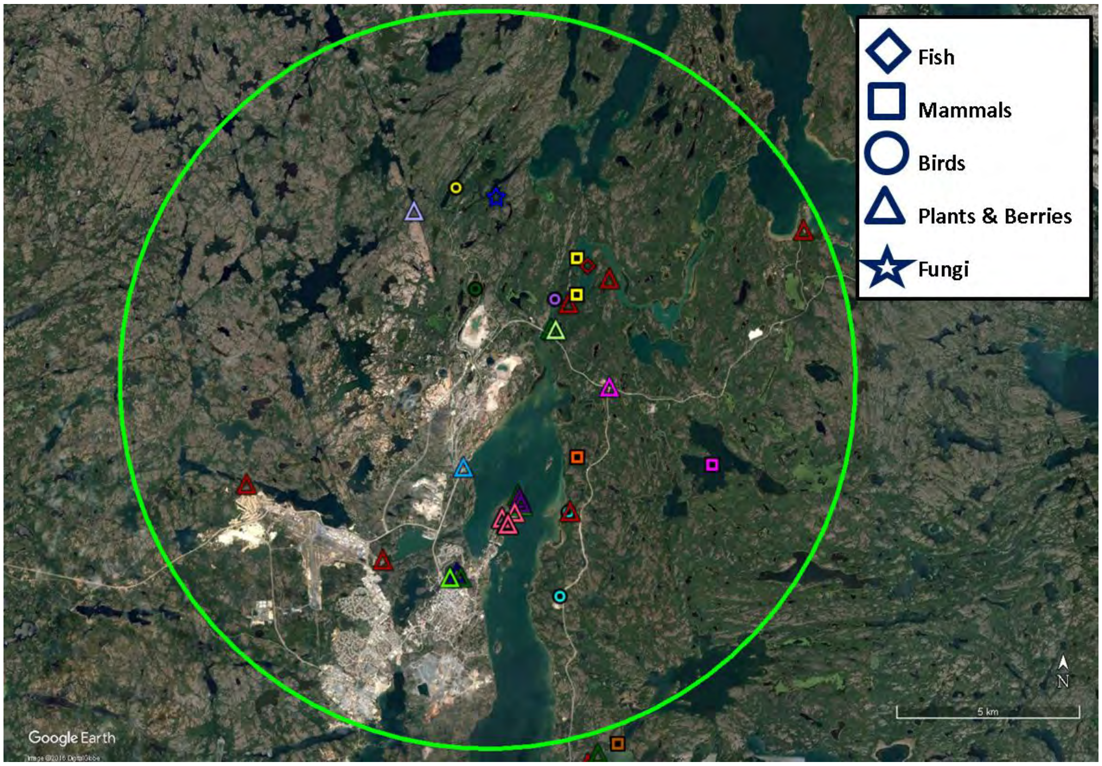

Figure B.20 Voluntary samples from the Ndilo Area

Figure B.21 Voluntary samples from within 25 km of the Giant Mine Site

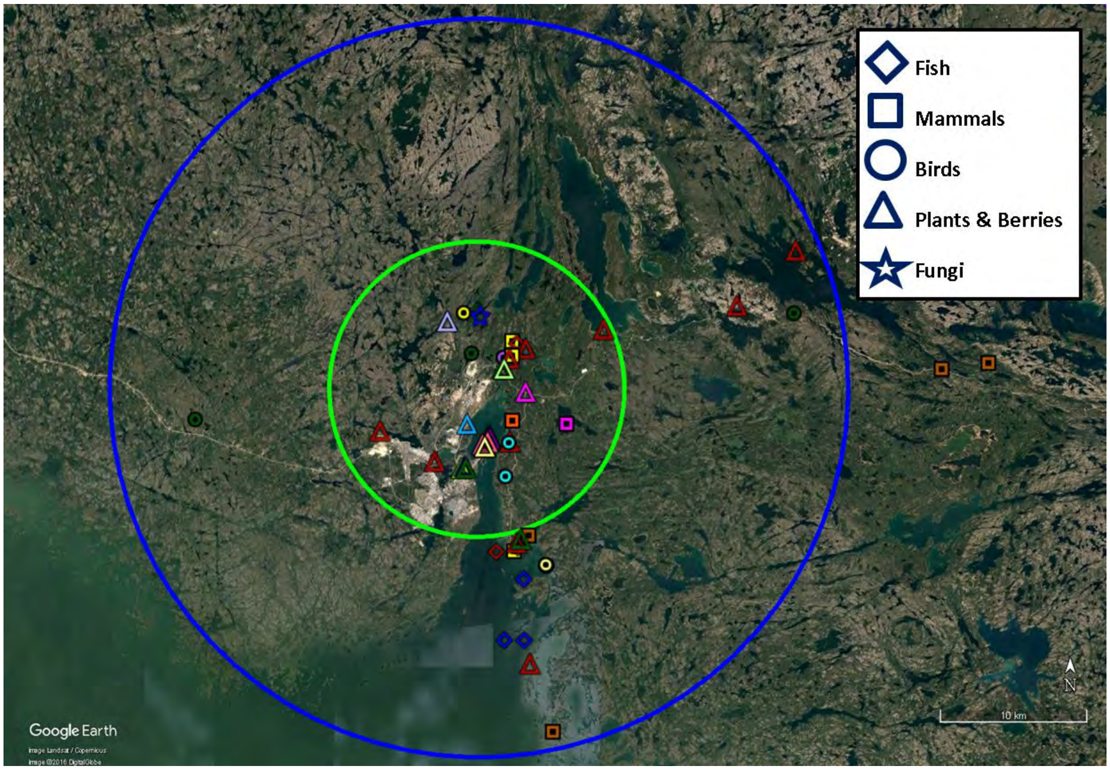

Figure B.22 Voluntary samples from within 50 km of the Giant Mine Site

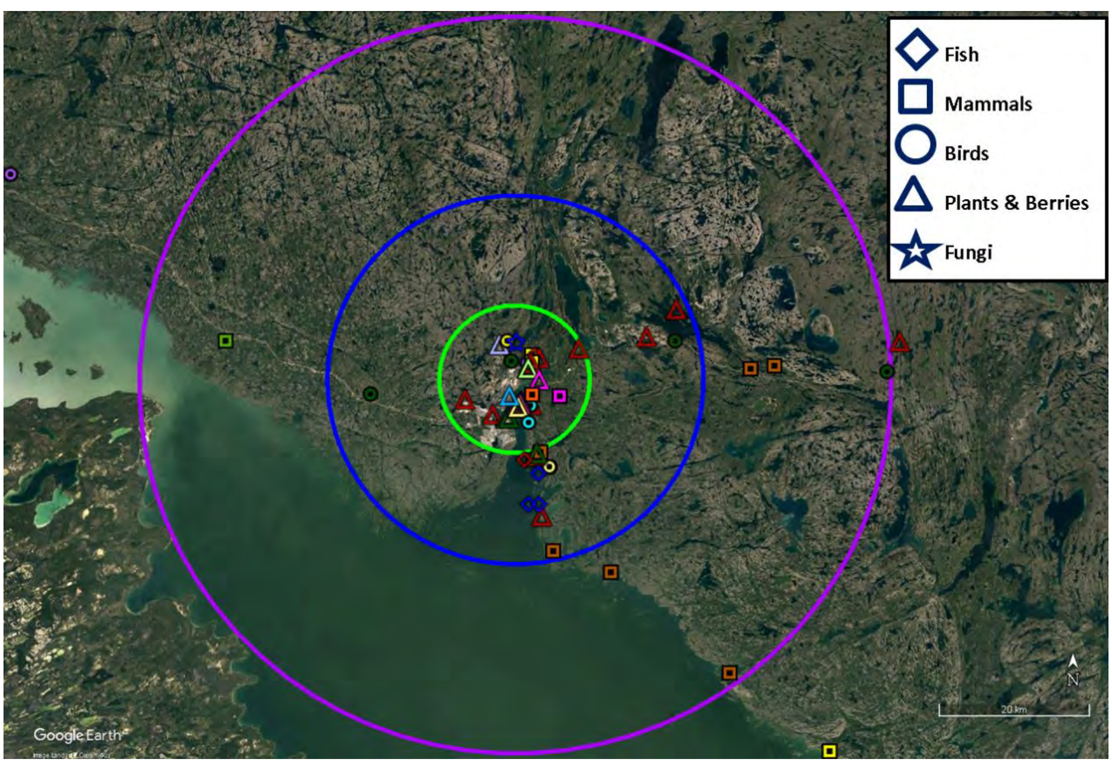

Figure B.23 Voluntary samples from within 100 km of the Giant Mine Site

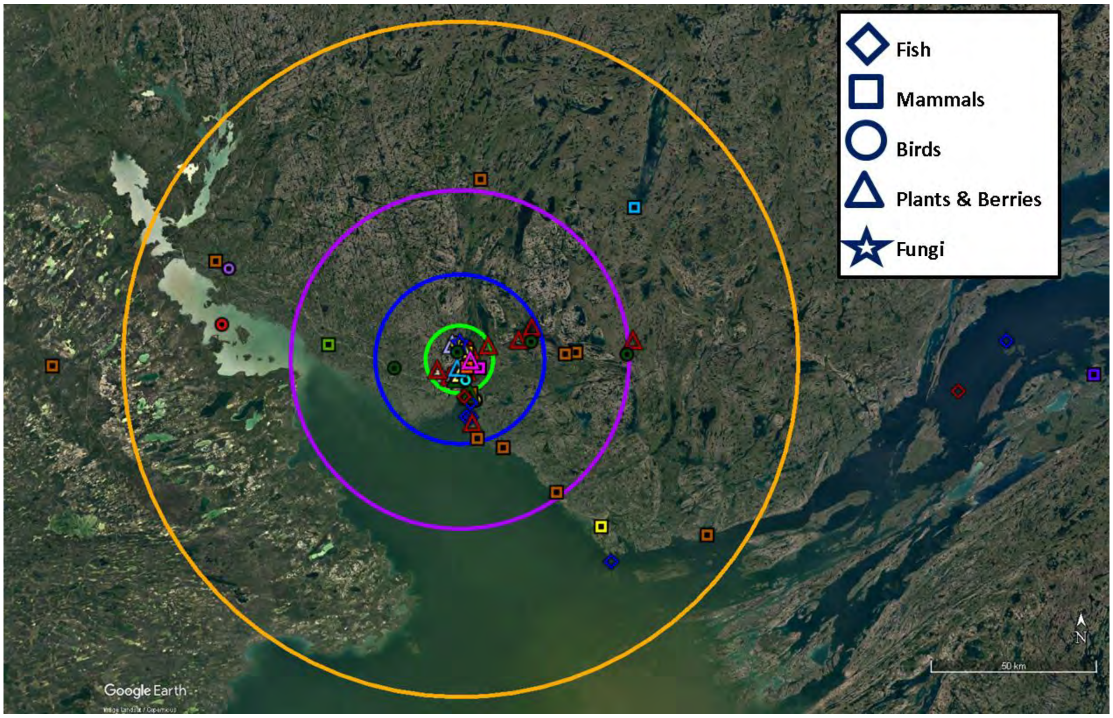

Table B.28 Measured concentrations in country foods

GOLDER (2016) HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT DATA GAPS

TECHNICAL MEMORANDUM

DATE	December 21, 2016	**REFERENCE No.**	414-HHRA-25-TECH MEMO-0001-Rev0_20161221 (HHERA data gaps)
TO	Mr. Greg Wright AECOM Canada Ltd		
CC	David Hango, Public Works and Government Services Canada; Steven Fiddler, Golder Associates Ltd.		
FROM	Tamika Mulders, Lilly Cesh, Audrey Wagenaar, and Damian Panayi	**EMAIL**	Tamika_Mulders@golder.com, Lilly_Cesh@golder.com, Audrey_Wagenaar@golder.com, Damian_Panayi@golder.com

GIANT MINE DATA REPORT - HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT DATA GAPS

1.0 INTRODUCTION

Golder Associates Ltd. (Golder) was retained by AECOM Canada Ltd. (AECOM) and Public Works and Government Services Canada (PWGSC) to collect samples (e.g., soil, sediment, water, vegetation, and small mammals) to fill data gaps for the Human Health and Ecological Risk Assessment (HHERA) currently being completed at Giant Mine (hereafter referred to as the Site). The samples collected were based on the data gaps identified by Canada North Environmental Services (CanNorth). The samples collected focused on the Giant Mine Townsite and Shoreline Lands, the Baker Creek watershed, the undisturbed areas of the Giant Mine lease, Long Lake, and the Yellowknife River watershed. This memorandum presents the field methods for the sample collection, the locations of the samples, and the results of the chemical analysis.

2.0 SAMPLE COLLECTION METHODS AND CHEMISTRY RESULTS

2.1 Giant Mine Townsite and Shoreline Lands

Sediment Samples

Samples were collected from ten (10) stations between August 23 and August 25, 2016. Sample stations were located between the Foreshore Tailings and the mouth of Baker Creek (Figure 1). Analysis of the samples for arsenic bioaccessibility are provided in this memorandum. The results of analysis for total metals will be provided in a separate memo expected to be available in January 2017.

At each station, water depth and physico-chemical measurements were collected prior to collecting the sediment sample (Table 1). Total depth of the water column was measured using a depth sounder (Hummingbird Helix 5 SI GPS). *In situ* physico-chemical measurements of specific conductivity, dissolved oxygen, pH, and water temperature were collected at each station using a submersible multi-sensor probe (YSI model 600QS-O-M). Three duplicate sediment samples were collected.

Following the collection of the *in situ* field measurements, a Tech-Ops sediment sampler was used to collect sediment core samples (Appendix A, Photograph 1). Three core samples were collected at each station , each core divided into 5 centimetre (cm) intervals representing 0 to 5 cm, 5 to 10 cm, and greater than 10 cm depth ranges. Each depth interval was mixed thoroughly in a stainless steel bowl until it was homogeneous in colour and texture creating one composite core sample of sediment for each depth interval (Appendix A, Photograph 2). The composite samples were then transferred into laboratory-supplied containers, kept cool and shipped to the Royal

Military College of Canada (RMC) in Kingston, Ontario for arsenic bioaccessibility analysis under the supervision of Dr. Iris Koch.

A summary of the samples collected and field measurements are provided in Table 1. The arsenic bioaccessibility results are provided in Table 2 and the laboratory report is provided in Appendix B.

Soil Samples

Soil samples were collected between August 12 and 17, 2016 at ten (10) stations including four (4) outcrop stations, four (4) forest stations, and two (2) wetland stations (Figure 1; Appendix A, Photographs 3 and 4).

Soil samples were collected using hand tools including a soil trowel, a shovel, and/or a hand auger. Outcrop stations were selected at outcrop crevasses and two soil samples were collected per station. Outcrop soil samples were collected at depth intervals 0 to 5 cm and 20 to 30 cm. Forest stations were identified in areas with stable vegetative cover typically located along the edges of bedrock outcrops. Wetland stations were selected in low lying areas typically between outcrops where standing water had potential to be present. Three soil grabs were collected from each forest and wetland station at depth intervals of 5 to 10 cm, 20 to 30 cm, and 60 to 80 cm. Soil samples were placed in re-sealable plastic bags and submitted to RMC in Kingston, Ontario for arsenic bioaccessibility analysis under the supervision of Dr. Iris Koch.

A summary of the samples collected and field measurements are provided in Table 3. The arsenic bioaccessibility results are provided in Table 4 and the laboratory report is provided in Appendix B.

2.2 Co-Located Sediment and Aquatic Plant Samples

Sediment and aquatic plant sampling was conducted on September 23, 2016. Ten (10) co-located (i.e., collected within 10 m^2) sediment and aquatic plant samples were collected in each of three areas: lower Baker creek, upper Baker creek, and the Yellowknife River (Figures 2 and 3). Photographs were taken at each location of substrate collected and the surrounding area (Appendix A, Photograph 5). Sediment samples were collected using a stainless steel hand shovel. Samples were placed in a stainless steel bowl and mixed to homogenize the sample. Following the homogenizing, the sample was placed in clean 125 mL glass jars provided by ALS Environmental Laboratory (ALS) in Yellowknife, NT. Sampling equipment was cleaned with Liquinox soap and rinsed with deionized water between each site. Nitrile gloves were used for all contact with samples and were changed at each site. Sediment samples were kept on ice in a cooler and then transferred to a refrigerator at the end of the day. Samples were keep cool in the refrigerator until submitted to ALS in Yellowknife, NT for the analysis of total metals.

Aquatic plants such as water sedge (*Carex aquatilis*) and cattail (*Typha latifolia*) were collected to represent aquatic plant species. The aquatic plants samples include a number of different plant species and varies depending on what was available at each location. One species was collected at each site. Only healthy plant samples were collected (i.e., no visible signs of disease or yellowing). Aquatic plants were collected by hand. Samples were double-bagged in re-sealable plastic bags, labelled, and kept cool until they could be frozen at the end of the day. Nitrile gloves were used for all contact with samples and were changed at each site. Aquatic plants samples were submitted to ALS in Yellowknife, NT for total metals analysis. Aquatic plant samples for arsenic bioaccessibility were collected at five stations, from the three areas (lower Baker creek, upper Baker creek, and the Yellowknife River), and sent to RMC in Kingston, Ontario for analysis under the supervision of Dr. Iris Koch.

Duplicate samples were taken at three locations, one in each area (lower Baker creek, upper Baker creek, and the Yellowknife River). Sediment duplicate samples were sampled by collecting twice as much sediment from a location, homogenizing the sample in a bowl, and then filling twice as many jars. Aquatic plant duplicate samples were collected at the same locations as the sediment duplicates. Aquatic plant sample duplicate samples were sampled by collecting twice as much, mixing the plants in a large bag, and dividing the sample into two re-sealable plastic bags to be analyzed separately.

A summary of the samples collected and field measurements are provided in Table 5. The chemistry results are provided in Tables 6 (sediment) and 7 (aquatic plants) and the bioaccessibility results for the aquatic plants are provided in Table 8. The laboratory reports are provided in Appendix B. The relative percent differences (RPD) calculations for duplicate samples are provided in Appendix C.

2.3 Co-Located Soil and Vegetation Samples

Co-located soil and vegetation samples were collected from September 7 to September 11, 2016. Each soil sample was co-located (within 10 m^2) of each plant tissue sample. Soil was collected using a stainless steel hand shovel. After removal of top layer of organic material, the field crew collected surficial soil up to top 15 cm if available. The soil depth was measured with a ruler and recorded. Soil was mixed in the stainless steel bowl to homogenize the sample, rocks and debris were removed before being placed in the sample container (Appendix A, Photograph 6). Headspace was minimized in sample containers. Nitrile gloves were used for all contact with soil and changed between samples. Sampling equipment was washed with Liquinox soap and rinsed with deionized water after each sample. The soil collection locations are shown on Figure 2.

Leaves of cranberry (*Vaccinium vitis-idaea*) and alder (*Alnus* sp.) were collected to represent terrestrial forbs and shrubs (Appendix A, Photograph 7). Only healthy plant samples were collected (i.e. no signs of disease, yellowing leaves, breakage or missing leaves). Cranberry and alder leaves were collected by hand. Samples were double-bagged in re-sealable plastic bags, labelled, and kept cool until they could be frozen at the end of the day. Nitrile gloves were used for all contact with samples and were changed at each site and between samples. Plant samples (minimum of 5 g) were submitted to ALS in Yellowknife, NT for total metals analysis. Plant samples for arsenic bioaccessibility samples were collected at five stations of both cranberry and alder leaves and submitted to RMC in Kingston, Ontario for analysis under the supervision of Dr. Iris Koch. Cranberry and alder collection locations are shown on Figure 4.

Duplicate samples were collected at four locations. Soil duplicate samples were sampled by collecting twice as much soil from a location, homogenizing the sample in a bowl, and then filling twice as many jars. Plant duplicate samples were collected at the same locations as the soil duplicates. Plant duplicate samples were sampled by collecting twice as much, mixing the plants in a large bag, and dividing the sample into two re-sealable plastic bags to be analyzed separately.

A summary of the samples collected and field measurements are provided in Table 5. The arsenic bioaccessibility results for plants are provided in Table 8 and the chemistry results are provided in Tables 9 (soil), 10 (alder) and 11 (cranberry). The laboratory reports are provided in Appendix B. The relative percent differences (RPD) calculations for duplicate samples are provided in Appendix C.

2.4 Small Mammal Tissue Samples

Small mammal trapping was conducted according to the wildlife research permit (permit number WL 500470). Small mammal traps were set on September 6, 2016 and were checked each consecutive day until September 10, inclusive. Ninety-eight (98) commercial mouse traps were set on eight transects, each transect consisted of twelve (12) stations and stations were made up of clusters of two or three traps (Appendix A, Photograph 8). Stations were placed approximately 20 m apart, recorded with GPS waypoints and track files. Each transect consisted twenty-five (25) traps and the traps were moved to different transects as mice were caught. Traps were baited with a mixture of peanut butter and oats. A sample of the bait used to trap the small mammals was submitted to ALS in Yellowknife, NT for total metals analysis along with the carcasses. At stations where small mammals were caught, the field crew collected co-located (i.e., collected within 10 m^2) soil and vegetation samples (Figure 5). Samples were identified and weighed at the Yellowknife Golder lab at the end of each day, and were frozen in labelled re-sealable plastic bags until submitted to ALS in Yellowknife, NT for total metals analysis. Three small mammal species were caught, including deer mouse (*Peromyscus maniculatus*), northern red-backed vole (*Myodes rutilus*), and an unidentified shrew species (*Sorex* sp.).

A summary of the samples collected and field measurements are provided in Table 5. The chemistry results are provided in Table 12 and the laboratory reports are provided in Appendix B.

2.5 Long Lake Sample Collection Methods

Long Lake sediment, surface water, and soil sampling was conducted on September 21, 2016. Surface water and sediment were collected at ten (10) locations along the public beach, day use, and boat launch areas at Fred Henne Territorial Park. Soil samples were collected at ten (10) campsites in the Fred Henne Campground, focusing on areas that would be likely to be used for camping (e.g., setting up tents) (Figure 6). Samples were collected across the intended area for maximum coverage. One duplicate was taken of each sample type. Photos of the site and substrate and GPS waypoints were recorded at each location. All samples (33 in total, 11 of each medium) were submitted to ALS in Yellowknife, NT for the analysis for total metals. In addition, five (5) soil samples and five (5) sediment samples were also submitted to RMC in Kingston, Ontario for arsenic bioaccessibility analysis under the supervision of Dr. Iris Koch

Prior to the collection of surface water samples, an YSI multimeter and handheld pH meter were used to collect field parameters (Table 13; Appendix A, Photograph 9). Sample bottles were partially submerged in the lake, using nitrile gloves and taking care to avoid large debris or suspended solids. Surface water samples were collected prior to collecting sediment samples at the same location, to avoid stirring up substrate. Samples were labelled and kept cool until delivery to ALS in Yellowknife, NT. Due to a laboratory oversight, insufficient preservative vials had been included with the sample bottle set; however, samples were delivered to ALS the same day, within hold time requirements for total metals, and were preserved at the lab.

Sediment was collected at the same locations as surface water, from the upper 0.10 m of substrate. Stainless steel hand tools and a stainless steel bowl were used to sample and homogenize the substrate; rocks and organic debris were removed before placing the sample into a labelled re-sealable plastic bags. The substrate type and a description of the substrate type were recorded. Nitrile gloves were used for all contact with soil and changed between each sample. Sampling equipment was washed with Liquinox soap and rinsed with deionized water after each sample.

Soil was collected at locations dispersed throughout the campground area (Figure 6). Soil was collected at areas either on a camping pad clearing, or in cases of thick gravel covering limiting access to soil beneath, directly next to the gravel pad. Soil was collected using a stainless steel trowel and bowl. After removal of top layer of organic material, field crew collected surficial soil (top 15 cm) if possible, soil depth was measured with a ruler and recorded. Soil was mixed in the stainless steel bowl to homogenize the sample; rocks and debris were removed before being placed in the sample container. Nitrile gloves were used for all contact with soil and changed between samples. Sampling equipment was washed with Liquinox soap and rinsed with deionized water after each sample.

A summary of the samples collected and field measurements are provided in Table 13. The chemistry results for Long Lake are provided in Tables 14 (surface water), 15 (sediment) and 16 (soil). The arsenic bioaccessibility results for the Long Lake sediment and soil samples are provided in Table 17 and 18 respectively. The laboratory reports are provided in Appendix B and the relative percent differences (RPD) calculations for duplicate samples is provided in Appendix C.

3.0 CLOSURE

We trust that the information provided in this technical memorandum is sufficient for your present needs. Should you have any questions, please contact the undersigned.

16-Giant-AP-3-BIO *	3.2	3.8	83	0.042	1.1	52

Notes:
dw - dry weight
* - Average of the duplicate pair (BA conc) reported
NC - not calculated because As not detected in sample
CR/CB: Cranberry leaves; AL: alder leavesl; AP: aquatic plants
BA conc = concentration of bioaccessible element in soil
%BA = % bioaccessibility = 100% x bioaccessible As/total As;
LOD = limit of detection; LOD % BA = (LOD for bioaccess As Conc)/Total As * 100%.

Notes:
< Indicates parameter was below laboratory equipment detection limit.
> Indicates parameter detected above equipment analytical range
- Chemical not analyzed or criteria not defined.
N Indicates non-field-duplicate samples.
FD Indicates sample was a field duplicate.

Notes:
< Indicates parameter was below laboratory equipment detection limit.
> Indicates parameter detected above equipment analytical range.
- Chemical not analyzed or criteria not defined.
N Indicates non-field-duplicate samples.
FD Indicates sample was a field duplicate.

ANALYTICAL SCIENCES DIVISION
ANALYSIS REPORT COVER NOTE

Report Number: RMC-CCS-ES-16-038
Report Date: 1 December 2016
Sample(s) reported: 45
Issue Status: Final
Analysis commenced on: 3 October 2016

The following data are reported in this report: total arsenic, bioaccessible extracted arsenic, and percent bioaccessibility for 15 soil, 15 sediment and 15 plant samples.

Methods

All samples were received in good condition with the exception of two sediment samples found with leaking bags at the time of arrival (2016 SQ-1S-100-1 and 16-LongLake-SE-10).

Sediment samples were dewatered by filtration through 1.5 µm glass fiber filters (Whatman 1827-090, binder free, grade 934-AH, 90mm diameter) using vacuum filtration. The filtrates were frozen in vials until the time of analysis. Soil and dewatered sediment samples were oven dried, lightly ground to eliminate clumps, and sieved to a particle size of 250 µm. Plant samples were freeze dried and homogenized with a coffee grinder.

To obtain the bioaccessible arsenic for the human receptor, the ESG Glycine method (based on U.S. EPA SW-846 Method 1340) was employed. Each dried and homogenized sample was subsampled with a spatula, and soil and sediment samples were extracted in 50 mL extraction vessels with a 0.4 M solution of glycine adjusted to pH 1.5 in a liquid-to-(dry) solid ratio of 100:1. Plant samples were extracted using a liquid-to-(wet) solid ratio of 10:1 to simulate exposure to food. The extraction was carried out with end-over-end mixing at body temperature (37°C) for 1 hour.

All extracts and filtrates were analysed for total arsenic by ICP-MS, and total arsenic in sediment (dewatered <250 µm fraction), soil (<250 µm fraction) and plant samples were obtained by aqua regia digestions and analysis using ICP-MS at the Analytical Services Unit (ASU) at Queen's University, a CALA accredited laboratory.

To calculate % bioaccessibility, the following equation was used:

$$\% \, Bioaccessibility = \frac{Bioaccessible\ concentration\ \left(\frac{mg}{kg}\right)}{Total\ concentration\ (\frac{mg}{kg})} \times 100\%$$

Equation 1

To calculate % filtrate of sediment, the sediment dry weight (dw) concentration was first converted to wet weight using percent moisture:

$$Concentration\ \left(\frac{mg}{kg}ww\right) = \frac{Concentration\ \left(\frac{mg}{kg}dw\right) \times (100 - percent\ moisture)}{100}$$

Equation 2

The % filtrate of sediment is the concentration of arsenic in the water phase of the wet sediment (i.e., the filtrate concentration) as a fraction of the wet weight concentration:

$$\% \, Filtrate\ of\ sediment = \frac{Filtrate\ concentration\ (\frac{mg}{L})}{Sediment\ concentration\ (\frac{mg}{kg}ww)} \times 100\%$$

Equation 3

The % mobile arsenic in the sediment is the sum of the % bioaccessible and % filtrate arsenic.

Quality Assurance and Quality Control

Quality Assurance and Quality Control (QA/QC) samples were included for every eight samples during the bioaccessibility extraction and included a blank, standard reference material NIST 2711, blank spike and a sample duplicate. Blank samples were all below the limit of detection (0.2 mg/kg). The bioaccessibility of all standard reference material NIST 2711 samples were within the control limits established within the ESG laboratory. All spike recoveries were acceptable (100 ± 20 %). Precision was acceptable for all results with relative percent difference ($RPD = 100\% \times |\, value\ 1 - value\ 2| / (average\ of\ value\ 1\ and\ 2)$) less than 30%.

The QC results were reviewed for report ASU 15993 (Arsenic in extracts, arsenic in filtrates, arsenic in soil and arsenic in plants). The results for duplicates, blanks, 1643e CRM, EU-H-4 CRM and MESS 3 CRM and controls were all acceptable.

Data Interpretation and Limitations

Percent bioaccessibility for soil and sediment samples ranged from 7.0 to 55 %. Percent bioaccessibility for plant samples ranged from 14 to 118 %. Two plant samples (16-Giant-AP-11-BIO and 16-Giant-AP-16-BIO) had a percent bioaccessibility greater than 100 % (102 and 118%). Sample heterogeneity may have resulted in slight differences in the subsamples taken by ESG and by the laboratory conducting the total arsenic analysis, which may cause bioaccessibility to appear to be greater than 100%. Additionally the total arsenic concentration in sample 16-Giant-AP-16-BIO (0.86 mg/kg) was close to the limit of detection (0.50 mg/kg).

Data should be considered accurate to no more than two significant figures. This report is issued under final status.

The Environmental Sciences Group does not accept responsibility for the validity of procedures used to obtain or preserve the samples provided to the laboratory and does not accept any liability for the consequences of any acts taken or omissions made on the basis of the analysis or advice or interpretation provided. The results given relate only to the items tested.

Extraction Method:	Glycine bioaccessibility extraction of soils, sediment and plants
Analytical Method:	Total As by ICP-MS
# Samples:	45 (15 sediment, 15 soil and 15 plant)

Concentrations in mg/kg, based on DRY WEIGHT (dw), unless otherwise noted.
BA conc = concentration of bioaccessible element in dewatered sediment; Sediment conc = concentration (DW) of element in dewatered and dried sediment;
%BA = % bioaccessibility = 100% x bioaccessible As/total As;
Filtrate conc = concentration of element in filtrate (water) removed from sediment;
Sediment conc ww = wet weight sediment concentration, dewatered sediment concentration corrected for percent moisture (see cover letter);
% Filtrate of sediment conc ww = 100% x filtrate conc/Sediment conc ww;
% Mobile of total = 100% x (BA conc corrected for percent moisture + filtrate conc)/sediment conc ww;
LOD = limit of detection; LOD % BA = (LOD for bioaccess As Conc)/Total As * 100%.

Spinach	<0.5

Prepared by: .... Authorization: ....

NOTES: Scandium, Indium and Bismith were used as internal standards. Gas dilution (HMI) used: Y

** Samples were pre screened using ICP-OES. Any values found to be <5 ppm by ICP-OES were reanalyzed by ICP-MS.

Reference Information

Qualifiers for Sample Submission Listed:

Qualifier	Description
WSMT	HG-T - Water sample(s) for total mercury analysis was not submitted in glass or PTFE container with HCl preservative. Results may be biased low.

Sample Parameter Qualifier Key:

Qualifier	Description
HTC	Hardness was calculated from Total Ca and/or Mg concentrations and may be biased high (dissolved Ca/Mg results unavailable).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ETL-HARDNESS-TOT-ED	Water	Hardness (from Total Ca and Mg)	APHA 2340 B-Calculation
HG-200.2-CVAA-ED	Soil	Mercury in Soil by CVAAS	EPA 200.2/1631E (Mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAAS.

ALS Test Code	Matrix	Test Description	Method Reference**
HG-T-CVAA-ED	Water	Total Mercury in Water by CVAAS	EPA 1631E (mod)

Water samples undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS.

ALS Test Code	Matrix	Test Description	Method Reference**
MET-200.2-CCMS-ED	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

ALS Test Code	Matrix	Test Description	Method Reference**
MET-T-CCMS-ED	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
ED	ALS ENVIRONMENTAL - EDMONTON, ALBERTA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

NOTES & CONDITIONS:

1. Quote number must be provided to ensure proper pricing.

2. Turnaround times will vary dependent on complexity of analysis & Lab workload at time of submission. Please contact the Lab to confirm turnaround time.

3. All hazardous samples submitted must be labeled to comply with WHMIS and TDG regulations. This must include the nature of the hazard, as well as a contact name & phone number that the Lab can contact for further information.

4. Failure to properly complete all portions of this form may delay analysis.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAA-ED	Soil	Mercury in Soil by CVAAS	EPA 200.2/1631E (Mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAAS.

ALS Test Code	Matrix	Test Description	Method Reference**
MET-200.2-CCMS-ED	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
ED	ALS ENVIRONMENTAL - EDMONTON, ALBERTA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

NOTES & CONDITIONS:

1. Quote number must be provided to ensure proper pricing.

2. Turnaround times will vary dependent on complexity of analysis & Lab workload at time of submission. Please contact the Lab to confirm turnaround time.

3. All hazardous samples submitted must be labeled to comply with WHMIS and TDG regulations. This must include the nature of the hazard, as well as a contact name & phone number that the Lab can contact for further information.

4. Failure to properly complete all portions of this form may delay analysis.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AG-DRY-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

AG-WET-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

HG-WET-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (WET)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

NOTES & CONDITIONS:

1. Quote number must be provided to ensure proper pricing.

2. Turnaround times will vary dependent on complexity of analysis & Lab workload at time of submission. Please contact the Lab to confirm turnaround time.

3. All hazardous samples submitted must be labeled to comply with WHMIS and TDG regulations. This must include the nature of the hazard, as well as a contact name & phone number that the Lab can contact for further information.

4. Failure to properly complete all portions of this form may delay analysis.

GUIDELINES/REGULATIONS	SPECIAL INSTRUCTIONS / NATURE OF HAZARDOUS MATERIAL	SAMPLE CONDITION		
	Stored on Ice. Please ship samples to ALS Burnaby for analysis, contact Steven Fiddler once samples have been recieved in Burnaby. Analysis should be done to the lowest detection limit possible. Plant samples are NOT to be washed prior to analysis. Analysis to be reported in both wet and dry weight.	X	FROZEN	MEAN TEMPERATURE

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AG-DRY-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

AG-WET-CCMS-N-VA	Tissue	Silver in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

HG-WET-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (WET)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.

mg/kg - milligrams per kilogram based on dry weight of sample

mg/kg wwt - milligrams per kilogram based on wet weight of sample

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight

mg/L - unit of concentration based on volume, parts per million.

< - Less than.

D.L. - The reporting limit.

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.
