LIST OF FIGURES

LIST OF TABLES

APPENDIX J: ECOLOGICAL RECEPTOR SELECTION AND DETAILED PROFILES

J.1 Ecological Receptor Selection

J.1.1 Background

A migratory bird survey was conducted between May and October 2004 on site by Cyngus Environmental (2005). A total of 89 species were detected. These surveys indicated that disturbed tailings areas and associated water bodies were not used extensively by waterfowl, likely due to the ample selection of undisturbed water bodies adjacent to the site (Golder 2016). Birds observed nesting on buildings at the site include barn swallow (*Hirundo rustica*), great horned owl (*Bubo virginianus*), cliff swallow (*Petrochelidon pyrrhonota*), American kestrel (*Falco sparverius*), osprey (*Pandion haliaetus*), northern flicker (*Colaptes auratus*), eastern phoebe (*Sayornis phoebe*), and common raven (*Corvus corax*) (Cygnus Environmental 2005; Golder 2012, 2013a, 2015, 2016).

Golder (2016) identified six avian species of concern with ranges that are known to overlap or potentially overlap with Yellowknife: short-eared owl (*Asio flammeus*), common nighthawk (*Chordeiles minor*), olive-sided flycatcher (*Contopus cooperi*), rusty blackbird (*Euphagus carolinus*), barn swallow (*Hirundo rustica*), horned grebe (*Podiceps auritus*). Short-eared owl, common nighthawk, olive-sided flycatcher and rusty blackbird have not been observed at the site during any of the surveys. Barn swallows are regularly present, and they are considered Threatened according to Committee on the Status of Endangered Wildlife in Canada (COSEWIC) but are not listed under the Species at Risk Act (SARA). The barn swallow has no status under the Northwest Territories (NWT) list of species at risk (ENR 2016). Horned grebes are present is small ponds and swamps of the Yellowknife area and were observed on the Mill Pond 11 in 2015. They are considered Special Concern under COSEWIC but are not listed under the SARA. The horned grebe has no status under the NWT list of species at risk (ENR 2016).

Based on the wildlife survey conducted at the site, coyote (*Canis latrans*), red fox (*Vulpes vulpes*), snowshoe hare (*Lepus americanus*), red squirrel (*Tamiasciurus hudsonicus*), ptarmigan (*Lagopus lagopus*), and small mammal species (mice, voles, shrews) are common on the Giant Mine.

The little brown bat (little brown myotis) (*Myotis lucifugus*) has been assessed as Endangered by COSEWIC but has not been assessed in the NWT (ENR 2016). In the

NWT, it has been found north and south of Great Slave Lake and in the Dehcho (ENR 2016); therefore, it may be potentially present at the Giant Mine. One other mammal of concern was identified as having a range that includes the Giant Mine is the wolverine (*Gulo gulo*). Wolverine has been identified as Special Concern under COSEWIC but is Not at Risk in the NWT (ENR 2016). Due to habitat requirements, the wolverine would not be expected to be present at the site.

J.1.2 Aquatic Receptors

The selection of the receptors to be included in the aquatic environment was based on an understanding of the Giant Mine as well as consideration of the previous assessments and discussions with stakeholders. Table J.1 provides the ecological receptors selected in the aquatic environment.

Table J.1 Ecological receptors selected for the aquatic environment

Aquatic Receptor Group	Aquatic Receptor Type	Selected Receptor
Water column organisms	Phytoplankton	Phytoplankton Community
	Zooplankton	Zooplankton Community
Benthic Invertebrates	Benthos Community	Benthic Invertebrate Infaunal Community
Fish	Benthivorous Planktivorous Piscivorous	Stickleback; Sculpin Arctic Grayling Northern Pike
Mammal	Herbivorous Insectivorous Piscivorous	Muskrat Bat (Little Brown Myotis) Mink
Bird	Herbivorous Insectivorous Piscivorous	Mallard Barn Swallow Horned Grebe, Osprey, Merganser

The aquatic biota were selected to be consistent with a previous assessment of Baker Creek (Golder 2013b). Amphibians and reptiles have not been observed at the site and were, therefore, not included in the assessment. This was discussed with Environment Canada and Climate Change (ECCC) and is consistent with the previous Golder (2013b) study.

Muskrat and mink were included as mammals with a diet primarily in the aquatic environment. The diet for these receptors includes a range of food species and, therefore, a separate omnivore was not identified.

The horned grebe was selected as it has been observed on the site and is a Special Concern under COSEWIC. It is a diving water bird that consumes aquatic insects and small fish.

The little brown bat and barn swallow both consume a diet of flying insects; benthic invertebrates comprise the larvae stage of many flying insects; thus, there is a connection between insectivores and the aquatic environment. The barn swallow was selected as it has been observed on the site and has been classified as Threatened under COSEWIC. It should be noted that since they build their nest almost exclusively on manmade buildings, they may not be present in the future with the same frequency as currently observed, but are included to represent insectivorous birds. Little brown bats may be present in the area and have been classified as Endangered under COSEWIC.

The osprey was included as a piscivorous bird. In addition, two ducks were included: a mallard (*Anas platyrhynchos*) that primarily consumes seeds and aquatic vegetation and a merganser (*Mergus merganser*) that consumes fish. The merganser was included, as the home range is much smaller than an osprey.

J.1.3 Terrestrial Receptors

The selection of the receptors to be included in the terrestrial environment was based on an understanding of the Giant Mine and with consideration of the previous assessments and discussions with stakeholders. The results of the previous ecological risk assessment (ERA) determined that large mammals were not at risk from exposure at the Giant Mine due to their wide home range. Therefore, the focus of this ERA is on mammals and birds with small home ranges. Table J.2 provides the ecological receptors selected for the terrestrial environment.

Table J.2 Ecological receptors selected for the terrestrial environment

Terrestrial Receptor Group	Terrestrial Receptor Type	Selected Receptor
Vegetation	Vegetation Community	Vegetation Community
Mammal	Herbivorous Insectivorous Carnivorous Omnivorous	Deer Mouse, Snowshoe Hare Bat (Little Brown Myotis), Masked Shrew Lynx Fox
Bird	Herbivorous Insectivorous Carnivorous	Willow Ptarmigan Barn Swallow Peregrine Falcon, Great Horned Owl

The deer mouse, masked shrew, snowshoe hare, great horned owl, fox, ptarmigan, and lynx have been observed on the Giant Mine. Consideration was given to include an omnivorous bird, but it was determined that this would not add any additional information, considering the range of receptors identified (i.e., robin has a similar home range as the herbivorous and insectivorous bird identified, and the diet is bounded by these receptors).

Consideration was also given to identifying invertebrates (i.e., ground-dwelling and aerial insects) as receptors for the terrestrial environment. Due to the bedrock outcroppings and climatic conditions, ground-dwelling invertebrates such as earthworms are not present in this location.

A bat species was chosen because the range includes the Giant Mine and the little brown myotis (*Myotis lucifugus*) has been identified as Endangered under COSEWIC. White nose fungus, which is the cause of the decline in bat populations across Canada, has not yet been found in the NWT (ENR 2016).

The barn swallow was selected as it has been observed on the site and has also been classified as Threatened under COSEWIC. It should be noted that, since they build their nests almost exclusively on man-made buildings, they may not be present in the future with the same frequency as currently observed as there will be minimal buildings on site; nonetheless, the barn swallow is included to represent insectivorous birds.

The peregrine falcon was included as a receptor. It has not been observed at the site but has the potential to be present. It was included in the Developer's Assessment Report (DAR; INAC/GNWT 2010) at the request of the Review Board. They are considered Special Concern under COSEWIC but are not listed under the SARA and have no status under the NWT list of species at risk (ENR 2016).

J.2 Receptor Exposure Pathways and Characteristics

The receptors selected cover a range of diets and trophic levels. Table J.3 summarizes the pathways of exposure that are considered for each of the receptors.

It should be noted that dermal exposure and inhalation are two pathways that are considered complete but will not be included in the ERA. Dermal exposure (direct contact with soil and sediment and transfer through the skin) for mammals and birds is usually considered to be insignificant, as the feathers of birds and fur on mammals reduce dermal exposure by limiting the contact of the skin surface with the contaminated media (U.S. EPA 2003). With respect to inhalation, none of the contaminants are volatile; however, there could be wind-blown dust. This exposure is expected to be much lower than those from other pathways such as food ingestion and is typically not included in ERAs (FCSAP 2012).

Table J.3 Exposure pathways for the selected receptors

Group	Receptor	Direct Contact (water)	Direct Contact (sediment or soil)	Water Ingestion	Sediment Ingestion	Soil Ingestion	Ingestion of Food	Food items
Water column organisms	Phytoplankton community	✓						
	Zooplankton community	✓						
Benthic invertebrates	Benthic invertebrate community	○	✓

	Peregrine Falcon			✓		✓	✓	Small mammals / birds

Notes: Direct contact with water includes absorption and uptake across surface membranes/gills, ingestion, as well as indirect pathways such as food.
Direct contact with sediment includes absorption and uptake across surface membranes, ingestion, as well as indirect pathways such as food.
* Included in both the aquatic and terrestrial environments; ○ Pathway of exposure implicitly included in the assessment.
✓ Pathway of exposure explicitly included in the assessment.

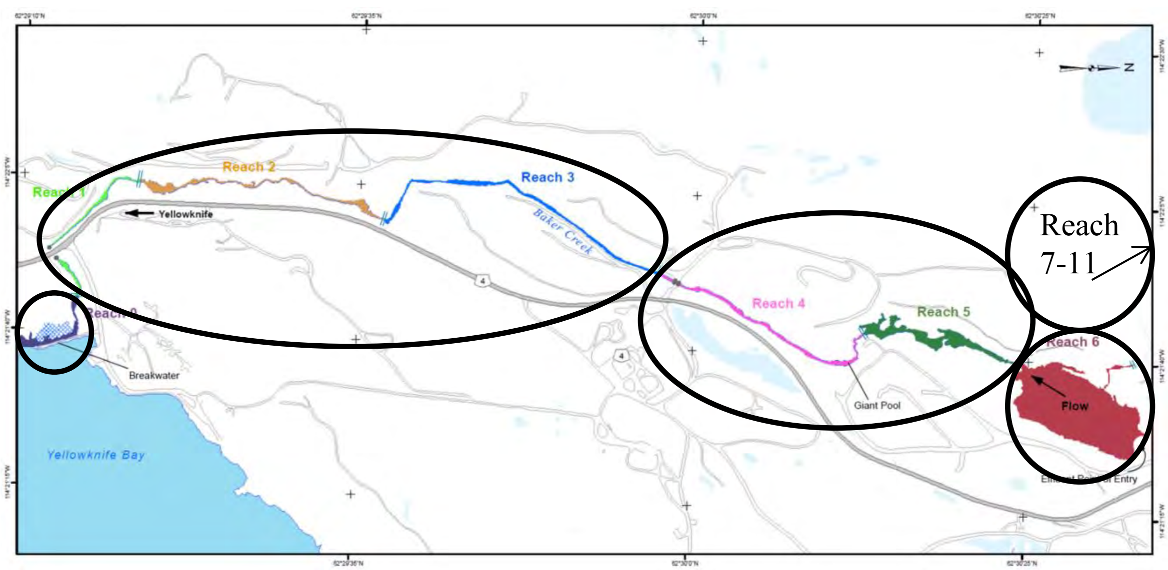
Section J.4 provides a summary of the receptor characteristics, including, for example, body weight, amount of food consumed, and diet composition. These were taken from FCSAP guidance where available, augmented by other literature as required.

J.3 Receptor Exposure Locations

The available data was divided into different segments of the site. For Baker Creek, five different segments were defined as shown in Figure J.1:

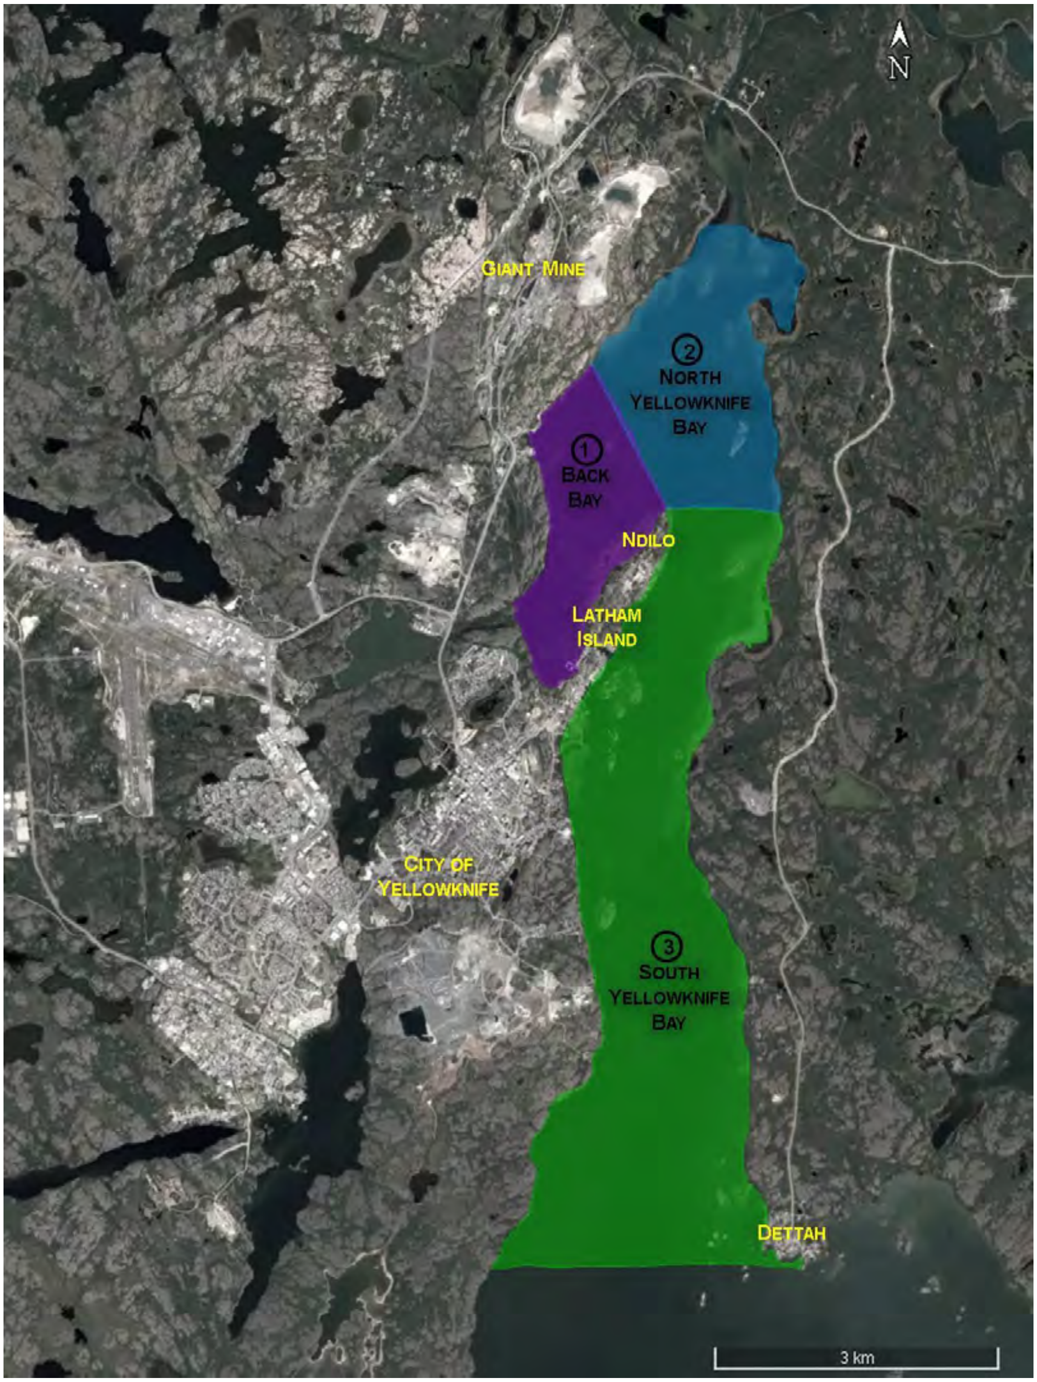
- Reach 0
- Reach 1-3
- Reach 4-5
- Reach 6
- Reach 7-11

Figure J.1 Segments of Baker Creek



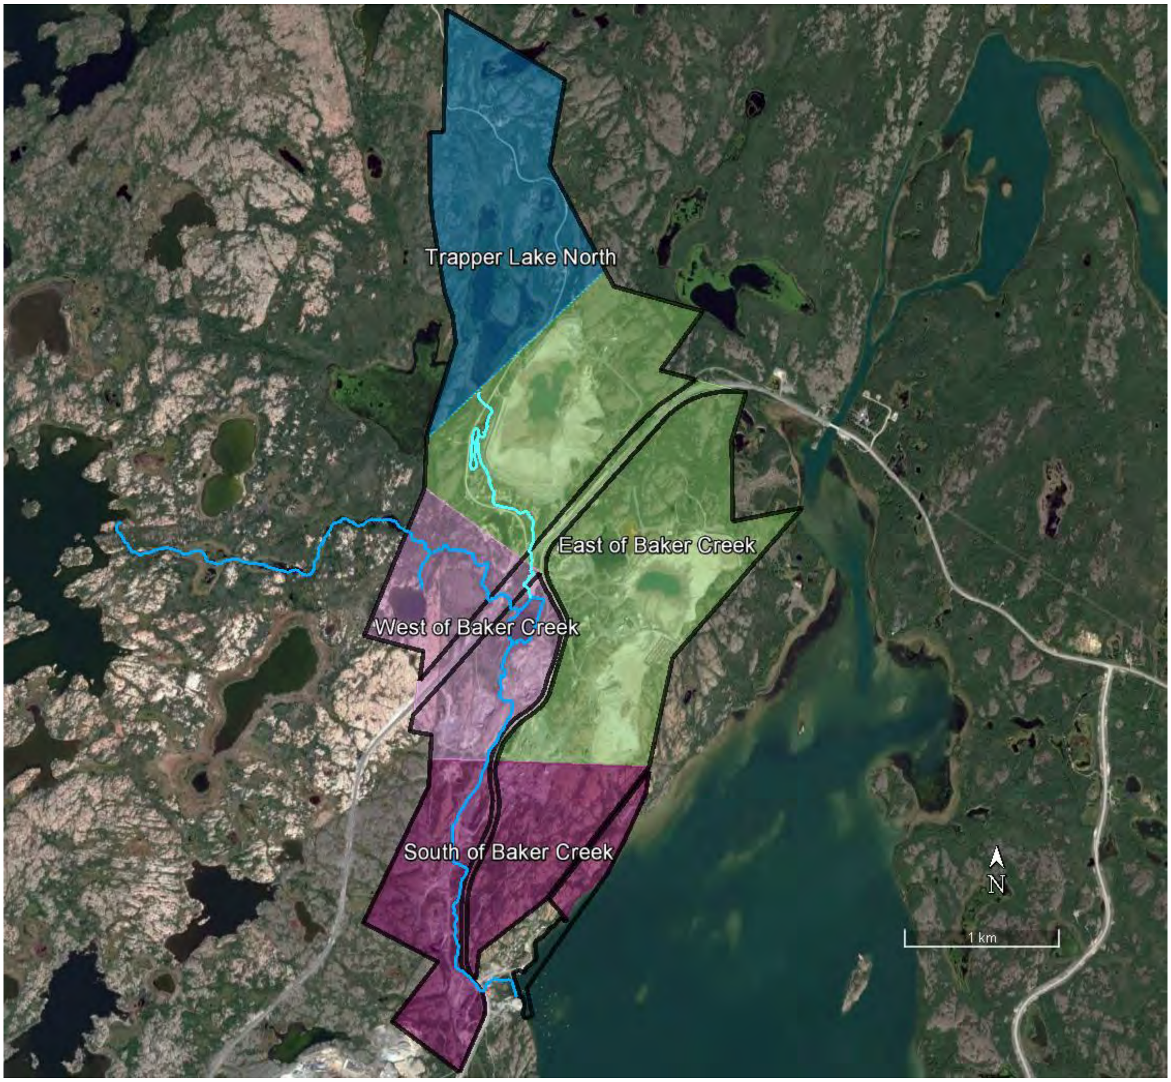
Yellowknife Bay was divided into three large segments as shown in Figure J.2. The assessment will focus on Back Bay section of Yellowknife Bay. This location is immediately downstream of Baker Creek and will receive the treatment plant effluent once the discharge location is moved.

Figure J.2 Segments of Yellowknife Bay



The on-site terrestrial environment of the Giant Mine Site was divided into four quadrants, as shown in Figure J.3.

Figure J.3 Terrestrial on-site quadrants considered for ERA



The selection of the location for the terrestrial receptors considers the habitat and use of the site as well as the foraging area of each receptor. Golder (2016) has indicated that Yellowknife is located in Nesting Zone C8, where nesting extends from May 8th through August 11th. For migratory species, although they are only present in the study area for part of the year, the fraction of time at site is assumed to be 1.0 for the purposes of the ERA, since the receptor is assumed to be present for a sufficient time on the Giant Mine such that effects could be realized.

A summary of selected locations for ecological receptors is provided in Table J.4 along with the amount of time spent at each location.

Table J.4 Locations assessed for ecological receptors

Receptor	Foraging Area (km^2) [(a)]	Locations [(b)]	Rationale
Aquatic Environment			
Phytoplankton community	NA	• Each segment of Baker Creek • Back Bay of Yellowknife Bay	Phytoplankton present in all locations.
Zooplankton community	NA	• Each segment of Baker Creek • Back Bay of Yellowknife Bay	Zooplankton present in all locations.
Benthic invertebrate community	NA	• Each segment of Baker Creek • Back Bay of Yellowknife Bay	Benthic invertebrates present in all locations.
Small-bodied resident fish (stickleback, sculpin)	NA	• Baker Creek • Back Bay of Yellowknife Bay	Fish can move throughout Baker Creek. Although Golder (2013b) indicate that small-bodied sentinel species have only been observed in Reach 0.
Large-bodied fish (arctic grayling, northern pike)	NA	• Baker Creek • Back Bay of Yellowknife Bay	Fish can move throughout Baker Creek.
Muskrat	< 0.001 to 0.008	• Each segment of Baker Creek • Back Bay of Yellowknife Bay	Small home range, assumed to be present at all locations.
Mink	0.06 to 16.3	• Baker Creek • Back Bay of Yellowknife Bay	Due to mid-sized home range evaluate on lower reaches of Baker Creek and on Back Bay.
Bat	0.3 - 1.4	• Baker Creek • Back Bay of Yellowknife Bay	Due to mid-sized home range evaluate on lower reaches of Baker Creek and on Back Bay.
Mallard	0.09 to 2.4	• Baker Creek • Back Bay of Yellowknife Bay	Due to mid-sized home range evaluate on lower reaches of Baker Creek and on Back Bay.
Horned Grebe	–	• Baker Creek • Back Bay of Yellowknife Bay	Due to mid-sized home range evaluate on lower reaches of Baker Creek and on Back Bay.
Barn Swallow	0.8 to 4.5	• Baker Creek • Back Bay of Yellowknife Bay	Due to mid-sized home range evaluate on lower reaches of Baker Creek and on Back Bay.
Osprey	1.7 to 10	• Baker Creek / Back Bay	Larger home range; will obtain food from a wider area.
Merganser	0.04 to 13.9	• Baker Creek • Back Bay of Yellowknife Bay	Due to mid-sized home range evaluate on lower reaches of Baker Creek and on Back Bay.
Terrestrial Environment			
Vegetation	NA	• Each quadrant of the site	Terrestrial vegetation present in all locations.
Deer Mouse	0.0001 to 0.004	• Each quadrant of the site	Small home range, assumed to be present at all locations.
Masked Shrew	0.006	• Each quadrant of the site	Small home range, assumed to be present at all locations.

Receptor	Foraging Area (km^2) [(a)]	Locations [(b)]	Rationale
Snowshoe Hare	0.016 to 0.1	• Each quadrant of the site	Small home range, assumed to be present at all locations.
Bat	0.3 - 1.4	• Each quadrant of the site	Mid-sized home range, assumed to be present at all locations.
Lynx	11 to 300	• Site-wide	Large home range. Assume half of exposure from site and half from other background sources.
Fox	2.8 to 34.2	• Site-wide	Due to mid-sized home range evaluate on a site-wide basis.
Willow Ptarmigan	0.067 to 0.079	• Each quadrant of the site	Small home range, assumed to be present at all locations.
Barn Swallow	0.8 to 4.5	• Each quadrant of the site	Mid-sized home range, assumed to be present at all locations.
Great Horned Owl	8 to 10	• Site-wide	Due to mid-sized home range evaluate on a site-wide basis.
Peregrine falcon	78 (16 to 1,508)	• Site-wide	Large home range. Assume half of exposure from site and half from other background sources.

Note: NA – Not Applicable.
a See Section J.4 for details.
b Details on how the exposure estimates were derived are provided in Appendix K.

J.4 Detailed Ecological Receptor Profiles

Table J.5 Little brown bat receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.01	According to Havens (2006), little brown bat range from 5 g to 14 g body weight (0.005 kg to 0.014 kg).
Water ingestion rate	m^3/d	1.5×10^{-6}	Based on U.S. EPA (1993) allometric equation for mammals.
Food ingestion rate – dry weight basis	g (dw)/d	1.5	Based on U.S. EPA (1993) allometric equation for all mammals.
Food ingestion rate – wet weight basis	g (ww)/d	3.8	Applies an assumed moisture content of 60% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	0.03	Based on generic soil ingestion rate for mammals (2% of a dry weight diet)
Foraging range	km^2	0.3 - 1.4	Little brown bats travel several kilometers between day roosts and feeding sites (Havens 2006). According to COSEWIC (2013), little brown bats forage within small (< 2 km^2) area. The home range of pregnant little brown bats in Quebec was 30 ha (0.3 km^2) (Henry et al. 2002). The mean home range area was 143 ha for bats in New York.
Diet Composition:			
Insects	–	1.0	Little brown bats feed largely on aquatic insects, including midges, caddisflies, moths, mayflies, lacewings, and occasionally mosquitoes (Havens 2006).

Table J.6 Peregrine falcon receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics			
Body weight	kg	0.815	Average value from EC (2012), based on Court et al. (1988), with range of 0.652 kg to 0.977 kg.
Water ingestion rate	m^3/d	5.1×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds (consistent with EC 2012 approach).
Food ingestion rate – dry weight basis	g (dw)/d	49	Based on EC (2012) (in U.S. EPA 1993) – 0.06 kg dry food/kg BW/day.
Food ingestion rate – wet weight basis	g (ww)/d	163	Calculated using an assumed moisture content of 70% for birds and mammals.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	0.98	EC (2012) did not identify an incidental soil ingestion rate specifically for falcon, but recommended a default value of 2%.
Foraging range	km^2	16 to 1,508	Range from EC (2012). Believed to largely forage within 5 km of breeding sites or within 78.5 km^2 area.
Diet Composition:			
Ptarmigan	–	0.90	According to EC (2012), the peregrine falcon is a hunting carnivore. Birds are the most common prey species (consumed 77 to 99% of the time). Consistent with EC (2012), 10% of the diet is attributed to small mammals.
Mice	–	0.10

Table J.7 Red fox receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics			
Body weight	kg	3.8	Average value from EC (2012), with range of 3.4 kg to 4.1 kg.
Water ingestion rate	m^3/d	3.3×10^{-4}	Based on U.S. EPA (1993) allometric equation for mammals (consistent with EC 2012 approach).
Food ingestion rate – dry weight basis	g (dw)/d	100	Calculated using the ww consumption rate in EC (2012) and an assumed moisture content of 70%.
Food ingestion rate – wet weight basis	g (ww)/d	340	Based on EC (2012) for adults in captivity (in U.S. EPA 1993) – 0.09 kg wet food/kg BW/day.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits
Soil ingestion rate	g (dw)/d	2.9	Based on EC (2012), using a 2.8% of dry weight food ingestion from Beyer et al. (1994).
Foraging range	km^2	2.8 to 34.2	Varies depending on season and location; range from EC (2012).
Diet Composition:			
Fruits and flowers	–	0.15	The fox is an omnivore, and primarily consumes small rodents, rabbits, and birds, with the addition of fruits and berries in the summer (EC 2012). Diet composition is consistent with EC (2012), with small mammals (40%) attributed equally to mice and hare, invertebrates (25%) attributed to insects, birds (20%) attributed to ptarmigan, and fruits and plant material (15%) attributed to fruits and flowers.
Insects	–	0.25	
Ptarmigan	–	0.2	
Hare	–	0.2	
Mice	–	0.2

Table J.8 Horned grebe receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.44	According to Cornell Lab of Ornithology (2015), horned grebe range from 300 g to 570 g (0.3 kg to 0.57 kg) body weight. COSEWIC (2009) is consistent with this information.
Water ingestion rate	m^3/d	3.4×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds (consistent with EC 2012 approach).
Food ingestion rate – dry weight basis	g (dw)/d	34	Based on U.S. EPA (1993) allometric equation for all birds (consistent with EC 2012 approach).
Food ingestion rate – wet weight basis	g (ww)/d	170	Applies an assumed moisture content of 80% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	1.6	Based on Beyer et al. (1994) for average duck species of 4.6% of dry weight food ingestion; distribution defined by range of body weights.
Soil ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Foraging range	km^2	No information available	
Diet Composition:			
Fish	–	0.1	The Horned Grebe is a diver that catches and eats most of its prey underwater (COSEWIC 2009). According to Cornell Lab of Ornithology (2015), aquatic insects, fish, crustaceans, and other small aquatic animals are the primary dietary components. According to Stedman (2000), they feed largely on aquatic arthropods during the breeding season, but their diet also includes fish, small frogs, salamanders and tadpoles. They will also pick insects from the water surface and aquatic plants.
Benthic invertebrates	–	0.9

Table J.9 Snowshoe hare receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	1.3	Average value from EC (2012), with range of 0.9 kg to 1.9 kg.
Water ingestion rate	m^3/d	1.3×10^{-4}	Based on U.S. EPA (1993) allometric equation for mammals (consistent with EC 2012 approach).
Food ingestion rate – dry weight basis	g (dw)/d	82	Based on EC (2012) for adults (both sexes) with a mixed diet of browse and commercial rabbit pellets – 0.06 kg dry food/kg BW/day.
Food ingestion rate – wet weight basis	g (ww)/d	270	Applies an assumed moisture content of 70% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	5.2	Consistent with EC (2012), based on U.S. EPA (1993) value for jackrabbit of 6.3% dry weight food ingestion.
Foraging range	km^2	0.016 to 0.1	Based on EC (2012).
Diet Composition:			
Foliage	–	0.3	Consistent with the dietary properties in EC (2012), with grasses (30%) attributed to foliage, shrubs (60%) attributed to woody vegetation, and berries (10%) attributed to fruits and flowers.
Woody vegetation	–	0.6	
Fruits and flowers	–	0.1

Table J.10 Canada lynx receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	11	According to CWF (2016), lynx range from 8 kg to 14 kg body weight.
Water ingestion rate	m^3/d	8.6×10^{-4}	Based on U.S. EPA (1993) allometric equation for mammals.
Food ingestion rate – dry weight basis	g (dw)/d	4.9×10^{2}	Based on U.S. EPA (1993) allometric equation for all mammals.
Food ingestion rate – wet weight basis	g (ww)/d	1.6×10^{3}	Applies an assumed moisture content of 70% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	13.8	Based Beyer et al. (1994) value for red fox of 2.8% of dry weight food ingestion.
Foraging range	km^2	11 to 300	Home ranges are larger in summer than winter (CWF 2016). Fox and Murphy (2002) provide a home range of 11 to 300 km^2.
Diet Composition:			
Hare	–	0.75	Snowshoe hare comprise more than 75% of the winter diet for the lynx, and continue to be the main part of the diet during summer months, with additional supplementation from grouse, voles, mice, squirrels, and fox (CWF 2016). Carrion is also a component of the lynx diet (CWF 2016).
Ptarmigan	–	0.09	
Moose	–	0.08	
Caribou	–	0.08

Table J.11 Mallard receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	1.2	Average value from EC (2012), based on Bellrose (1976), with range of 0.5 kg to 1.7 kg.
Water ingestion rate	m^3/d	6.3×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds (consistent with EC 2012 approach.
Food ingestion rate – dry weight basis	g (dw)/d	62	Based on U.S. EPA (1993) allometric equation for all birds (consistent with EC 2012 approach.
Food ingestion rate – wet weight basis	g (ww)/d	308	Applies an assumed moisture content of 80% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	2	Based on Beyer et al. (1994) for mallard 3.3% of dry weight food ingestion; distribution defined by range of body weights (0.5 kg to 1.7 kg) provided in EC (2012). EC (2012) provides an incidental sediment ingestion rate of 2.0-3.3% of dry food ingestion, based on Beyer et al. (1994) and U.S. EPA (1993).
Soil ingestion rate	g (dw)/d	0	Not considered based on feeding habits
Foraging range	km^2	0.09 to 2.4	EC (2012).
Diet Composition:			
Aquatic vegetation	–	0.25	Mallard are dabbling ducks, feeding at or just below the surface of the water. According to EC (2012), laying females consume more animal food (72%) than males and non-laying females. In winter, there is a shift to more green vegetation. Seasonal dietary characteristics provided in U.S. EPA (1993) also illustrate this pattern. Since mallard are assumed to be in the area during the summer breeding season, the diet was assumed to be comprised primarily of benthic invertebrates, which is consistent with the summer season diet in U.S. EPA (1993).
Benthic invertebrates	–	0.75

Table J.12 Common merganser receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics			
Body weight	kg	1.5	Average value provided by EC (2012); range of 0.9 kg to 2.2 kg.
Water ingestion rate	m^3/d	7.8×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds (consistent with EC 2012 approach.
Food ingestion rate – dry weight basis	g (dw)/d	76	Based on U.S. EPA (1993) allometric equation for all birds (consistent with EC 2012 approach.
Food ingestion rate – wet weight basis	g (ww)/d	380	Applies an assumed moisture content of 80% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	1.5	EC (2012) did not identify an incidental sediment ingestion rate for merganser. Based on Beyer et al. (1994) for blue-winged teal and ring-necked duck average value of 2% of dry weight food ingestion.
Soil ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Foraging range	km^2	0.04 to 13.9	Habitat size is variable based on season, location, and habitat suitability (EC 2012).
Diet Composition:			
Fish	–	0.9	Common mergansers are piscivorous birds, primarily consuming fish. According to EC (2012), they will occasionally eat aquatic invertebrates, frogs, small mammals, birds, and plants. The diet composition is consistent with EC (2012).
Aquatic vegetation	–	0.02	
Benthic invertebrates	–	0.08	

References:

Table J.13 American mink receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.82	Average value from EC (2012), with range of 0.57 kg to 1.1 kg.
Water ingestion rate	m^3/d	2.5×10^{-5}	Consistent with EC (2012), based on an adult farm raised female (in U.S. EPA 1993) – 0.03 L/kg BW/day.
Food ingestion rate – dry weight basis	g (dw)/d	39	Calculated using the ww consumption rate in EC (2012) and the 66.2%moisture content of feed specified for the study in U.S. EPA (1993).
Food ingestion rate – wet weight basis	g (ww)/d	116	Based on EC (2012) from the average of farm raised adults (both sexes) (in U.S. EPA 1993) – 0.14 kg wet food/kg BW/day.
Sediment ingestion rate	g (dw)/d	1.9	EC (2012) did not identify an incidental sediment ingestion rate for mink. Based on Beyer et al. (1994) average value for all mammals of 4.8% dry weight food ingestion; distribution defined by range of body weights (0.57 kg to 1.1 kg) provided in EC (2012).
Soil ingestion rate	g (dw)/d	0	Not considered based on feeding habits
Foraging range	km^2	0.06 to 16.3	Based on EC (2012), range is based on adult females and adult males.
Diet Composition:			
Fish	–	0.4	According to EC (2012), the mink diet consists of invertebrates, amphibians, fish, waterfowl and their eggs, mice, voles, rabbits, snakes and aquatic invertebrates. Diet composition is consistent with the dietary properties in EC (2012), with amphibians (10%) attributed to fish (30%), small mammals/birds (25%) attributed to mice, and insects (10%) and crustaceans (25%) attributed to benthic invertebrates.
Mice	–	0.25	
Benthic invertebrates	–	0.35

Table J.14 Deer mouse receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.0217	Average value from EC (2012), with range of 15 g to 41.8 g.
Water ingestion rate	m^3/d	4.1×10^{-6}	EC 2012 provides a rate of 0.19 L / kg BW / d for adults, both sexes.
Food ingestion rate – dry weight basis	g (dw)/d	1.8	Calculated using the ww consumption rate in EC (2012) and an assumed moisture content of 70%.
Food ingestion rate – wet weight basis	g (ww)/d	5.9	EC (2012) provides a rate of 0.27 kg wet food / kg BW / d based on an average of 6 food ingestion rates for adults, both sexes.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	0.04	Based on EC (2012), where it is specified as <2% of dry weight food ingestion.
Foraging range	km^2	0.00012 – 0.004	Varies depending food availability; range from EC (2012).
Diet Composition:			
Terrestrial insects	–	0.5	The deer mouse is omnivorous, feeding on seeds of trees, shrubs and grasses, a wide range of invertebrates, and occasionally fungi (EC 2012). Diet composition is consistent with EC (2012), with ground insects (45%), berries/seeds (30%) attributed to fruits and flowers, grasses (15%) attributed to foliage, mushrooms (5%) attributed to foliage and earthworms (5%) attributed to insects.
Fruits and flowers	–	0.3	
Foliage	–	0.2	

References:

Environment Canada (EC). 2012. Federal Contaminated Sites Action Plan (FCSAP) ecological risk assessment guidance. Module 3: Standardization of wildlife receptor characteristics. Prepared by Azimuth Consulting Group. March.

Table J.15 Muskrat receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics			
Body weight	kg	1.0	Average value from EC (2012), with range of 0.5 kg to 2 kg (U.S. EPA 1993).
Water ingestion rate	m^3/d	1.1×10^{-4}	Based on U.S. EPA (1993) allometric equation for mammals (consistent with EC 2012 approach).
Food ingestion rate – dry weight basis	g (dw)/d	82	Based on EC (2012) from a study of captured males and females fed a natural diet – 0.07 kg dry food/kg BW/day.
Food ingestion rate – wet weight basis	g (ww)/d	410	Applies an assumed moisture content of 80% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	2.7	EC (2012) did not identify an incidental sediment ingestion rate for muskrat. Based on Beyer et al. (1994) value provided for mallard of 3.3% dry weight food ingestion, based on similar feeding habits.
Soil ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Foraging range	km^2	< 0.001 to 0.008	Based on EC (2012), range is variable depending on food availability.
Diet Composition:			
Aquatic vegetation	–	0.8	Consistent with the dietary properties in EC (2012), with other (fish, small animals/birds, salamanders, earthworms) 5% component attributed to benthic invertebrates.
Benthic invertebrates	–	0.2	

References:

Table J.16 Osprey receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	1.7	According to Cornell Lab of Ornithology (2015), osprey range from 1400 g to 2000 g (1.4 kg to 2 kg) body weight. US EPA (1993) reports the weight as 1.2 to 1.9 kg.
Water ingestion rate	m^3/d	7.4×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds (consistent with EC 2012 approach); distribution defined by range of body weights This is consistent with the relationship of 0.052 g/g-d (equivalent to 8.8×10^{-5} m^3/d at the average body weight) reported by U.S. EPA (1993).
Food ingestion rate – dry weight basis	g (dw)/d	72	Based on U.S. EPA (1993) allometric equation for all birds.
Food ingestion rate – wet weight basis	g (ww)/d	362	Applies an assumed moisture content of 80% for food to the dry weight food ingestion rate. This is consistent with the relationship of 0.21 g/g-d (equivalent to 357 g/d at the average body weight) reported by U.S. EPA (1993).
Sediment ingestion rate	g (dw)/d	1.4	Based on Beyer et al. (1994) for piscivorous avian species (ring-necked duck an blue-winged teal) of 2% of dry weight food ingestion
Soil ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Foraging range	km^2	1.7 - 10	U.S EPA (1993) reports a foraging radius of between 1.7 to 10 km.
Diet Composition:			
Fish	–	1.0	The Osprey is the only hawk on the continent that eats almost exclusively live fish (Cornell Lab of Ornithology 2015). This is consistent with US EPA (1993) that reports that osprey are almost completely piscivorous.

Table J.17 Great horned owl receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	1.5	According to CWF (1991), great horned owls body weight range from 1 kg to 1.5 kg for males up to 2 kg for females.
Water ingestion rate	m^3/d	7.7×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds; distribution defined by range of body weights (1 kg to 2 kg) provided in CWF (1991).
Food ingestion rate – dry weight basis	g (dw)/d	75	Based on U.S. EPA (1993) allometric equation for all birds; distribution defined by range of body weights (1 kg to 2 kg) provided in CWF (1991).
Food ingestion rate – wet weight basis	g (ww)/d	250	Applies an assumed moisture content of 70% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	5	Based on Beyer et al. (1994) for average for non-soil/sediment dwelling birds of 6.6% of dry weight food ingestion.
Foraging range	km^2	8 to 10	Based on CWF (1991).Great Horned Owls are found in all forested and semi-forested regions of North, Central, and South America; with no need to make seasonal migrations, these owls are year-round residents of limited hunting ranges of about 8 to 10 km^2 throughout their vast region.
Diet Composition:			
Ptarmigan	–	0.3	Great Horned Owl mainly depend on medium-sized mammals and birds, with rabbits and hares a staple part of the diet (CWF 1991).
Shrew	–	0.2	
Hare	–	0.3	
Mouse	–	0.2

Table J.18 Willow ptarmigan receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.65	Willow ptarmigan range from 450 g to 800 g (0.45 kg to 0.80 kg) body weight (CWF 1994; Cornell Lab of Ornithology 2015).
Water ingestion rate	m^3/d	4.3×10^{-5}	Based on U.S. EPA (1993) allometric equation for birds.
Food ingestion rate – dry weight basis	g (dw)/d	43	Based on U.S. EPA (1993) allometric equation for all birds.
Food ingestion rate – wet weight basis	g (ww)/d	143	Applies an assumed moisture content of 70% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	4.0	Based on Beyer et al. (1994) for turkey 9.3% of dry weight food ingestion.
Foraging range	km^2	0.067 to 0.079	According to CWF (1994), Willow Ptarmigans inhabit treeline areas, arctic valleys, and coastal tundra where vegetation is relatively lush and tall in summer. They like pond edges, streamside thickets, and marshy tundra, which they sometimes share with waterfowl and shorebirds. In late fall, ptarmigans seek more protected areas, moving down slopes or southward into the taller vegetation of dense shrubs and forested areas. Willow Ptarmigans may move well into the treed zone. The size of a willow ptarmigan's territory depends on availability of food and shelter and varies between breeding and winter seasons (Morland 2011). Foraging range is based on a Scandinavian study for males during the breeding season (Morland 2011).
Diet Composition:			
Fruits and flowers	–	0.35	Ptarmigans are foliage gleaners (Cornell Lab of Ornithology 2015). In summer, they sample leaves, buds, flowers, seeds, and berries and also consume mosses and insects and spiders when these are available; in winter they feed on buds, seeds, and twigs (CWF 1994). Dietary composition and breakdown is based on information for quail from U.S. EPA (1993).
Foliage	–	0.50	
Woody vegetation	–	0.15

Table J.19 Masked shrew receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.004	Average value from EC (2012), with range of 2.5 g to 8 g (0.003 kg to 0.008 kg).
Water ingestion rate	m^3/d	8.3×10^{-7}	Based on U.S. EPA (1993) allometric equation for mammals (consistent with EC 2012 approach).
Food ingestion rate – dry weight basis	g (dw)/d	1.5	Consistent with EC (2012), based on U.S. EPA (1993) allometric equation for rodents.
Food ingestion rate – wet weight basis	g (ww)/d	5	Applies an assumed moisture content of 70% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits.
Soil ingestion rate	g (dw)/d	0.036	EC (2012) did not identify an incidental sediment ingestion rate for shrew. Based on Beyer et al. (1994) value provided for meadow vole of 2.4% dry weight food ingestion, based on similar feeding habits.
Foraging range	km^2	0.006	Based on EC (2012).
Diet Composition:			
Terrestrial Insects	–	0.95	Consistent with the dietary properties in EC (2012), with insects and larvae (65%) grouped with slugs, snails, and earthworms (30%) attributed to terrestrial insects and other (amphibians, small mammals, vegetation) (5%) attributed to foliage.
Foliage	–	0.05

Table J.20 Barn swallow receptor characteristics

Parameter	Units	Value	Reference and Discussion
Characteristics:			
Body weight	kg	0.0187	Average value from EC (2012), based on Brown and Brown (1999), with range of 18.1 g.to 19.2 g.
Water ingestion rate	m^3/d	4.1×10^{-6}	Based on U.S. EPA (1993) allometric equation for birds (consistent with EC 2012 approach.
Food ingestion rate – dry weight basis	g (dw)/d	4.9	Based on U.S. EPA (1993) allometric equation for passerine birds.
Food ingestion rate – wet weight basis	g (ww)/d	12.3	Applies an assumed moisture content of 60% for food to the dry weight food ingestion rate.
Sediment ingestion rate	g (dw)/d	0	Not considered based on feeding habits
Soil ingestion rate	g (dw)/d	0.45	EC (2012) did not identify any soil ingestion rate. Value is based on Beyer et al. (1994) for turkey of 9.3% of dry weight food ingestion (expected to be conservative).
Foraging range	km^2	2	The barn swallow is migratory. The foraging range is from EC (2012) indicates and it is expected to forage between 0.5 km and 1.2 km linear distance from nest site.
Diet composition:			
Insects	–	1.0	As discussed in EC (2012) barn swallows are almost exclusively insectivorous, hawking insects (e.g., flies, moths, butterflies, dragonflies, and beetles) during flight over open land and water habitats Many of the insects hawked aerially may have had an aquatic life stage. Berries and seeds are only reported as being used occasionally (1%). The main insect groups are Diptera (COSEWIC 2011).

ECOLOGICAL EXPOSURE ASSESSMENT

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX K: ECOLOGICAL EXPOSURE ASSESSMENT

K.1 Qualitative Assessment

K.1.1 Soil

The initial screen to identify constituents of potential concern (COPC) in soil for the ecological risk assessment (ERA) was described in detail in Appendix D. The result of the screening process for soils identified that, from consideration of all the soil data at the Giant Mine, antimony, arsenic, copper, lead, manganese, vanadium, and zinc were COPC.

To determine which COPC will be carried through for a more detailed evaluation, a qualitative assessment by comparing the measured concentrations of antimony, arsenic, copper, lead, manganese, vanadium, and zinc in each of the four quadrants of the site selected for assessment to the ecological component of the residential/parkland soil quality guidelines from the Canadian Council of Ministers of the Environment (CCME 2017). Since no specific ecological component value was available for antimony, the ecological component from the Ontario Ministry of the Environment and Climate Change (MOECC; formerly Ontario Ministry of the Environment [MOE]) for residential/parkland/institutional land use was used (MOE 2011); this value is consistent with the overall CCME soil quality guideline for antimony. The MOECC values are based on a similar land use and are derived in a comparable manner and are, therefore, deemed appropriate for use. No appropriate value was found for manganese. If the soil concentrations were below the ecological component of the guideline, the COPC was not considered further. A check was also made to background concentrations, and if the concentration was below background, then the COPC was not considered further. The development of background concentrations is discussed in Appendix C.

Since there is a large dataset of information (much greater than 10 samples), the 95% Upper Confidence Limit of the Mean (95% UCLM) was used in the qualitative assessment to represent a reasonable maximum exposure. The UCLM was obtained using ProUCL. ProUCL is a statistical program that provides 95% UCLM recommendations (based on data distribution, data set size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate. It is noted that the CCME (2016) suggest that the BCA bootstrap approach from ProUCL can be used for the majority of datasets.

The summary statistics for the four quadrants are provided in the following tables (Table K.1 for Trapper Lake North, Table K.2 for West of Baker Creek, Table K.3 for East of Baker Creek, and Table K.4 for South Baker Creek).

Table K.1 Summary of concentrations of COPC in the soils in Trapper Lake North

COPC	N	N < MDL	Soil Concentration (mg/kg)								
			Min	Max	Avg.	SD	GM	95th Perc.	95% UCLM	Ecological Component [a]	Back
Antimony	61	0	0.94	165	29	31	18	92	36	20	2.2
Arsenic	66	0	35	3600	537	677	305	1475	667	17	94

Manganese	141	0	36.4	9400	960	1512	458	4600	1159	--	165
Vanadium	108	5	4.4	210	49	39	35	120	57	130	75
Zinc	138	3	7.5	800	119	113	87	323	133	200	137

Note: N – Number of samples; MDL – Method Detection Limit; Avg. – Arithmetic Average; GM – Geometric Mean; 95th Perc. – 95th percentile; UCLM – Upper Confidence Limit of Mean.
a – Ecological component of the Canadian Council of Ministers of the Environment (CCME 2017) residential/parkland land use guideline supplemented by the Ontario Ministry of the Environment and Climate Change (MOE 2011) soil quality guideline component if CCME value unavailable. The component values for antimony is from the MOE (2011).
COPC in bold are where the 95% UCLM is above the ecological component value.

The Federal Contaminated Sites Action Plan guidance manual (FCSAP 2012) supports the use of alternative statistics for assessment of mobile receptors and suggests the use of a maximum concentration as a conservative default for immobile receptors (such as vegetation). A 95% UCLM was used in the qualitative assessment as each of the quadrants is of sufficient size to support a population of receptors including vegetation and small mammals, and there is a significant amount of data available in each of the quadrants. In Trapper Lake North, there are approximately 60 samples; for the other quadrants, there are over 100 samples available. As seen from these tables, arsenic and antimony exceed the ecological component value in each of the quadrants. Manganese is also highlighted in each of the quadrants due to a lack of an appropriate comparison value. Copper is selected in all quadrants except West of Baker Creek. Zinc was only identified in one quadrant, East of Baker Creek. Lead and vanadium were not identified as exceeding the ecological component in any of the quadrants. In most of the quadrants vanadium and zinc are close, or even below, background.

Based on the qualitative analysis on the soils, concentrations of lead and vanadium are below guidelines and, thus, do not represent a risk from an ERA perspective. Arsenic, antimony, copper, manganese, and zinc are considered in the quantitative analysis.

K.1.2 Surface Water

The initial screen to identify COPC in surface water for the ERA was described in detail in Appendix D and summarized in Table K.5. The ecological surface water COPC screen was completed to identify COPC in both Baker Creek and Yellowknife Bay for aquatic biota (i.e., for the ERA).

The results showed that in Yellowknife Bay, the COPC that were carried forward include antimony, arsenic, barium, potassium, and strontium. Although the arsenic concentrations in Back Bay/Yellowknife Bay are below the CCME water quality for the protection of aquatic life, it has been added to the COPC list as it is the major contaminant from the Giant Mine. In Baker Creek, antimony, arsenic, barium, cadmium, chloride, cobalt, copper, cyanide, iron, potassium, strontium, and sulphate were selected as COPC.

Table K.5 Summary of initial list of constituents of potential concern for the ecological risk assessment in the aquatic environment

Surface Water/Sediment	
Yellowknife Bay	**Baker Creek**
Antimony Arsenic Barium Chromium (*sed) Copper (*sed) Potassium Strontium	Antimony Arsenic Barium Cadmium Chloride Chromium (*sed) Cobalt Copper Cyanide Iron Lead (*sed) Mercury (*sed) Potassium Strontium Sulphate Zinc (*sed)

Note: Arsenic in Yellowknife Bay was measured below the guidelines for protection of aquatic life but was retained due to community concerns; *sed – identified based on the sediment screen only.

Additional screening steps were carried out as described below to finalize the COPC to be quantitatively evaluated in the ERA.

Barium, Potassium, and Strontium

While there were no guidelines available for barium, potassium, and strontium, other toxicity values were available and were used to determine whether these three COPC should be considered further. For barium, the British Columbia Ministry of Environment (BCMOE 2017) has a working water quality guideline of 1 mg/L which is considered to be appropriate to use for this situation. The maximum measured concentration of barium in Baker Creek was 0.09 mg/L and in Yellowknife Bay was 0.05 mg/L which are below the working water quality guideline of 1 mg/L and thus barium was not considered further.

For potassium, a site-specific water quality objective of 41 mg/L was developed for potassium for the EKATI diamond mine (Rescan 2012), following the same species sensitivity distribution (SSD) approach that the CCME uses to develop surface water quality guidelines. As such, this value was considered appropriate at this stage of the screening process. The maximum measured concentration of potassium in Baker Creek was 14.1 mg/L and in Yellowknife Bay was 1.3 mg/L, which are below the water quality objective of 41 mg/L, and, thus, potassium was not considered further.

Similarly, for strontium a value of 10.7 mg/L from McPherson et al. (2014), which was based on an SSD curve for chronic exposure, was considered appropriate to use at this stage of the screening process. The maximum measured concentration of strontium in Baker Creek was 4.85 mg/L and in Yellowknife Bay was 0.14 mg/L, which are below the value of 10.7 mg/L, and, thus, strontium was not considered further.

Baker Creek - Cadmium, Cobalt and Cyanide

An additional review of the surface water data in Baker Creek was carried out for cadmium, cobalt, and cyanide as more than 78% of the measurements were below detection limits. A comparison was completed of concentrations of these COPC upstream of Baker Creek (Reach 8 to 11 considered to be representative of the baseline condition entering the site) and the rest of Baker Creek which have inputs from the effluent treatment plant as well as runoff from the site. Student t-tests were conducted to determine whether the data sets were different. The results of the t-tests indicated that the concentrations of cadmium, cobalt and cyanide in the upper reaches of Baker Creek are the same as those in the lower reaches and thus seems not to be influenced from the portions of the site where the remediation activities will be undertaken and therefore these COPC were dropped from further consideration in surface water.

Baker Creek - Copper

Copper was identified as a COPC since the 95th percentile concentration was below the average background copper concentration from Yellowknife River and Yellowknife Bay. Since there is an upstream input to Baker Creek, baseline concentrations were developed based on measured data from SNP 43-11 which is upstream of the site workings. This upstream input may have been historically influenced by activities at the Giant Mine; however, it is considered to now represent the baseline conditions entering Baker Creek on the Giant Mine. The baseline copper concentration has been derived as 0.007 mg/L based on the 95% UCLM of 21 samples at SNP 43-11. The 95% UCLM concentration for copper of the 289 samples collected in Baker Creek downstream of the baseline station is 0.006 mg/L which is below this baseline value and thus copper in surface water is not considered further.

Baker Creek - Iron

A comparison was completed of the concentrations of iron upstream of Baker Creek (Reach 8 to 11 are considered to be representative of the baseline condition entering the site) and the rest of Baker Creek that have inputs from the effluent treatment plant as well as runoff from the site. A Student's t-test was conducted to determine whether the data sets were different. The results of the t-tests indicated that the concentrations of iron in the upper reaches of Baker Creek are the same as those in the lower reaches and, thus, is not to be influenced from the portions of the site where the remediation activities will be undertaken; therefore, iron was dropped from further consideration in surface water.

Sulphate

When the effluent is flowing within Baker Creek, the concentrations of sulphate range from approximately 200 mg/L to 1200 mg/L. These concentrations are above the applicable BCMOE water quality guideline and, thus, sulphate is identified as a COPC in Baker Creek under current conditions. When the effluent is not flowing within Baker Creek, the sulphate concentration ranges between 3 mg/L and 12 mg/L, which are below the B.C. water quality guideline; thus, sulphate will not be considered as a COPC in Baker Creek in the future scenario when the effluent from the water treatment plant is relocated to the vicinity of Reach 0 in Yellowknife Bay. Sulphate levels entering Yellowknife Bay from the location of the new effluent treatment plant are considered in the future scenario.

Chloride

When the effluent is flowing within Baker Creek, the concentrations of chloride range from approximately 69 mg/L to 496 mg/L. These concentrations are above the applicable CCME water quality guideline and, thus, chloride is identified as a COPC in Baker Creek under current conditions. When the effluent is not flowing within Baker Creek, the chloride concentration ranges between 2 mg/L and 4.3 mg/L, which are below the CCME water quality guideline; thus, chloride will not be considered as a COPC in Baker Creek in the future scenario when the effluent from the water treatment plant is relocated to the vicinity of Reach 0 in Yellowknife Bay. Chloride levels entering Yellowknife Bay from the location of the new effluent treatment plant are considered in the future scenario.

K.1.3 Sediment

Mercury

The sediment screen in Appendix D indicated that the 95% UCLM concentrations in sediments in Baker Creek exceeded the interim sediment quality guideline (ISQG) from the CCME; however, the average mercury concentration of 0.19 mg/kg is close to the ISQG of 0.17 mg/kg. Mercury was not selected as a COPC from the surface water screen since the concentrations in Baker Creek are below aquatic protection guidelines. It should be noted that mercury has not been used in the Giant Mine process since 1948, and mercury concentrations at the Giant Mine are within background concentrations. Additionally, concentrations of mercury in fish in Yellowknife Bay are similar to background concentrations, indicating that mercury is not biomagnifying in the aquatic environment. Nonetheless, mercury is considered to be a COPC in the sediment in Baker Creek.

K.1.4 Summary

A qualitative assessment was carried out for the concentrations of the COPC in the terrestrial and aquatic environments. This qualitative assessment involved the comparison of concentrations to ecological guidelines and/or background. The final list of COPC for the Giant Mine ERA is provided in Table K.6.

Table K.6 Summary of final list of constituents of potential concern for the ecological risk assessment

Soil	Surface Water/Sediment	
ERA	**Yellowknife Bay – ERA**	**Baker Creek - ERA**
Antimony Arsenic Copper Manganese Zinc	Antimony Arsenic Chromium (*sed) Copper (*sed) Chloride (future only) Sulphate (future only)	Antimony Arsenic Cadmium (*sed) Chloride Chromium (*sed) Copper (*sed) Lead (*sed) Mercury (*sed) Sulphate Zinc (*sed)

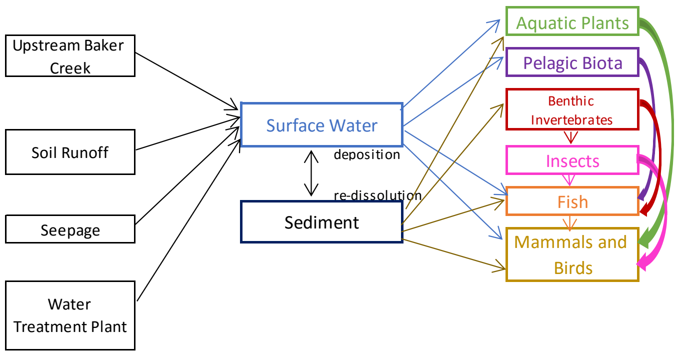
Note: Arsenic in Yellowknife Bay was measured below the guidelines for protection of aquatic life but was retained due to community concerns; *sed – identified based on the sediment screen only.

K.2 Conceptual Site Model

A conceptual site model (CSM) was developed that shows the relationships between the contaminants, fate and transport processes, receptors, and pathways (aquatic environment and terrestrial environment in Figure K.1 and Figure K.2, respectively).

This is an integration of the information on contaminants, receptors, pathways, and site conditions.

Figure K.1 Box diagram of conceptual site model for the ecological risk assessment – aquatic environment



Exposure Pathway	Water Column Organisms	Benthic Invertebrates	Fish	Herbivorous Birds and Mammals[(a)]	Insectivorous Birds and Mammals[(b)]	Piscivorous Birds and Mammals[(c)]

K.3 Site-Specific Transfer Factors

The concentrations of COPC in biota including plants, aquatic biota, and small mammal were estimated by assuming that the concentration in the biota could be predicted from the concentration in soil, water, or sediment (as appropriate). This is a simplistic approach that amalgamates the many factors that affect contaminant uptake into a single value. These factors can be called different names, such as Concentration Ratio (CR), Bioaccumulation Factor (BAF), or Bioconcentration Factor (BCF); for this assessment the generic term Transfer Factor (TF) is used.

As there are many factors that affect the uptake of a contaminant, site-specific information is preferred. There is site-specific information available on some media (e.g., fish); however, some data gaps were identified. To support the risk assessment, information was collected on soil, sediment, water, vegetation, and small mammals from the Giant Mine site (Golder 2016a). These samples were co-located (i.e., soil and small mammals were collected from the same area) to facilitate the development of TFs. The memo discussing this program is provided as Attachment 1 of Appendix B.

The available data were summarized and are shown in the following sections. Generally, two types of uptake relationships were considered:

- A linear relationship where the ratio between the concentration in the biota and the media is provided (i.e., ratio of the concentration in terrestrial plant to the ratio in a co-located soil sample).
- The data were also ln-transformed and a log-linear relationship developed.

Derivation of the site-specific TFs is detailed in the following sections.

K.3.1 Goodness of Fit

The selection of which TF should be selected for the assessment used a visual evaluation of the results in conjunction with a statistical evaluation of the predictions. There are several statistical tests available, each with strengths and weaknesses that can be used to judge the appropriateness of the predicted concentrations compared to measured data. Two statistical tests were employed to assess the goodness of fit between model predictions and measured data: the R2 statistic and fractional bias test. The use of two statistical tests helps to address the disadvantages identified in each of the tests.

The coefficient of determination (or R2 statistic) of a dataset reflects how well the observed values are replicated by the predicted values and uses linear regression to assess this relationship. R2 values are between 0 and 1, with a value of 1 indicating perfect replication of the observed values by the model. However, the R2 statistic does not provide a statistical hypothesis test of the measure of the goodness of fit between the model predictions and observed data. The R2 statistic was calculated using the Excel function (RSQ).

The fractional bias test (U.S. EPA 1992) calculates the averages of observed (OB) and predicted (PR) values, using Equation K-1:

$$FB=2\times((PR\text{-}OB)/(PR+OB)) \qquad \text{(K-1)}$$

The fractional bias was selected as a measure of the performance in this evaluation because it has two desirable features. First, the fractional bias is symmetrical and bounded; values for the fractional bias range between –2.0 (extreme underprediction) and +2.0 (extreme overprediction). Second, the fractional bias is a dimensionless number which is convenient for comparing the results from studies involving different concentration levels. Values of the fractional bias that are equal to +0.67 are equivalent to overprediction by a factor of two, while values that are equal to –0.67 are equivalent to underprediction by a factor of two. Model predictions with a fractional bias of 0 (zero) are relatively free from bias. However, a disadvantage of the fractional bias test is that if the model both over and under predicts during the calibration period, the fractional bias value can approach zero (indicating perfect fit) when in fact the fit is not perfect.

The R2 and fractional bias values determined using the measured biota concentration and the predicted concentrations for the same location. In some cases due to a lack of data, the R2 value is not calculated. Test values are less reliable in situations for COPC with concentrations close to background or detection limits, and therefore, these statistical tests are less valuable in those circumstances.

K.3.2 Aquatic Vegetation

For aquatic plants, there can be uptake from sediment (via roots) as well as directly from the water column. Currently, it is expected that these are all generally in equilibrium and, thus, site-specific information was used to derive sediment to aquatic plant TFs. As conditions in the future will change, it was also useful to summarize water to aquatic plant TFs.

In the aquatic environment, TFs are required for antimony and arsenic.

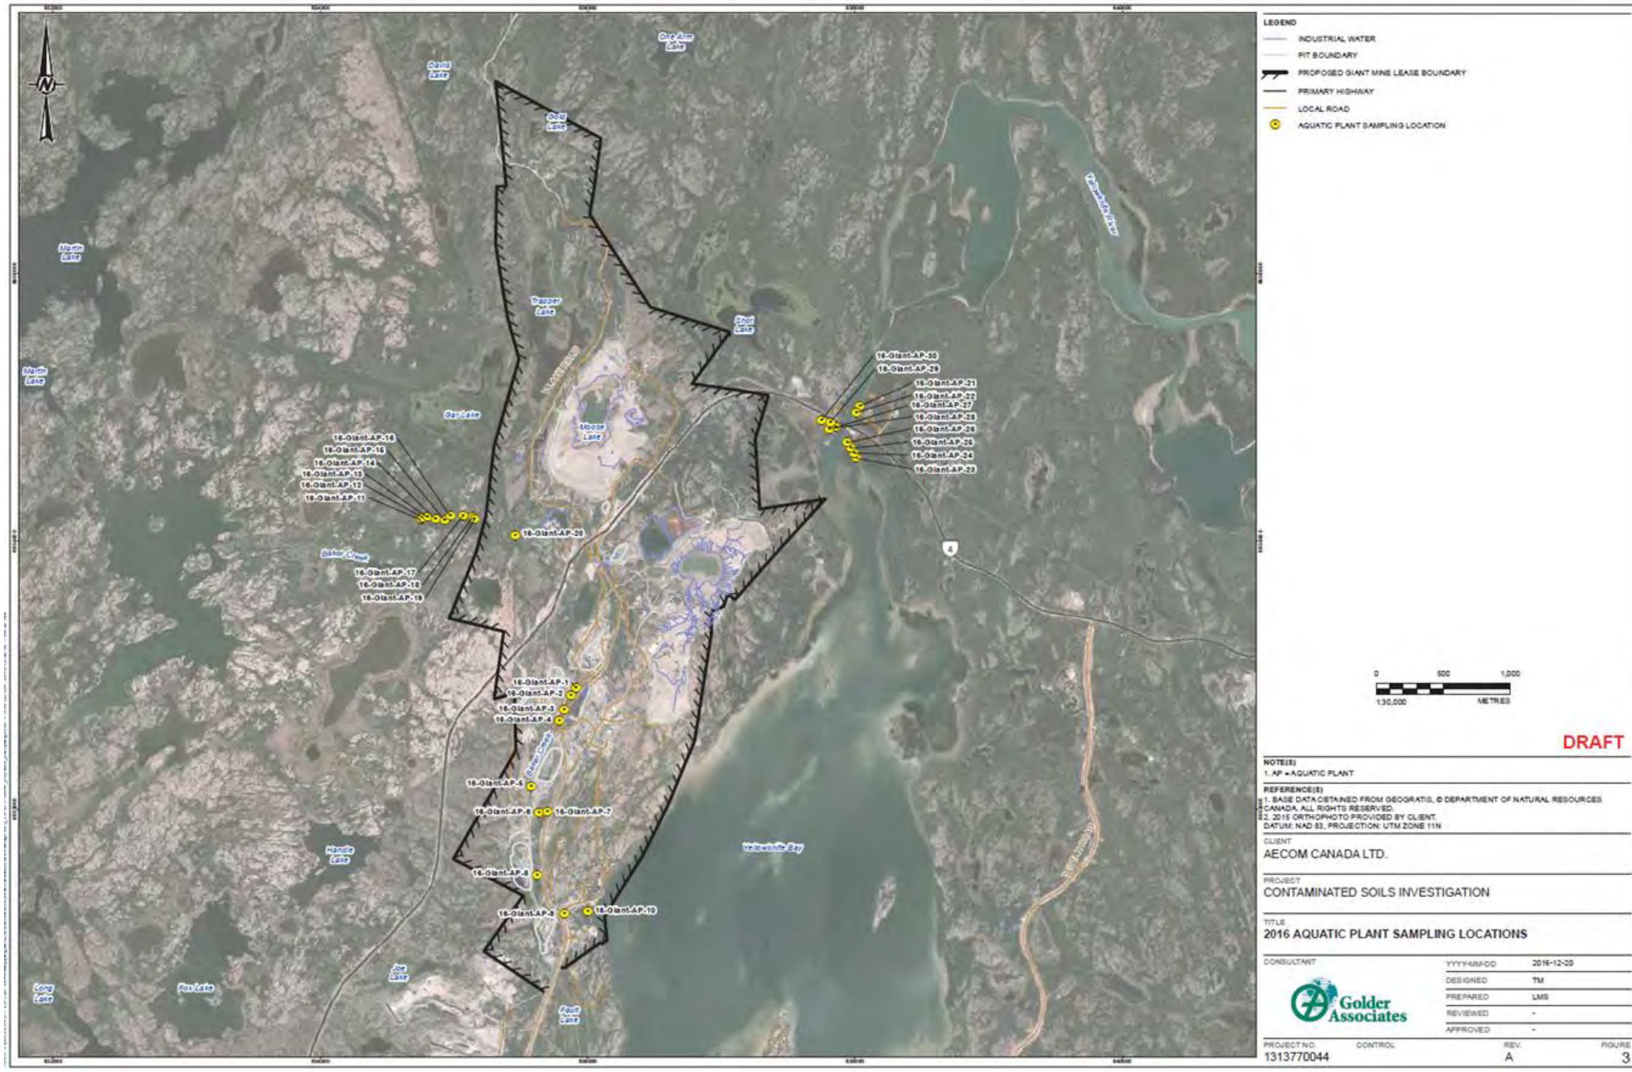
K.3.2.1 TFs from Sediment

As described by Golder (2016a, 2016b) in September 2016, sediment and aquatic plant sampling was conducted at 10 locations (co-located samples) in 3 areas: lower Baker Creek (LBC), upper Baker Creek (UBC), and the Yellowknife River (YKR) (Figure K.3). Aquatic plants and water sedge (*Carex aquatilis*) were collected. Only healthy plant samples were collected (i.e., no visible signs of disease or yellowing).

The results of the analysis were presented by Golder (2016a) and are shown in Figure K.4 for antimony where the data are shown on a linear scale and log-scale. To develop the site-specific TF, all data were combined (Figure K.5). A log-linear equation was selected as the best representation of the relationship (lower fractional bias).

The information for arsenic is presented in Figure K.6 and Figure K.7; similarly, the log-linear relationship was selected (lower fractional bias).

Figure K.3 Locations of aquatic plants and sediments collected for site-specific transfer factors



Note: From Golder (2016a); see Attachment 1 of Appendix B for complete memo.

Figure K.4 Measured aquatic plant and sediment data - antimony

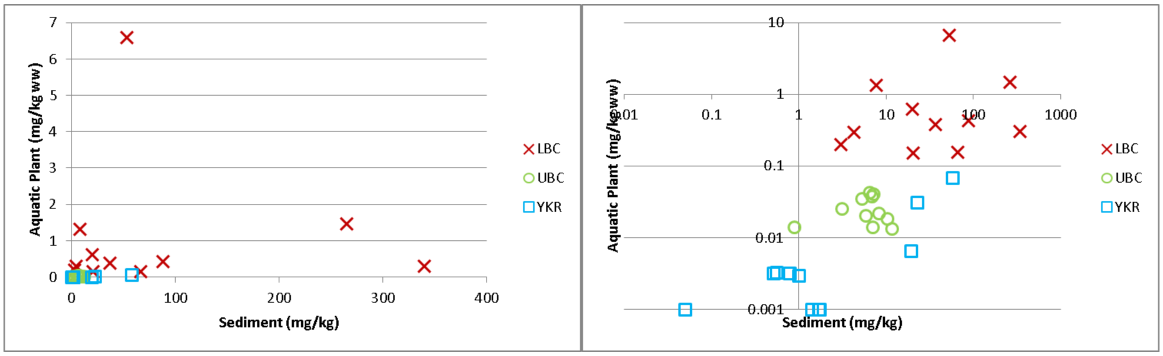


Figure K.5 Site-specific transfer factor for aquatic plants and sediment - antimony

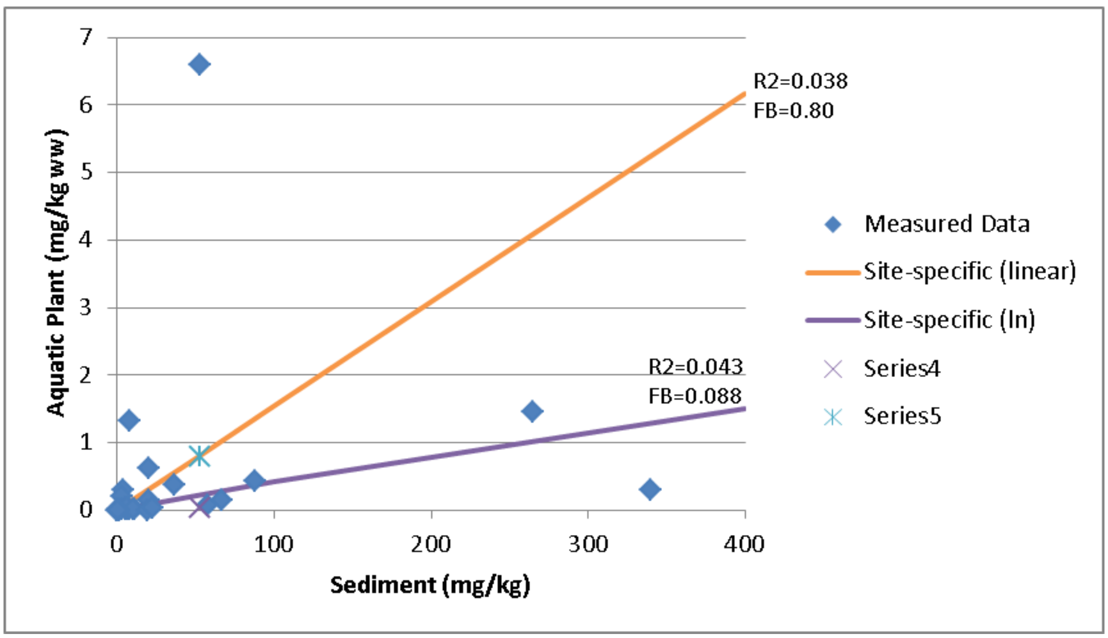

Figure K.6 Measured aquatic plant and sediment data - arsenic

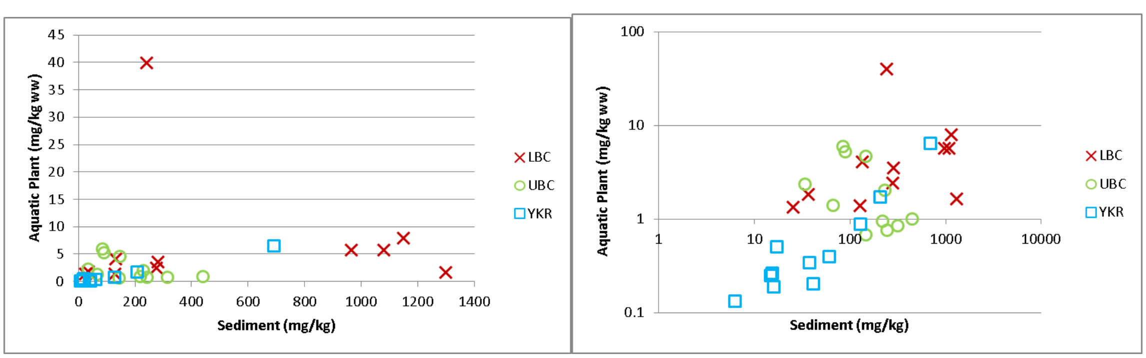

Figure K.7 Site-specific transfer factor for aquatic plants and sediment - arsenic

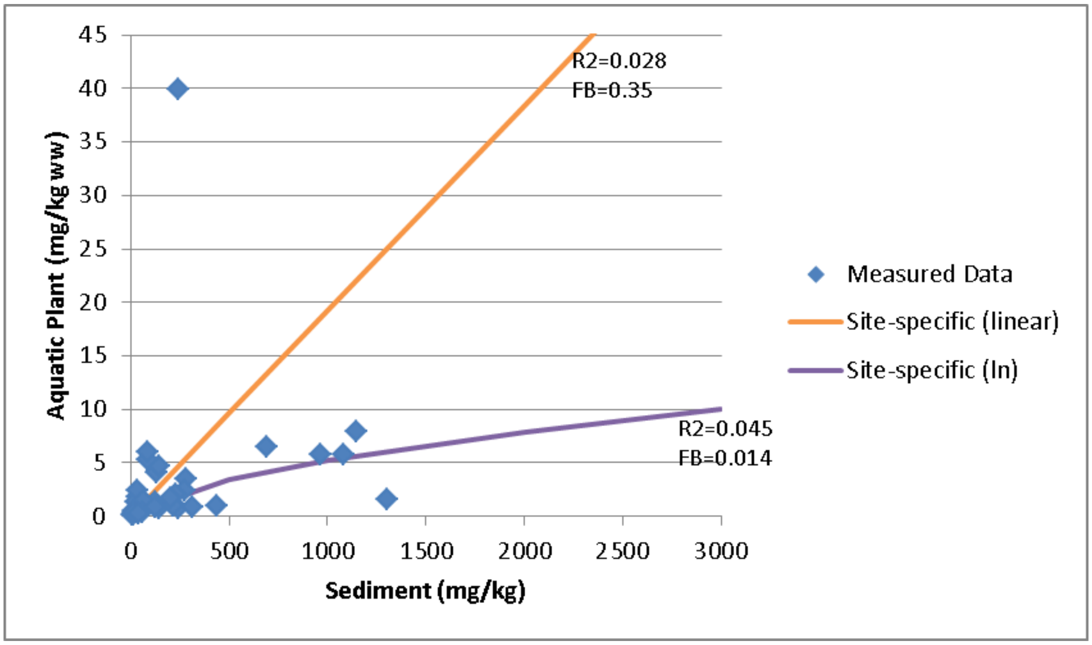


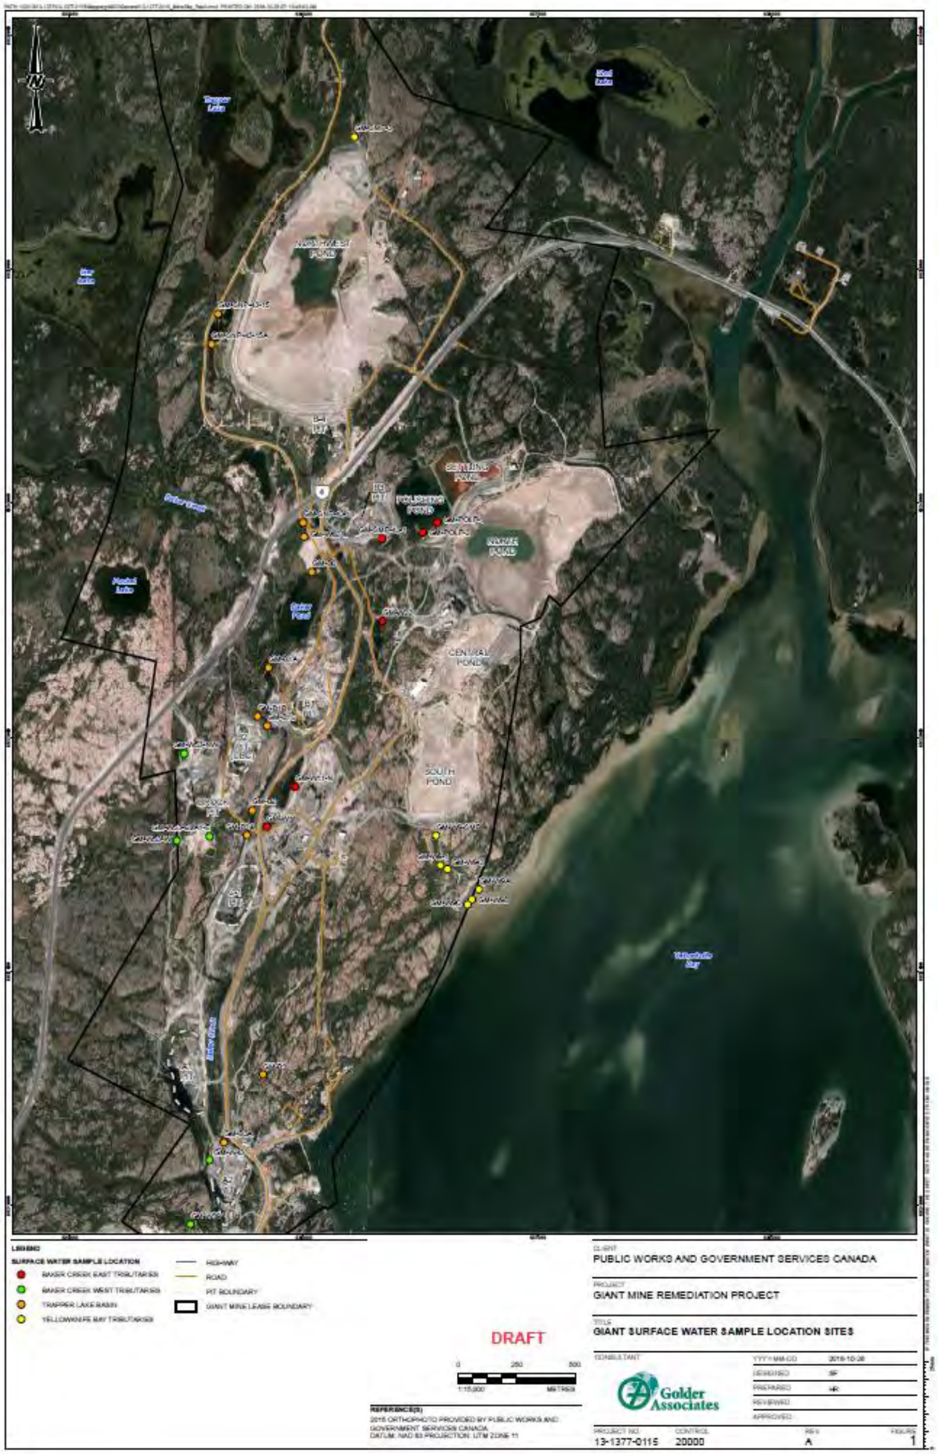
K.3.2.2 TFs from Water

A field investigation at the site was undertaken from August 25th to 30th, 2016, which included sampling for water quality and aquatic plant concentrations (Contango 2016). The locations of the samples are shown in (Figure K.8). Several emergent macrophytes (vascular plants that are rooted underwater but emerge out of the water) were observed, and the study focused on *Carex aquatilis* (commonly known as water sedge) and *Typha latifolia* (commonly known as broadleaf cattail). It was found that arsenic concentrations in water sedge were higher than cattails); however, there were no correlations found between plant uptake of arsenic and water or soil concentrations (Contango 2016). Aquatic moss were also analyzed and found to have much higher concentrations; however, this species is not considered to be relevant from the ecological risk assessment perspective (not consumed by a large degree by the selected receptors) and was, therefore, not considered further.

Figure K.9 shows the relationship between water and aquatic plants (shown on a linear scale and log-scale) for antimony. Figure K.10 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. Although goodness of fit statistics are provided, some of the plants were below detection limiting the usefulness of the statistical test. A linear factor was selected for the assessment. For comparison purposes a value of 1000 L/kg ww from literature (PNNL

2003) was plotted, but the concentrations cannot be seen as the estimated concentrations are too high.

Figure K.8 Locations of aquatic plants and water samples



Note: From Contango (2016).

Figure K.9 Measured aquatic plant and water data - antimony

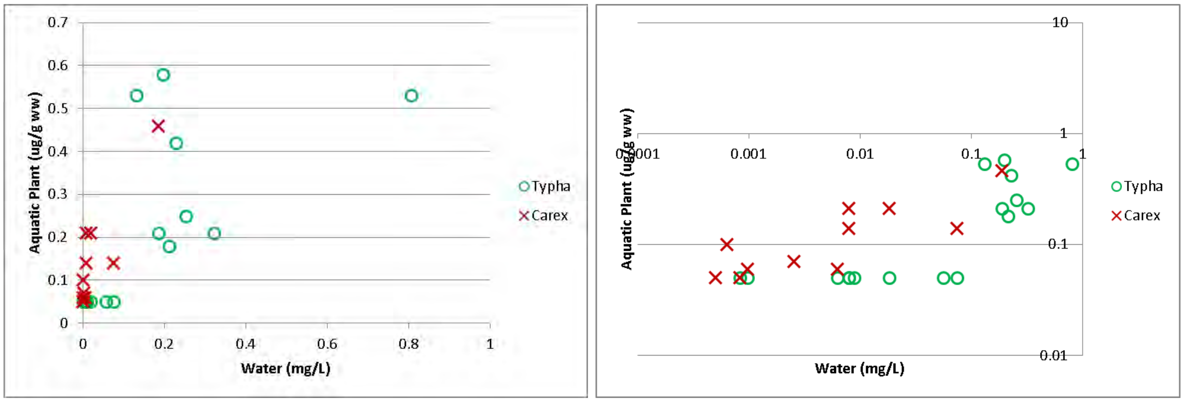


Figure K.10 Site-specific transfer factor for aquatic plants and water - antimony

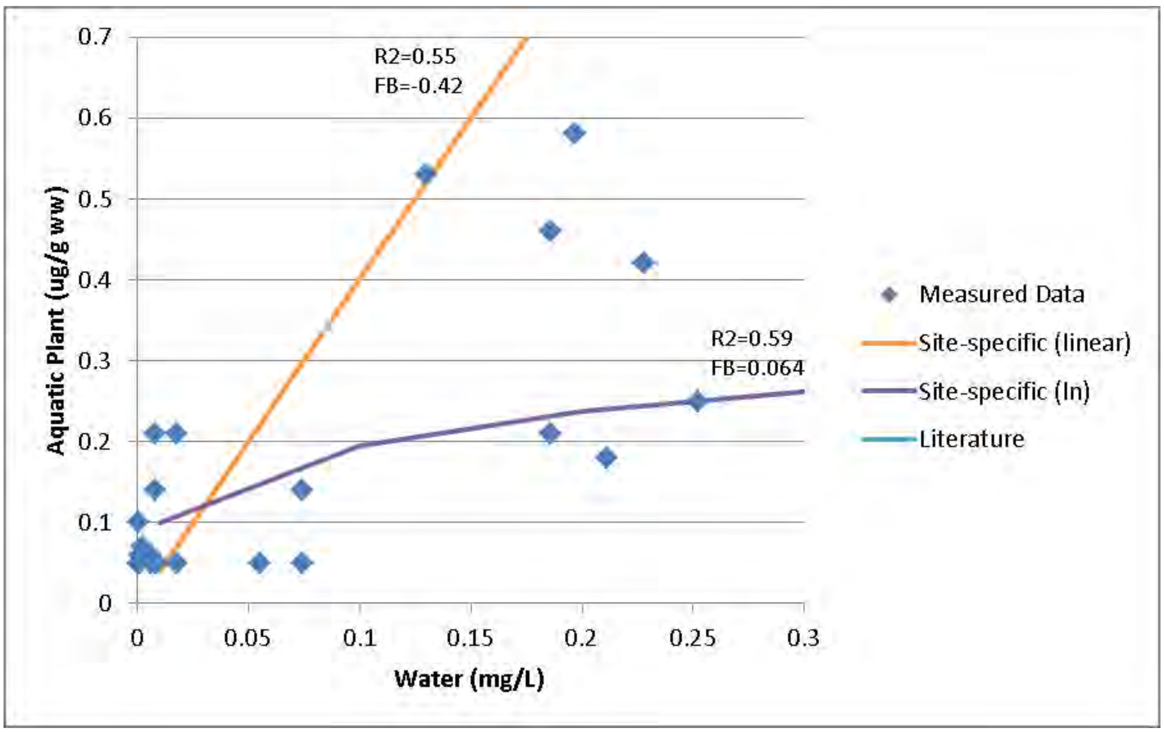

Figure K.11 shows the relationship between water and aquatic plants (shown on a linear scale and log-scale) for arsenic. Some of the water concentrations were quite high, much higher than typical. Due to the fluctuations in water, a longer time record would be appropriate for this analysis. Figure K.12 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. Although the relationship between water and aquatic plants is weak, a linear factor was selected for the assessment. For comparison purposes a value of 300 L/kg ww from literature (PNNL 2003) is also shown.

Figure K.11 Measured aquatic plant and water data - arsenic

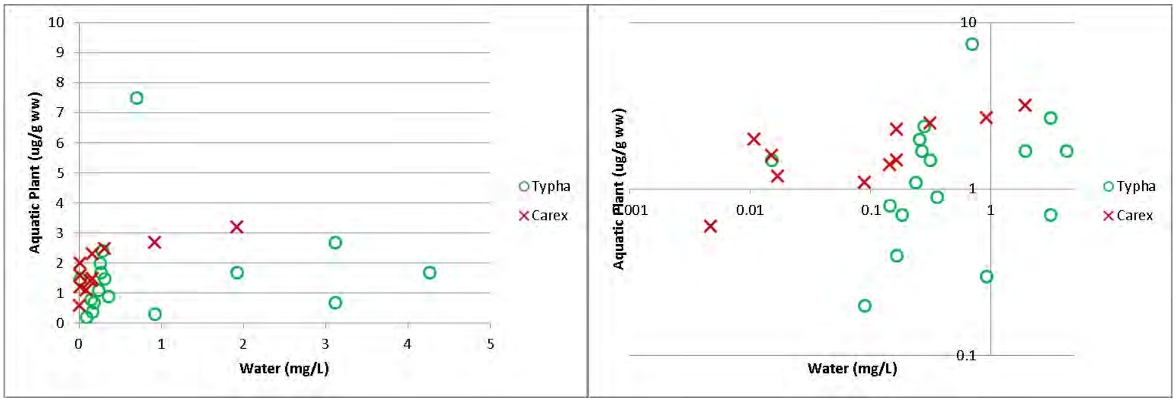

Figure K.12 Site-specific transfer factor for aquatic plants and water - arsenic

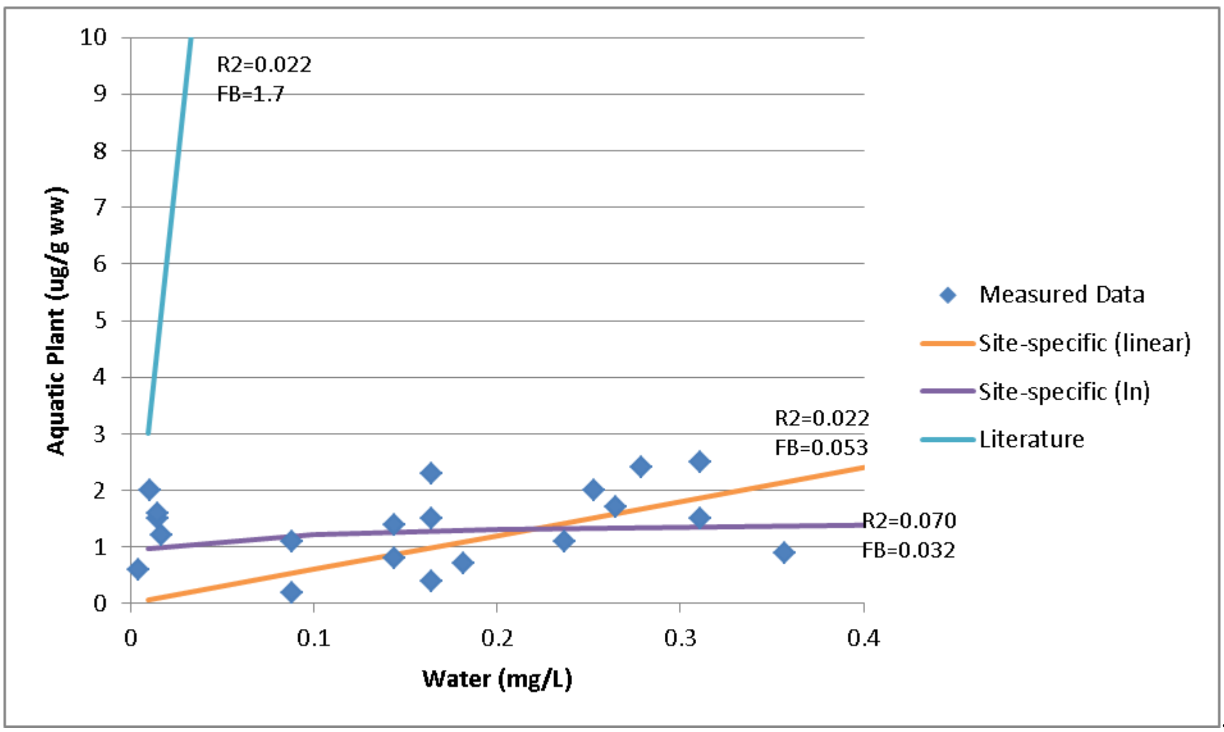


K.3.2.3 Summary

The relationships derived from the site-specific aquatic vegetation data are as follows. For establishing current EPCs, the relationship derived for sediment was used for future conditions, where the water and sediment may not have reached an equilibrium state, the EPCs are derived using the maximum of the transfer from sediment or water.

Antimony: $C_{aqveg} = \exp(0.92*\ln(C_{sed})-5.1)$
$C_{aqveg} = C_{wat} * 4$

Arsenic: $C_{aqveg} = \exp(0.6*\ln(C_{sed})-2.5)$
$C_{aqveg} = C_{wat} * 6$

Where:

C_{aqveg} = Aquatic vegetation COPC concentration (mg/kg (ww))
C_{sed} = Sediment COPC concentration (mg/kg (dw))
C_{wat} = Water COPC concentration (mg/L)

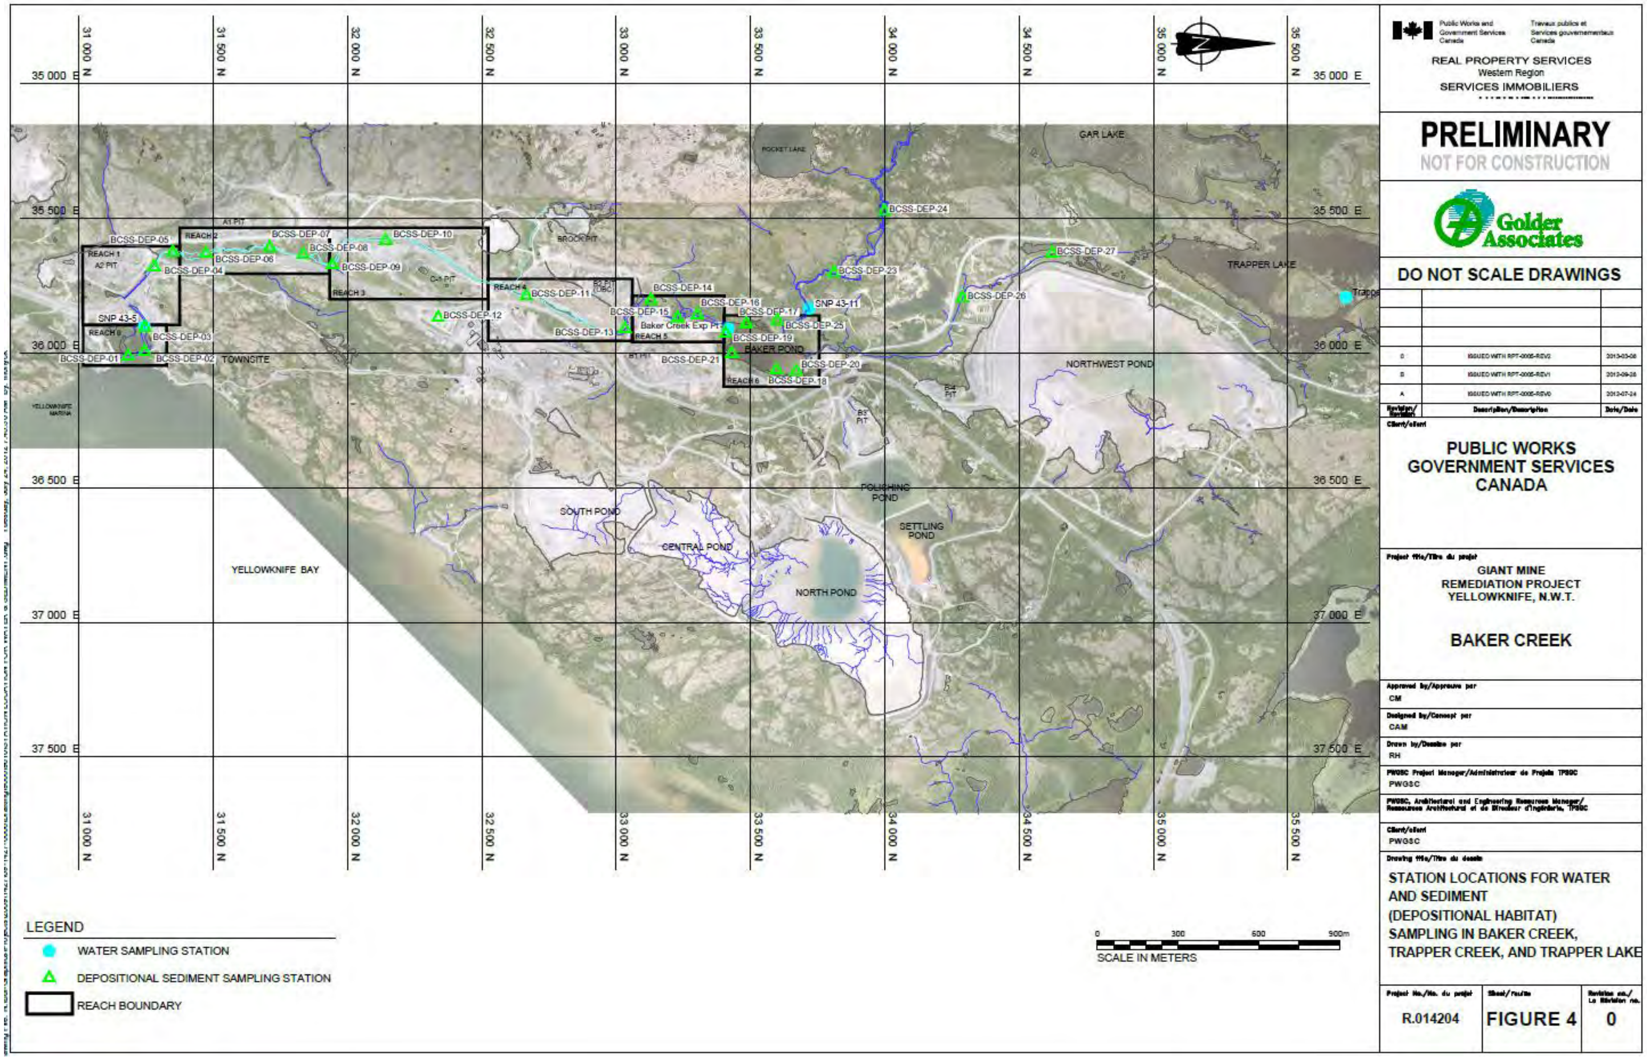
K.3.3 Benthic Invertebrates and Aquatic Insects

The concentration in the tissues of benthic invertebrates was taken to be related to sediment concentration. In the aquatic environment, TFs are required for antimony and arsenic.

K.3.3.1 TFs from Sediment

In 2011, Golder conducted a field study in Baker Creek that included sediment and benthic invertebrates from depositional and erosional habitat stations (Golder 2013). The benthic tissue data were collected to provide a measure of the bioavailability of arsenic and other contaminants to the invertebrate community in Baker Creek. Surficial sediment samples (approximately 5 cm) were collected from the depositional habitat areas; therefore, this dataset was used to determine site-specific transfer factors. One composite sediment sample was collected for at each of the 29 depositional locations. The locations are shown in Figure K.13.

Figure K.13 Locations of benthic invertebrate and sediments used to develop site-specific transfer factors



Note: From Golder (2013).

Figure K.14 shows the relationship between sediment and benthic invertebrates (shown on a linear scale and log-scale) for antimony. Figure K.15 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. A linear factor was selected. For comparison purposes, a value from literature is also shown. Haus et al. (2007) investigated concentrations of various metals, including antimony, in sediments and macroinvertebrates (amphipods and isopods) from several sites in Germany, including ponds, streams, and rivers. The value of 0.0113 is the arithmetic mean of the BSAFs and is reported on a wet weight basis. The site-specific linear value was used in the assessment; this will provide a cautious estimate of the benthic invertebrates.

Figure K.14 Measured benthic invertebrate and sediment data - antimony

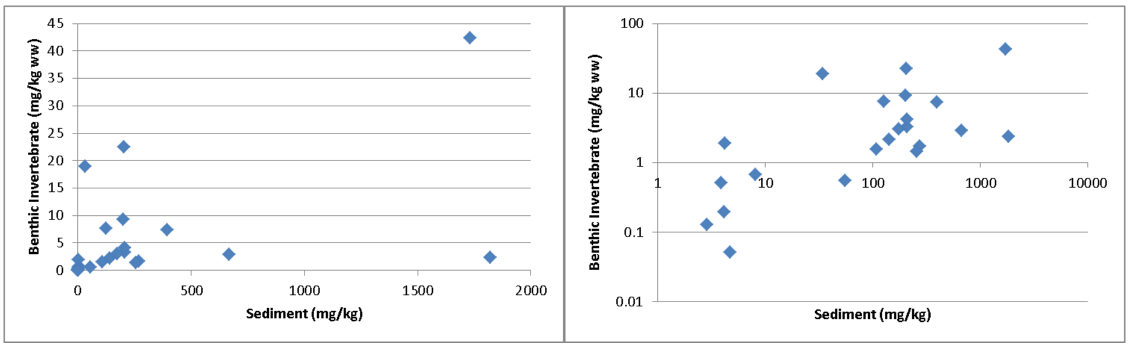


Figure K.15 Site-specific transfer factor for benthic invertebrate and sediment - antimony

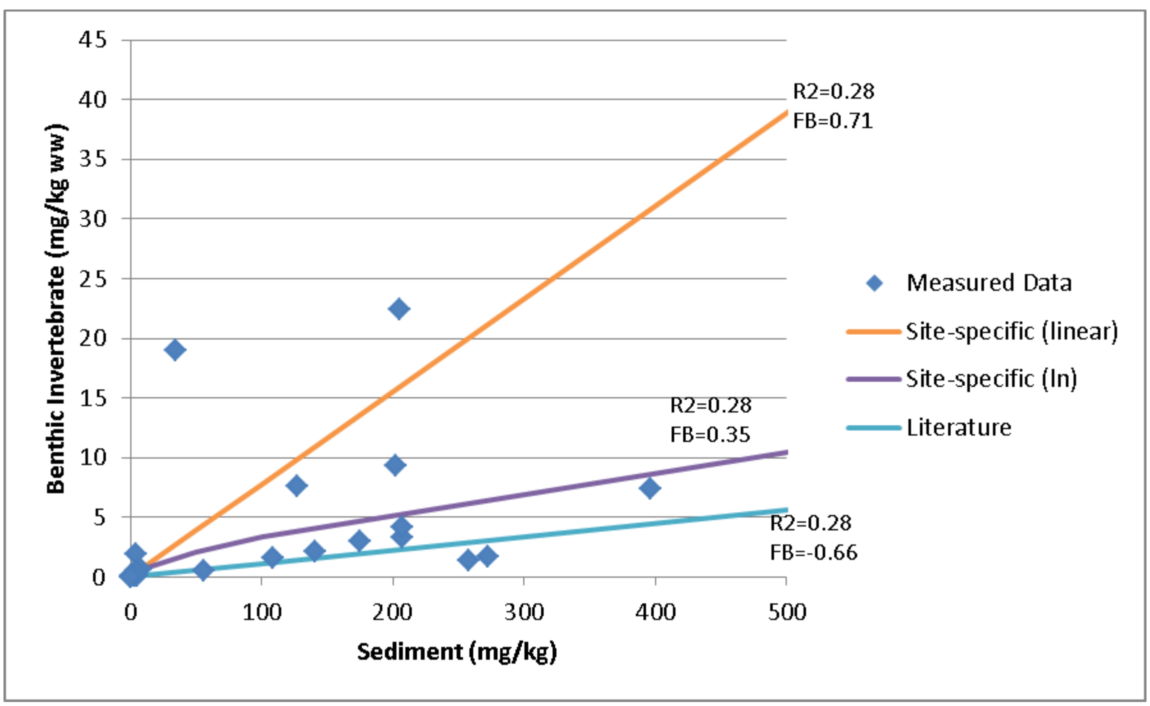

Figure K.16 shows the relationship between sediment and benthic invertebrates (shown on a linear scale and log-scale) for arsenic. Figure K.17 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a value from literature (ORNL 1998) is also shown. As discussed in the ORNL document, the median BSAF for arsenic (non-depurated) is recommended. This value is 0.127 and is provided on a dry weight basis; a 70% moisture content was assumed. The site-specific linear value was used in the assessment.

Figure K.16 Measured benthic invertebrate and sediment data – arsenic

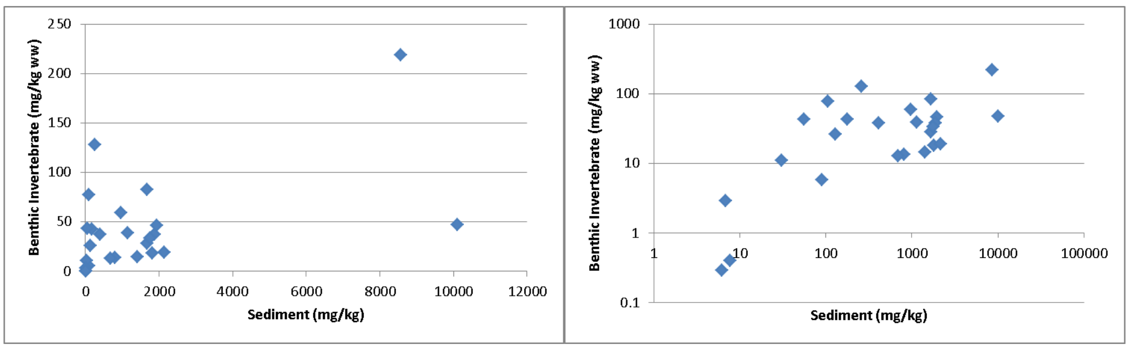

Figure K.17 Site-specific transfer factor for benthic invertebrate and sediment - arsenic

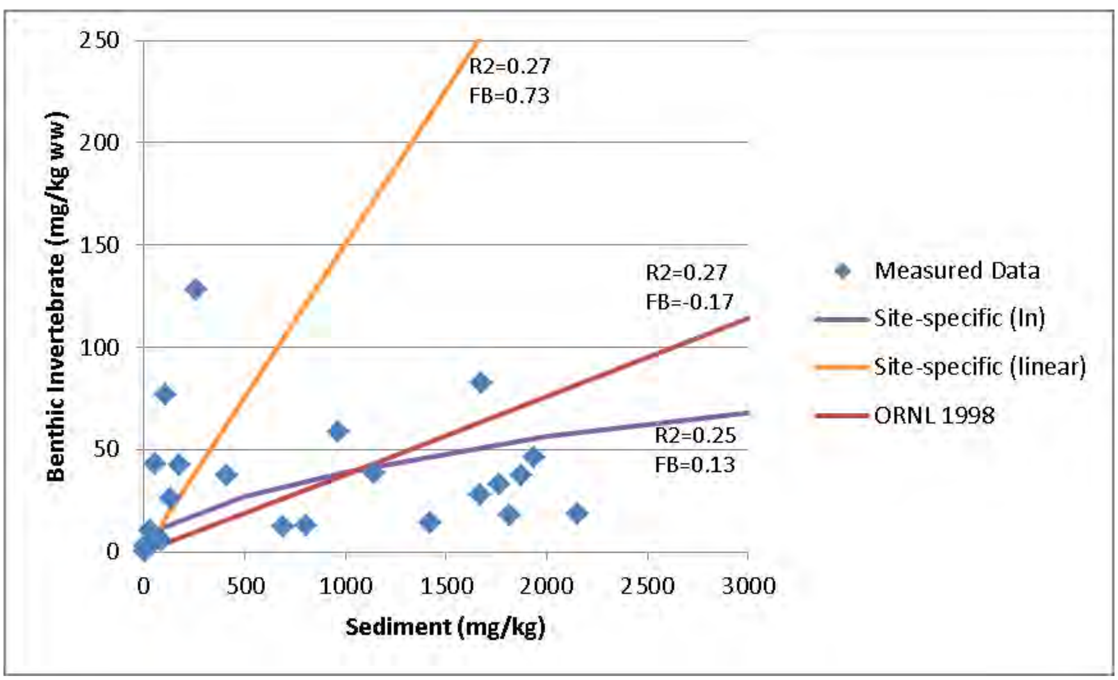


K.3.3.2 Summary

The site-specific relationship between benthic invertebrate concentrations and sediment levels is detailed below.

Antimony: $C_{bi} = C_{sed} * 0.078$
Arsenic: $C_{bi} = C_{sed} * 0.15$

Where:
C_{bi} = Benthic invertebrate COPC concentration (mg/kg (ww))
C_{sed} = Sediment COPC concentration (mg/kg (dw))

Benthic invertebrates comprise the larvae stage of many emergent aquatic flying insects. A paper that examined 39 papers on the change of concentrations (Kraus et al. 2014) found that metals were predominantly lost during metamorphosis. Based on Kraus et al. (2014), it is expected that arsenic is approximately 10x lower in the adult compared to the larvae. Although no specific information on antimony was presented in the paper, it is not unreasonable to assume that antimony would behave similarly, as arsenic and antimony are close chemical analogues. Therefore, for this assessment, the concentration of arsenic and antimony in emergent aquatic insects were set to 0.1 of benthic invertebrates.

K.3.4 Fish

Fish are directly exposed to water and indirectly to water through food as well as sediment through food. Currently, it is expected that these (water, sediment, food for fish) are all generally in equilibrium, and, thus, site-specific information was used to derive sediment to fish TFs. As conditions in the future will change, it was also useful to summarize water to fish TFs.

In the aquatic environment, TFs are required for antimony and arsenic.

K.3.4.1 TFs from Sediment

As part of the 2011 study, Golder collected fish samples for analysis (Golder 2013). Fish were sampled from select reaches in Baker Creek and, where possible, in the Yellowknife River reference area. Three small-bodied fish (arctic grayling, slimy sculpin, and ninespine stickleback) were targeted for whole-body analysis. Large-bodied fish were also sampled but for the purposes of the ecological risk assessment only the whole-body fish data from the small-bodied fish were considered. Arctic grayling are noted to be a migrant fish species that enters Baker Creek in the spring to spawn. Slimy sculpin are resident, benthic fish that live in direct contact with sediment. Ninespine stickleback are omnivorous feeders and are thought to reside in Baker Creek between spring and fall.

Table K.7 shows the measured data for sediment and fish as well as the estimated TF. The average value for the exposure stations (Baker Creek) were used in the assessment.

Table K.7 Sediment and fish data used to derive site-specific transfer factor

Location	Sediment (mg/kg dw)	Fish		TF (kg dw / kg ww)
		Type	Concentration (mg/kg ww)	
Antimony				
Background	0.44	Slimy sculpin	0.0052	0.012
		Ninespine stickleback	0.0088	0.020
Reach 0	171	Ninespine stickleback	0.058	$3.3x10^{-4}$
		Slimy sculpin	0.17	0.0010
Reach 1	188	Arctic grayling	0.55	0.0029
			Average of Exposure Locations	*0.0014*
Arsenic				
Background	6.4	Slimy sculpin	0.070	0.011
		Ninespine stickleback	0.43	0.067
Reach 0	1339	Ninespine stickleback	1.02	$7.6x10^{-4}$
		Slimy sculpin	2.9	0.0021
Reach 1	1410	Arctic grayling	12.3	0.0087
			Average of Exposure Locations	*0.0039*

Note: Sediment and fish data from Golder (2013).

K.3.4.2 TFs from Water

A TF for estimating fish concentrations from water was also required. To estimate this TF, the measured data in Back Bay was used (for whole-body fish and water) as shown in Table K.8. The sediment in Back Bay, however, still contributes to the exposure; thus, the TFs were reduced by a factor of 40. This factor was based on adjusting the TF for arsenic to be consistent with other information sources. For example, a BCF of 14 L/kg for freshwater fish is provided by Oregon Department of Environmental Quality (Oregon DEQ 2011), while BAFs of 11 for sculpin in Kam Lake and 70.6 for sculpin in Grace Lake, NWT were reported in by the U.S. EPA (2003). This is an attempt to isolate the exposure to water and dietary items that would be directly linked to water.

Table K.8 Water and fish data used to derive site-specific transfer factor

COPC	Water (mg/L)	Comment	Fish (mg/kg ww)	Comment	TF * (L/kg)
Antimony	0.0002	Mean of Back Bay and North Yellowknife Bay (N=111, 94<DL).	0.027	Mean of Back Bay and North Yellowknife Bay (N=41).	2.8
Arsenic	0.004	95% UCLM of Back Bay and North Yellowknife Bay (N=117).	1.5	95% UCLM of Back Bay and North Yellowknife Bay (N=41).	19

Note: * TF calculated as the ratio of fish to water, adjusted by a factor of 40 to account for limited pathways.

K.3.4.3 Summary

The site-specific relationship between whole body fish concentrations and COPC levels in sediment and water are as shown below. Both current and future fish EPCs were taken to be the maximum of transfer from sediment or water.

Antimony: $C_{fish} = C_{sed} * 0.0014$

$C_{fish} = C_{wat} * 2.8$

Arsenic: $C_{fish} = C_{sed} * 0.0039$

$C_{fish} = C_{wat} * 19$

Where:

C_{fish} = Whole body fish COPC concentration (mg/kg (ww))

C_{sed} = Sediment COPC concentration (mg/kg (dw))

C_{wat} = Water COPC concentration (mg/L)

K.3.5 Terrestrial Vegetation and Insects

Terrestrial plants are exposed to COPC in soil. The uptake depends on the characteristics of the plant and the soil; therefore, site-specific information is valuable.

In the terrestrial environment, TFs are required for antimony, arsenic, copper, manganese, and zinc.

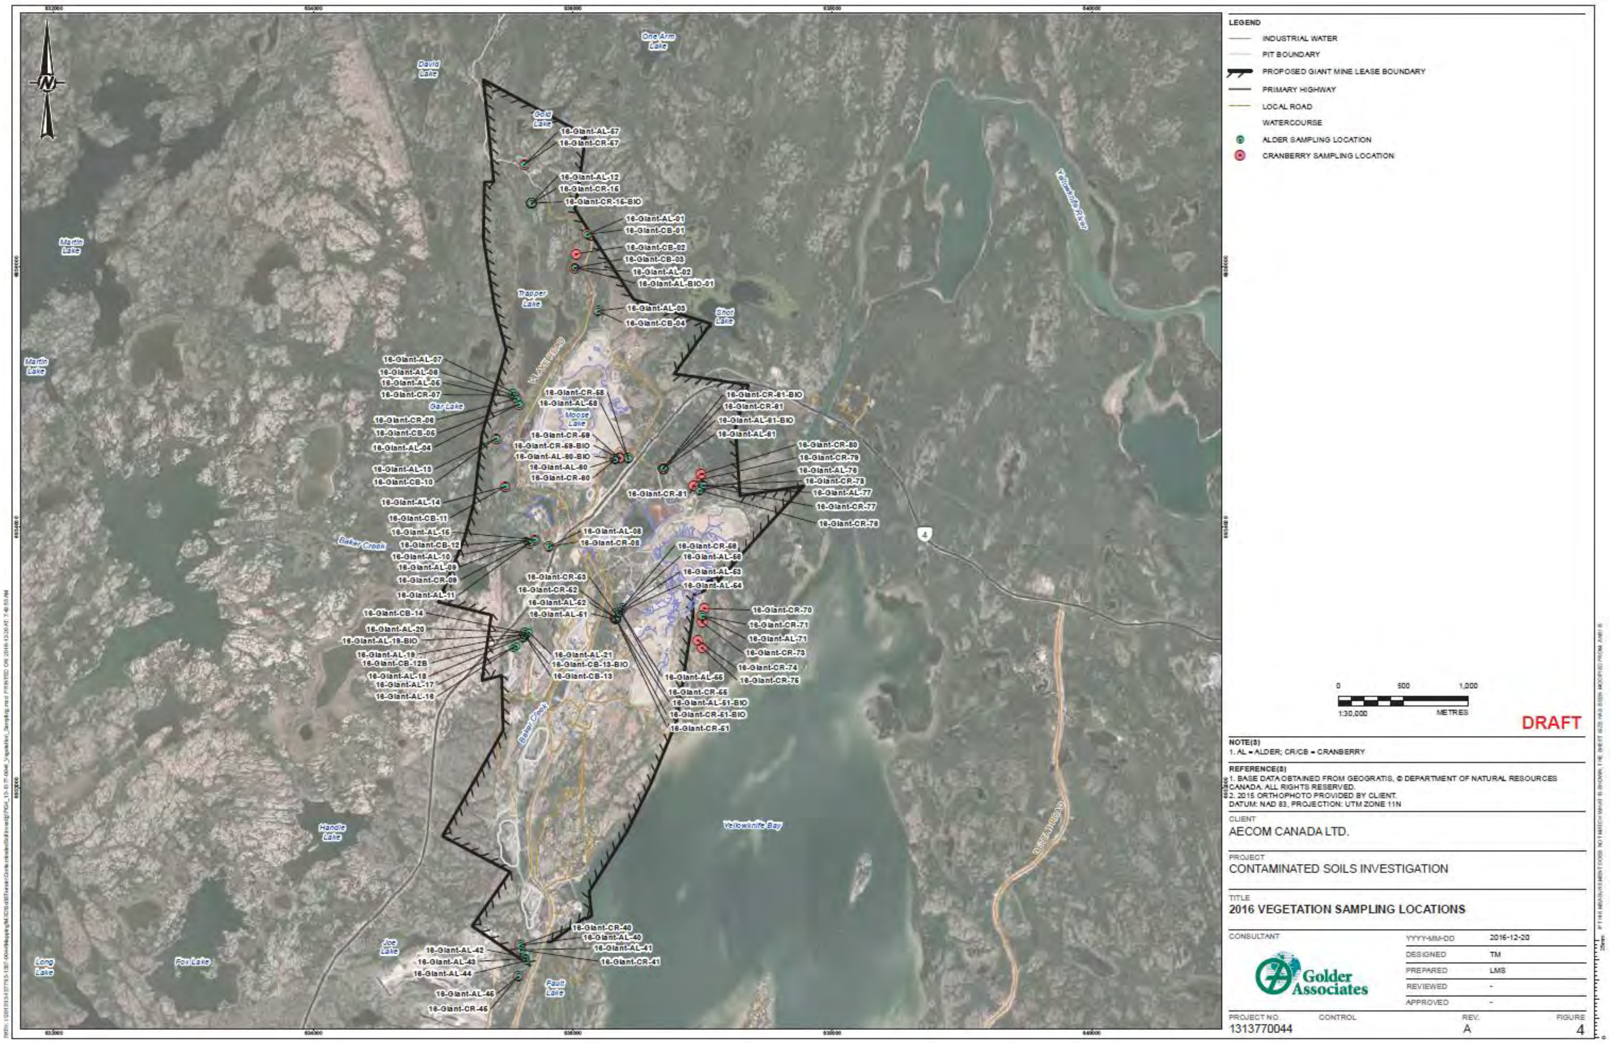
K.3.5.1 TFs from Soil

As described by Golder (2016a), in September 2016 soil and terrestrial vegetation sampling was conducted at the Giant Mine site. Leaves of cranberry (*Vaccinium vitis-idaea*) and alder (*Alnus* sp.) were collected to represent terrestrial forbs and shrubs. The locations of the samples are shown in Figure K.18. Only healthy plant samples were collected (i.e., no visible signs of disease or yellowing). In total, 51 vegetation samples were collected and sent for analysis. The soil sampling program targeted surficial samples (top 15cm).

Figure K.19 shows the relationship between soil and terrestrial plants (shown on a linear scale and log-scale) for antimony. Figure K.20 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a log-linear function ($\ln(Cp) = 0.938 * \ln(Cs) - 3.233$); the result as a dry weight concentration was converted to a wet weight concentration using a 57% moisture content based on the measured data.

The uptake by terrestrial vegetation will be represented by the site-specific log-linear equation in the assessment. This relationship was selected based on the visual examination of the data in Figure K.19 and the lower fractional bias.

Figure K.18 Locations of terrestrial plants and soil collected for site-specific transfer factors



Note: From by Golder (2016a); see Attachment 1 of Appendix B for complete memo.

Figure K.19 Measured terrestrial plant and soil data - antimony

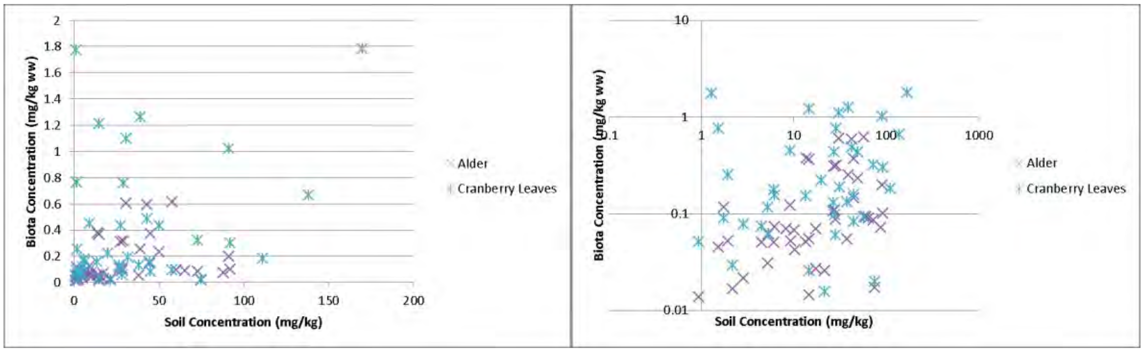


Figure K.20 Site-specific transfer factor for terrestrial plants and soil - antimony

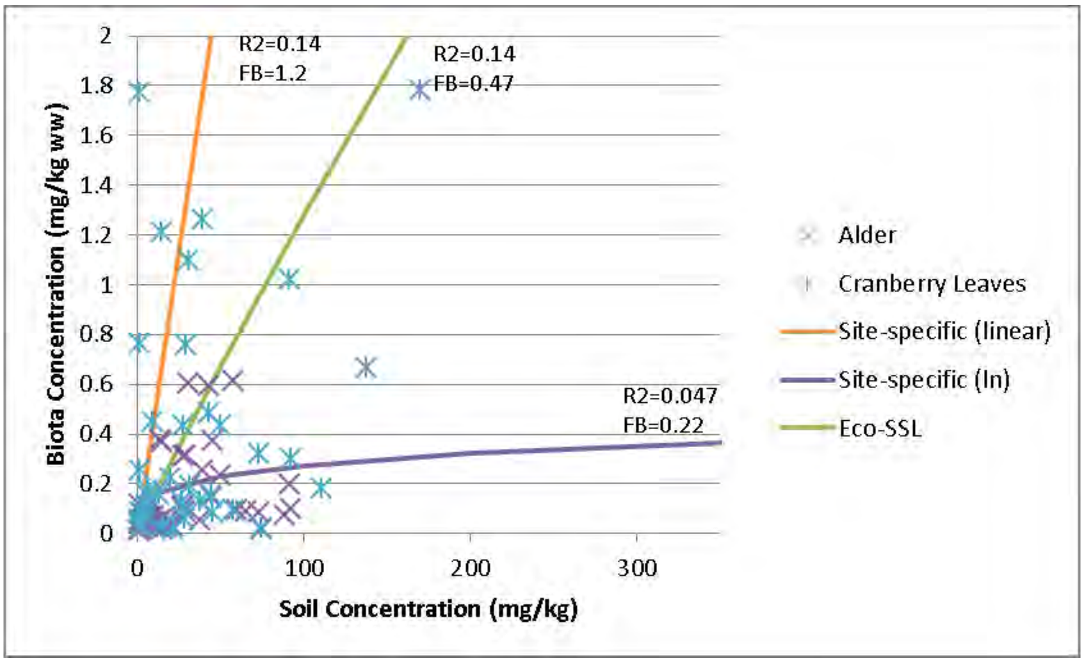

Figure K.21 shows the relationship between soil and terrestrial plants (shown on a linear scale and log-scale) for arsenic. Figure K.22 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a linear function (TF=0.03752); the result as a dry weight concentration was converted to a wet weight concentration using a 57% moisture content based on the measured data. The uptake by terrestrial vegetation will be represented by the site-specific log-linear equation in the assessment.

Figure K.21 Measured terrestrial plant and soil data - arsenic

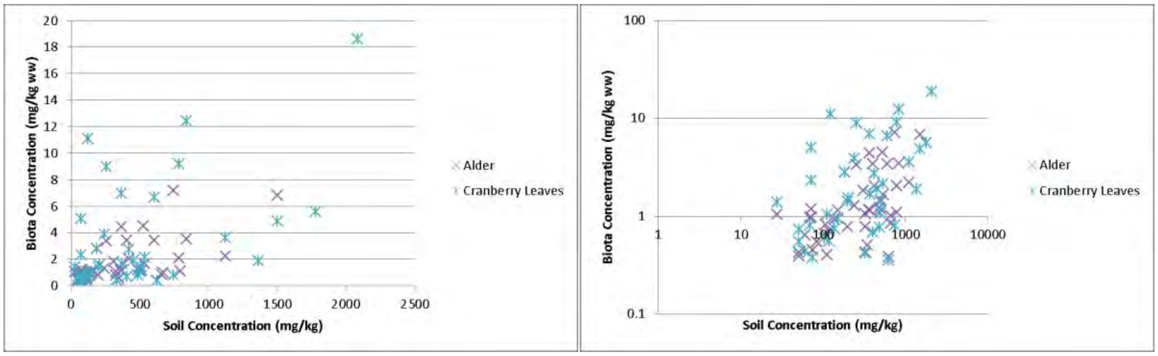

Figure K.22 Site-specific transfer factor for terrestrial plants and soil - arsenic

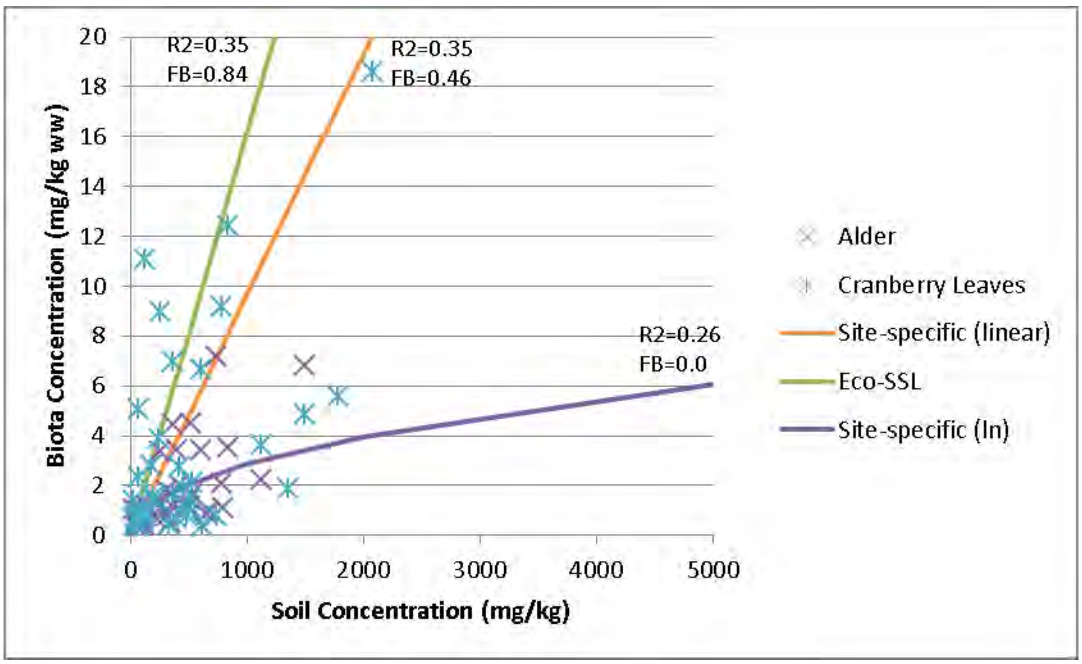

Figure K.23 shows the relationship between soil and terrestrial plants (shown on a linear scale and log-scale) for copper. Figure K.24 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a log-linear function ($\ln(Cp) = 0.394 * \ln(Cs) + 0.668$); the result as a dry weight concentration was converted to a wet weight concentration using a 57% moisture content based on the measured data. Based on the data shown in Figure K.23 there does not appear to be any relationship between copper levels in soil and terrestrial vegetation.

Figure K.23 Measured terrestrial plant and soil data - copper

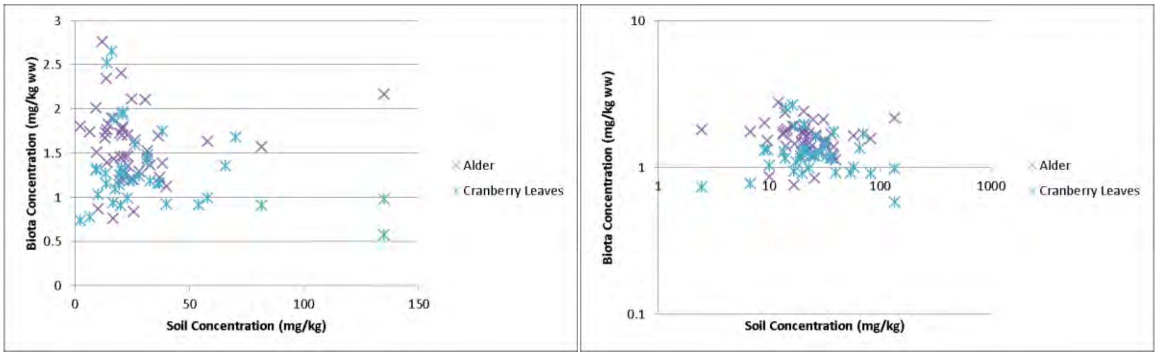

Figure K.24 Site-specific transfer factor for terrestrial plants and soil - copper

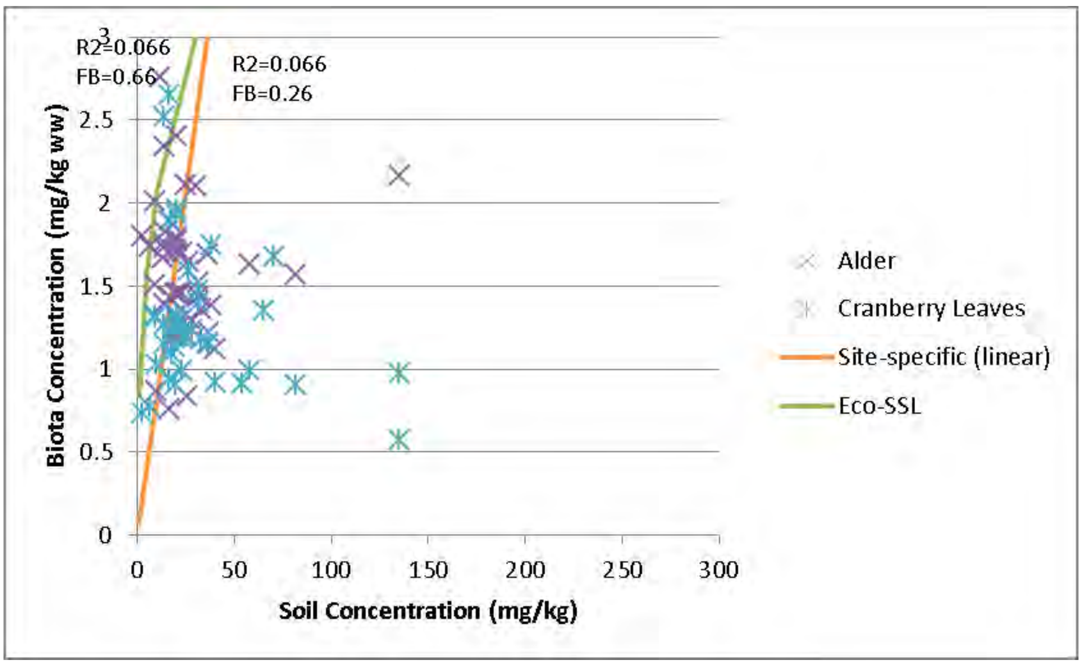

Figure K.25 shows the relationship between soil and terrestrial plants (shown on a linear scale and log-scale) for manganese. Figure K.26 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a linear function (TF=0.079); the result as a dry weight concentration was converted to a wet weight concentration using a 57% moisture content based on the measured data. The uptake by terrestrial vegetation will be represented by the site-specific linear equation in the assessment.

Figure K.25 Measured terrestrial plant and soil data - manganese

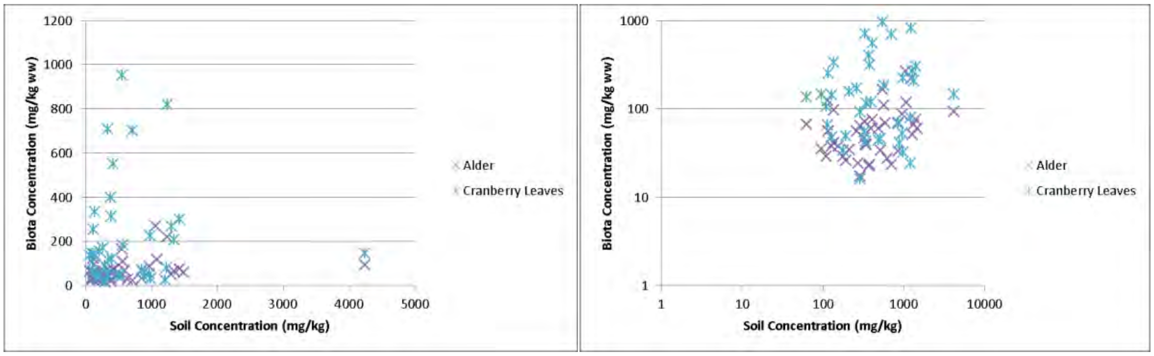

Figure K.26 Site-specific transfer factor for terrestrial plants and soil - manganese

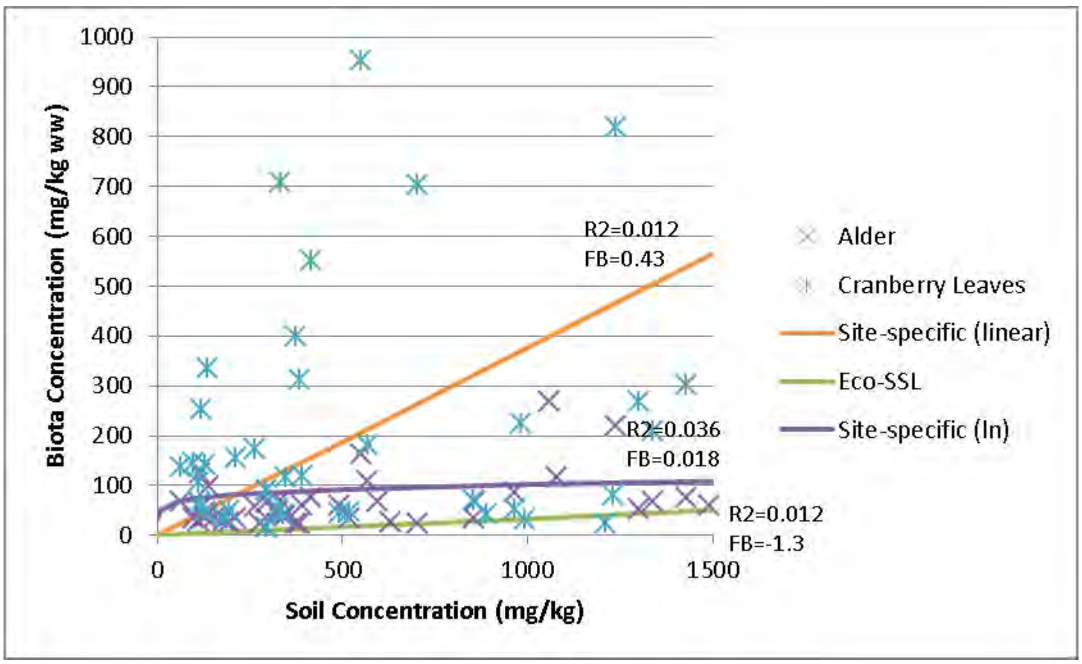

Figure K.27 shows the relationship between soil and terrestrial plants (shown on a linear scale and log-scale) for zinc. Figure K.28 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a log-linear function (ln(Cp) = 0.554 * ln(Cs) + 1.575); the result as a dry weight concentration was converted to a wet weight concentration using a 57% moisture content based on the measured data. The uptake by terrestrial vegetation will be represented by the site-specific log-linear equation in the assessment.

Figure K.27 Measured terrestrial plant and soil data - zinc

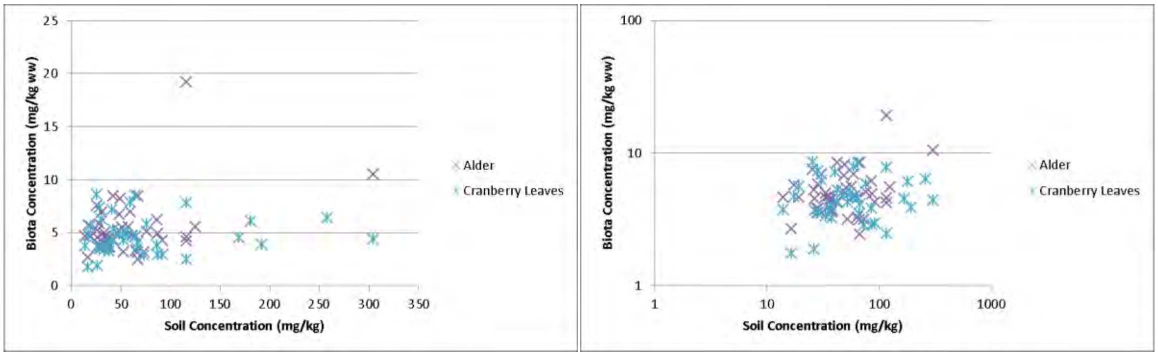

Figure K.28 Site-specific transfer factor for terrestrial plants and soil - zinc

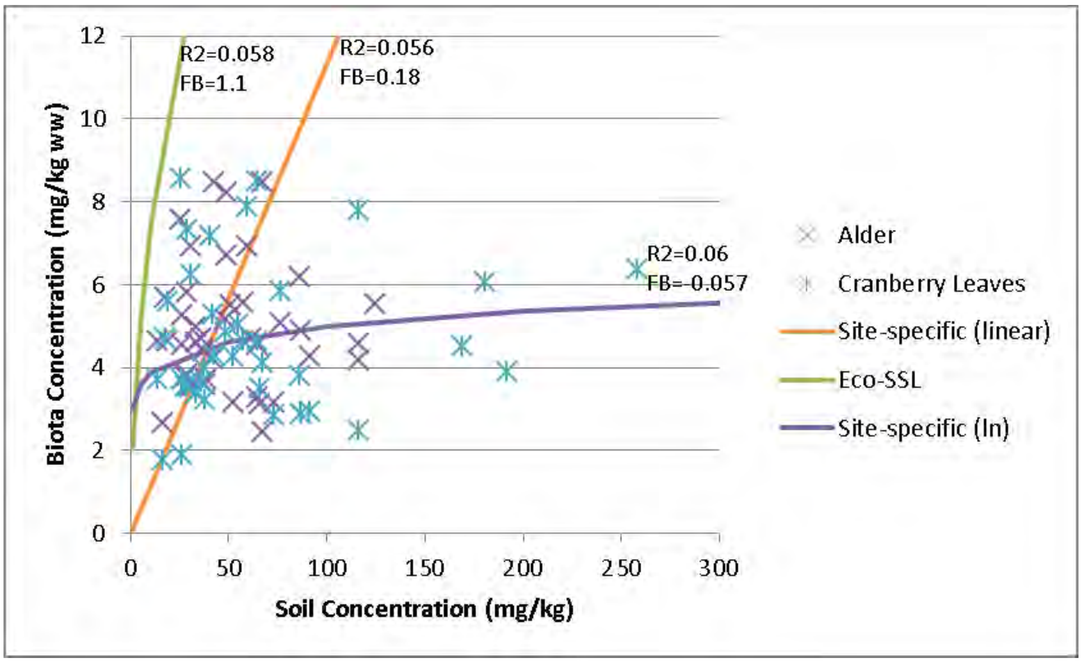


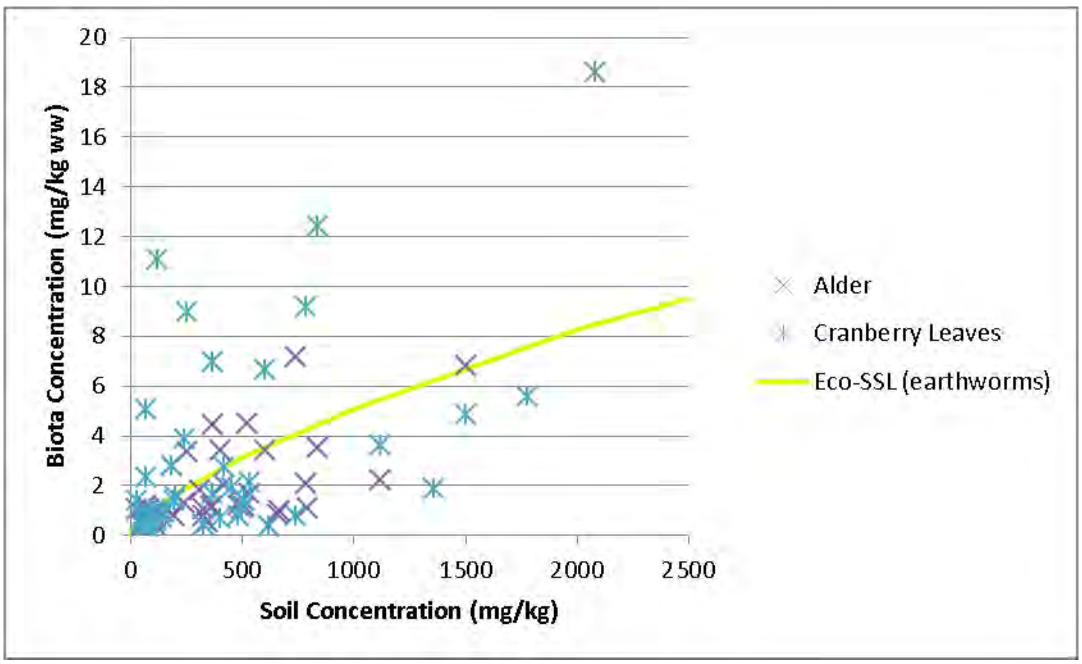
K.3.5.2 TF for Insects

Insects and invertebrates are an important component of the ecosystem; however, these are not well represented by traditional bioaccumulation factors. These factors are typically based on studies that examined earthworms. Due to the bedrock outcroppings and climatic conditions, earthworms are not present in this location. For this assessment, therefore, terrestrial insects (e.g., grasshoppers, bees, beetles, butterflies as well as spiders) were taken to be the same concentration as vegetation.

No specific literature information was found to validate this assumption for all the COPC. Hernout et al. (2013) did present information on some metals, which suggest that insects (on a dry weight basis) could be roughly equal to soil concentration (copper and zinc); however, the transfer of other metals (lead) was much lower. Differences in uptake and accumulation patterns in invertebrates are complex and can be further complicated for essential elements such as copper and zinc. For arsenic, Vermeulen et al. (2009) showed that insects such as beetles and woodlice have much lower concentrations than earthworms at the same location. Although information is available from this paper for insects such as beetles, the range of arsenic concentrations included is much less than at the Giant Mine, and as the relationship is non-linear, extrapolation is difficult.

A comparison is provided of the arsenic concentrations in vegetation and the earthworm bioaccumulation factor from literature (U.S. EPA 2007) is provided in Figure K.29. This figure shows that it is expected that the vegetation would be a reasonable basis for estimating insects. No information on insects was found for antimony.

Figure K.29 Comparison of terrestrial plants data to literature transfer factor - arsenic



K.3.5.3 Summary

The site-specific relationship between vegetation concentrations and COPC levels in soil are as shown below. Both current and future vegetation EPCs were based on these TFs.

Antimony: $C_{fol} = \exp(0.24*\ln(C_{soil})-2.4)$

Arsenic: $C_{fol} = \exp(0.47*\ln(C_{soil})-2.2)$

Copper: no relationship found, used current measured data
Manganese: $C_{fol} = C_{soil} * 0.38$
Zinc: $C_{fol} = \exp(0.11*\ln(C_{soil})-1.1)$

Where:
C_{fol} = Foliage COPC concentration (mg/kg (ww))
C_{soil} = Soil COPC concentration (mg/kg (dw))

The exposure assessment used derived TFs for foliage and then assumed concentrations for woody vegetation and fruits/flowers were the same as foliage, except in the rare cases where site-specific measurements were available. This was only the case for arsenic in wood vegetation and fruits/flowers in the East of Baker Creek quadrant. In these, the arsenic concentration in the future was calculated directly from the ratio of vegetation to soil, multiplied by the future soil concentration.

In the absence of any measured data, terrestrial insect concentrations were assumed to be the same as foliage.

K.3.6 Small Mammals (Shrew and Mouse)

Small mammals are exposed to soil by direct contact and ingestion and indirectly through food. Site-specific information was used to derive transfer factors.

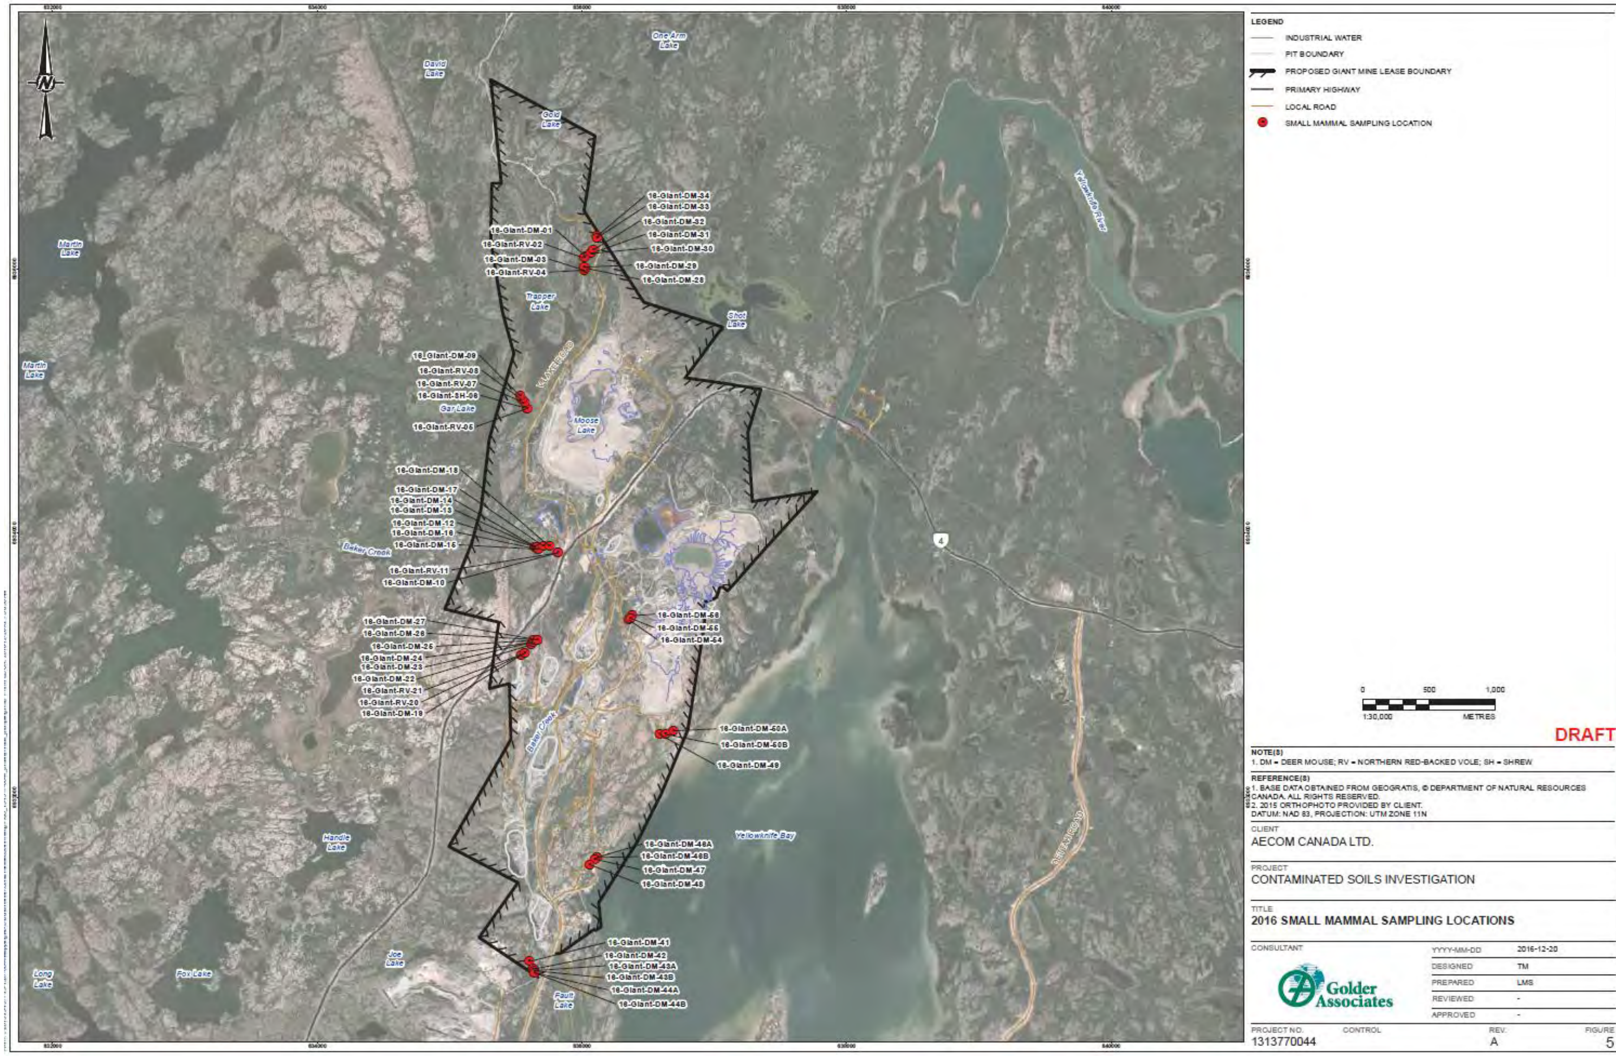
In the terrestrial environment, TFs are required for antimony, arsenic, copper, manganese, and zinc.

K.3.6.1 TFs from Soil

As described by Golder (2016a), in September 2016 small mammal sampling was conducted at the Giant Mine site. Mouse traps were set on 8 transects, where each transect consisted of 12 stations and where stations were made up of clusters of 2 or 3 traps. Each transect consisted of 25 traps and the traps were moved as mice were caught. The locations are shown on Figure K.30. Three small mammal species were caught, including deer mouse (*Peromyscus maniculatus*), northern red-backed vole (*Myodes rutilus*), and an unidentified shrew species (*Sorex* sp.). At stations where small mammals were caught, the field crew collected co-located soil and vegetation samples.

Figure K.31 shows the relationship between soil and small mammals (shown on a linear scale and log-scale) for antimony. One red-backed vole sample (16-Giant-RV-21) is outside the range of the other data; it also has high concentrations of other COPC. Golder did not note anything out of the ordinary about the red vole sample; it was one of the largest mammal sample collected (22.25 g) (Golder 2017a). Figure K.32 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. No literature values were found. The uptake by small mammals will be represented by the site-specific log-linear equation in the assessment.

Figure K.30 Locations of small mammal and soil collected for site-specific transfer factors



Note: From Golder (2016a); see Attachment 1 of Appendix B for complete memo.

Figure K.31 Measured small mammal and soil data - antimony

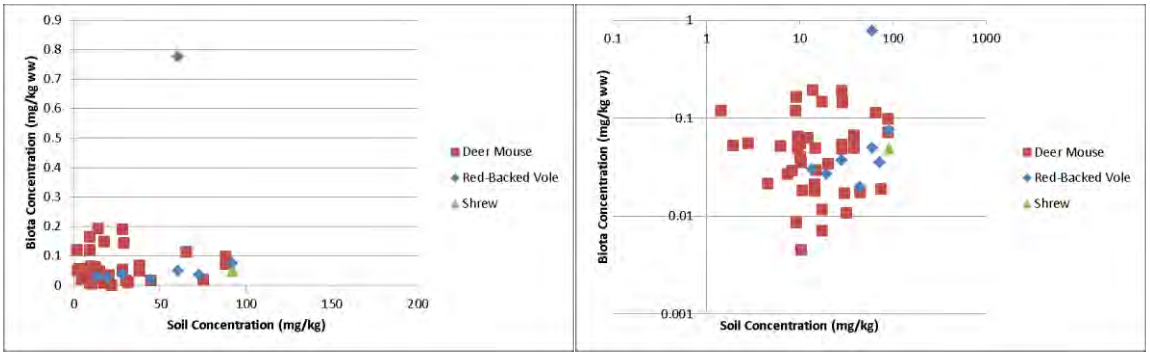


Figure K.32 Site-specific transfer factor for small mammals and soil - antimony

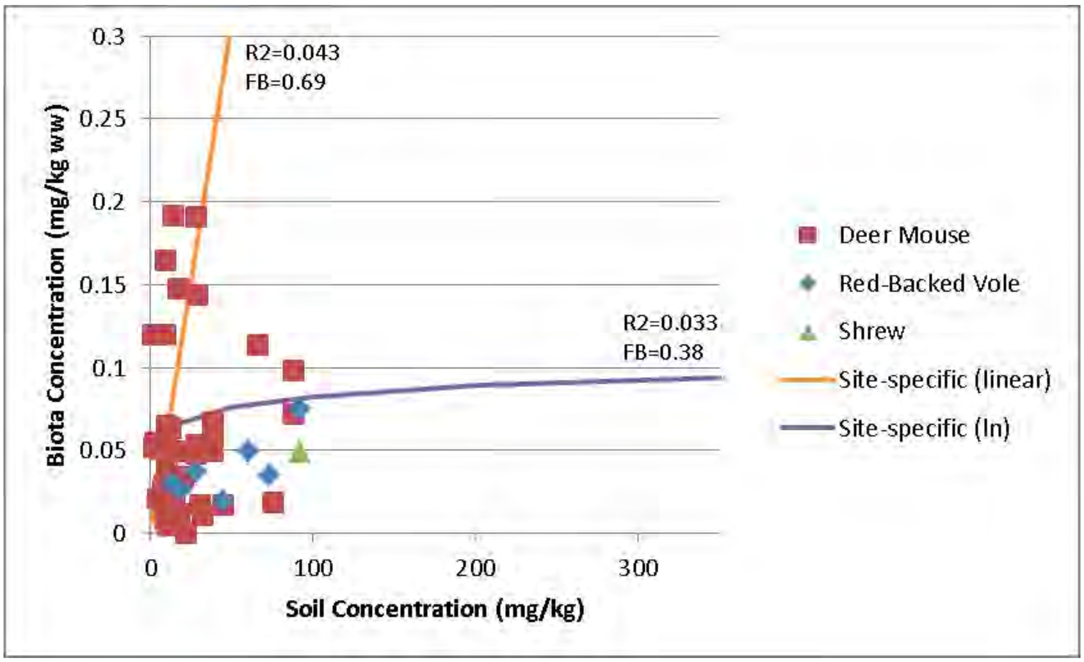

Figure K.33 shows the relationship between soil and small mammals (shown on a linear scale and log-scale) for arsenic. Figure K.34 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a log-linear function (ln(Cm) = 0.8188 * ln(Cs) – 4.8471); the result as a dry weight concentration was converted to a wet weight concentration using a 71% moisture content based on the measured data. The uptake by small mammals will be represented by the site-specific log-linear equation in the assessment.

Figure K.33 Measured small mammal and soil data - arsenic

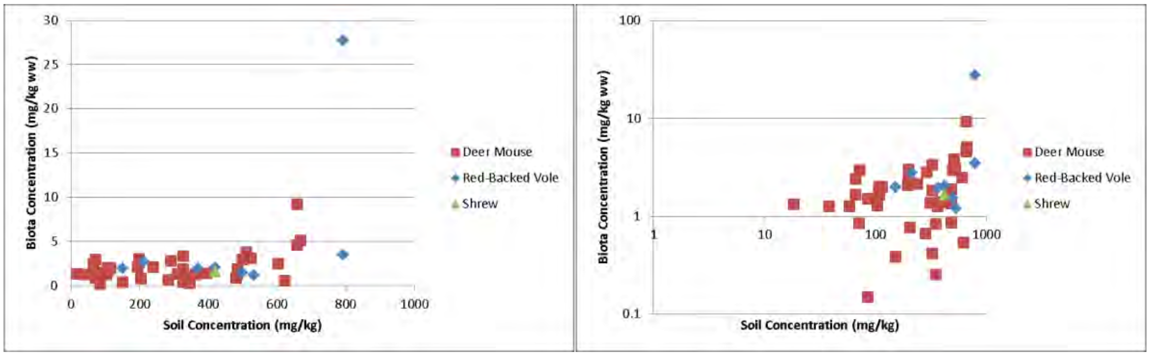

Figure K.34 Site-specific transfer factor for small mammals and soil - arsenic

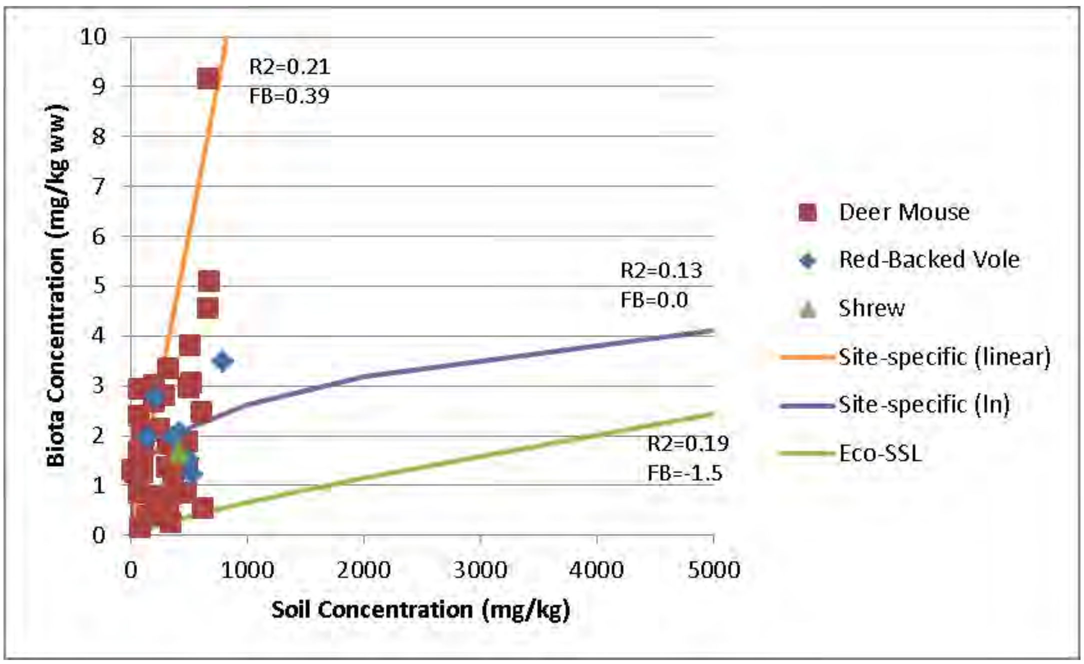

Figure K.35 shows the relationship between soil and small mammals (shown on a linear scale and log-scale) for copper. Figure K.36 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a log-linear function ($\ln(Cm) = 0.1444 * \ln(Cs) + 2.042$); the result as a dry weight concentration was converted to a wet weight concentration using a 71% moisture content based on the measured data. The uptake by small mammals will be represented by the site-specific log-linear equation in the assessment.

Figure K.35 Measured small mammal and soil data - copper

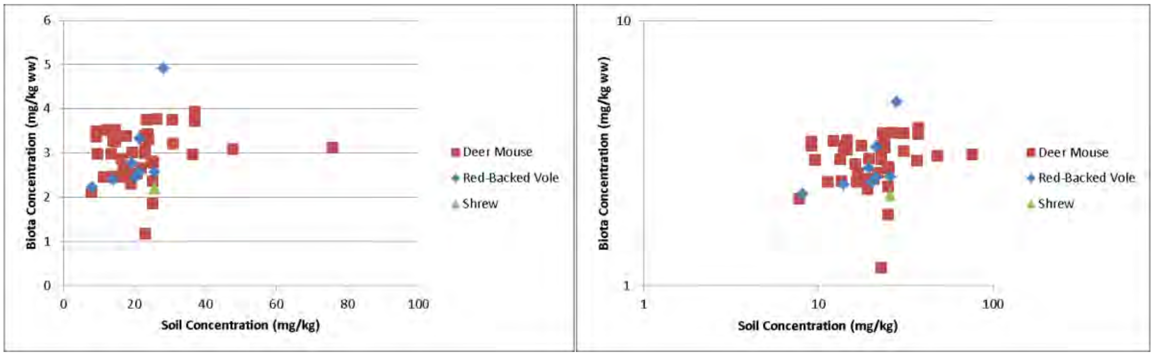

Figure K.36 Site-Specific transfer factor for small mammals and soil - copper

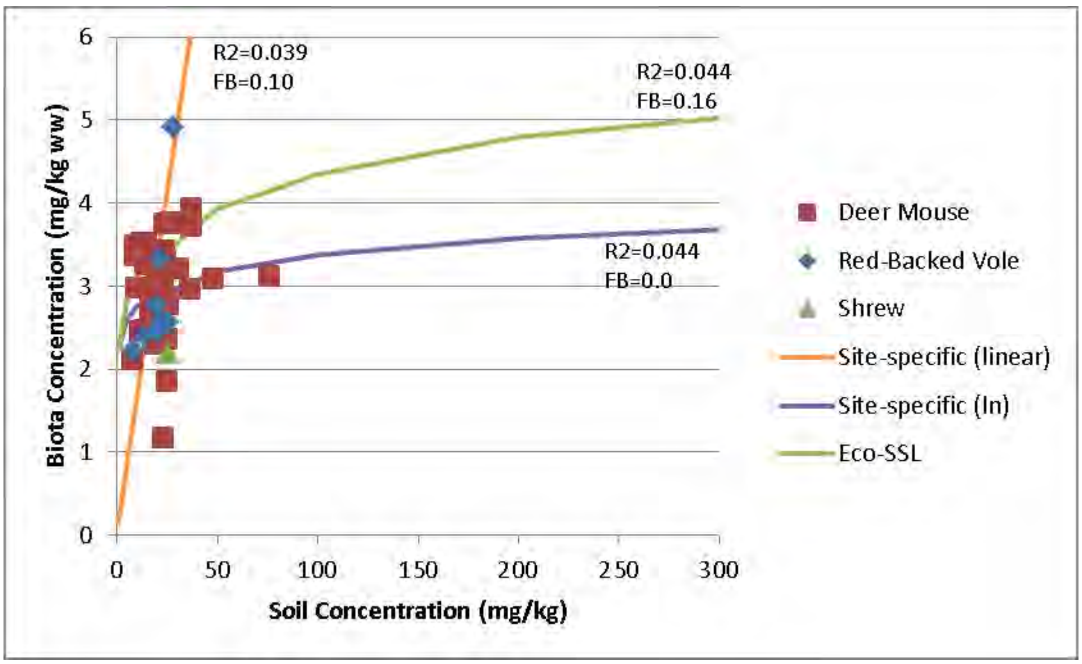

Figure K.37 shows the relationship between soil and small mammals (shown on a linear scale and log-scale) for manganese. Figure K.38 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a linear function (Cm = 0.0205 * Cs); the result as a dry weight concentration was converted to a wet weight concentration using a 71% moisture content based on the measured data. The uptake by small mammals will be represented by the site-specific linear equation in the assessment.

Figure K.37 Measured small mammal and soil data - manganese

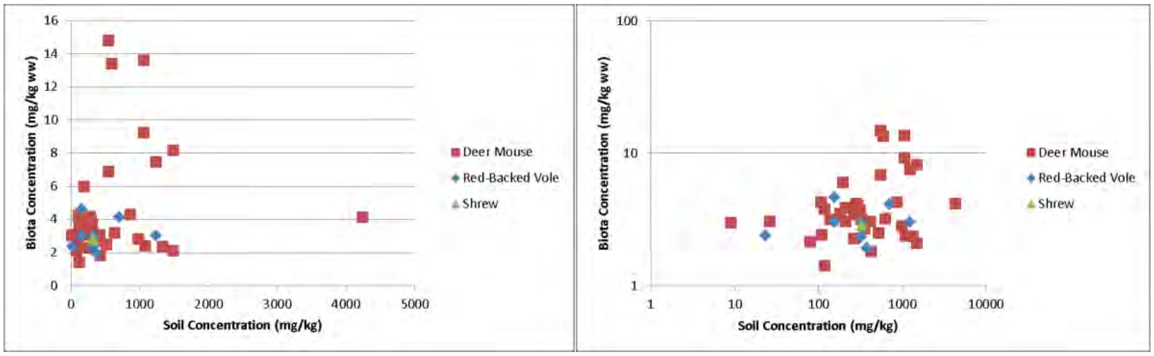

Figure K.38 Site-specific transfer factor for small mammals and soil - manganese

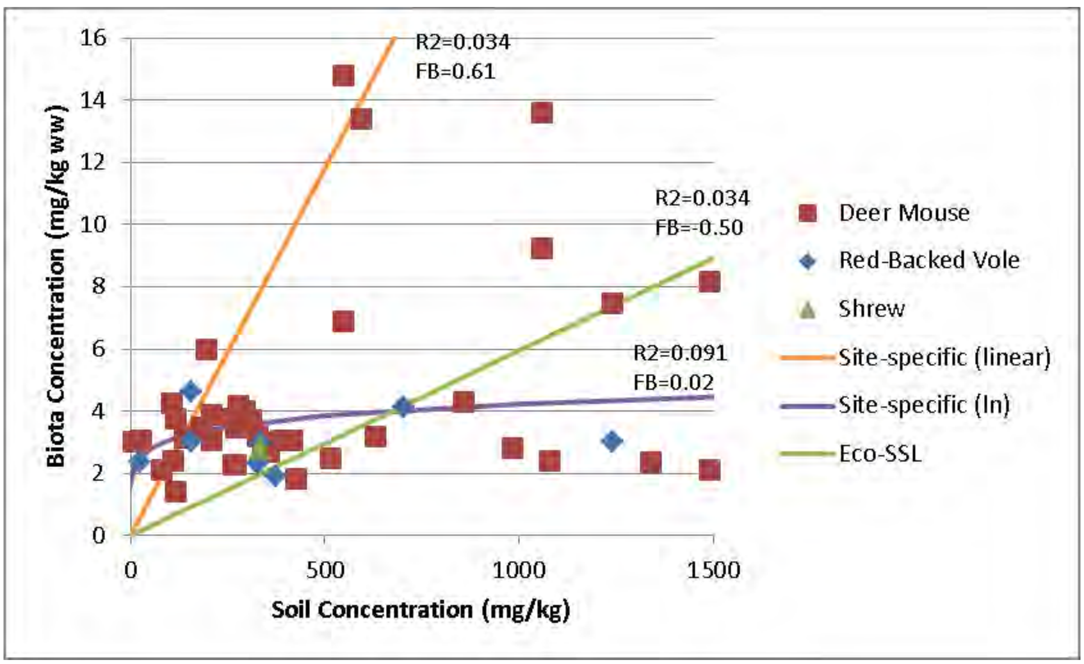

Figure K.39 shows the relationship between soil and small mammals (shown on a linear scale and log-scale) for zinc. Figure K.40 shows the site-specific transfer factor for all data combined over an appropriate range of concentrations for the assessment. For comparison purposes, a function from literature is also shown. The literature value is from Eco-SSL (U.S. EPA 2007) as is expressed as a log-linear function ($\ln(Cm) = 0.0706 * \ln(Cs) + 4.3632$); the result as a dry weight concentration was converted to a wet weight concentration using a 71% moisture content based on the measured data. As can be seen from the data (Figure K.39), there is no clear relationship between soil concentration and small mammals for zinc, since the Eco-SSL information provided a reasonable approximation of the concentrations at the site this relationship was used.

Figure K.39 Measured small mammal and soil data - zinc

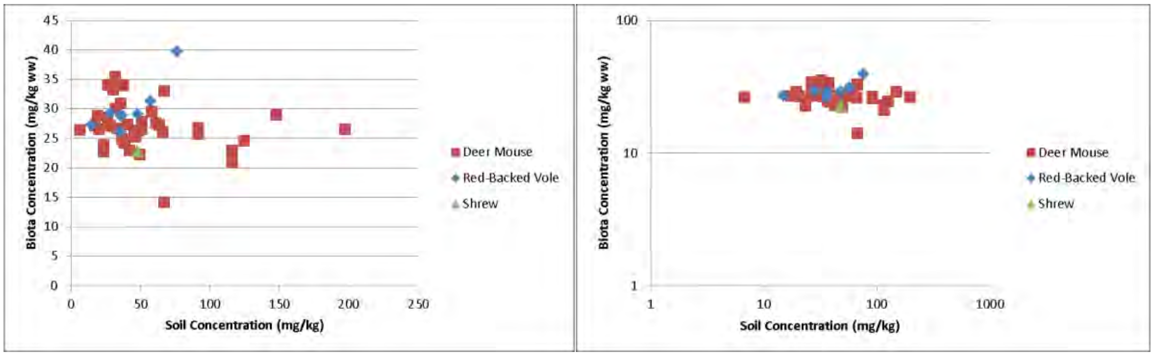

Figure K.40 Site-specific transfer factor for small mammals and soil - zinc

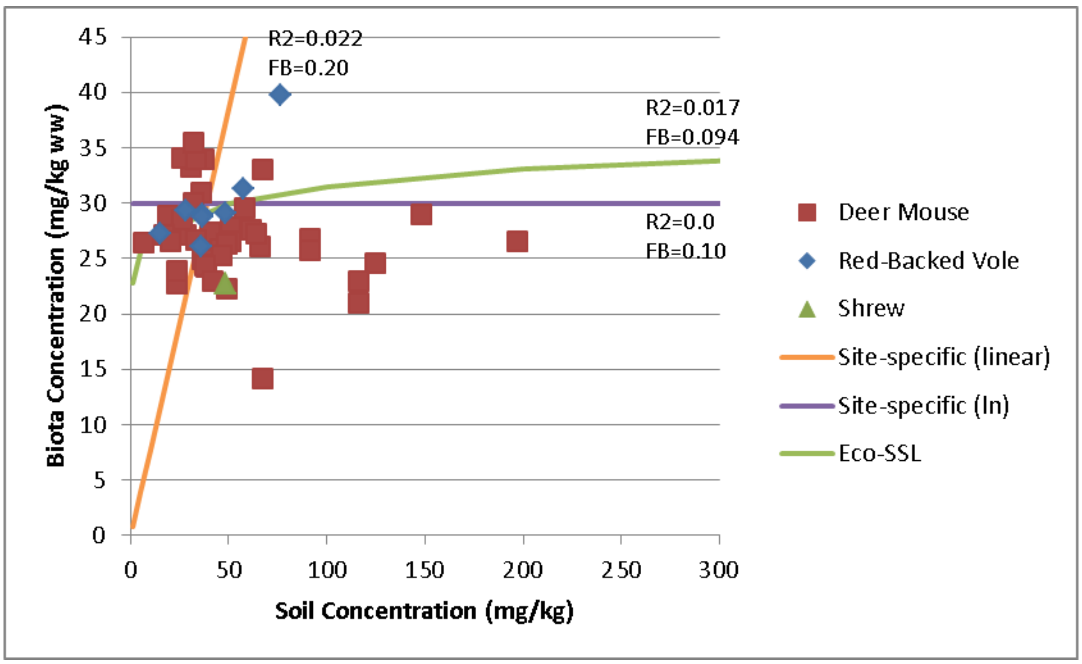

K.3.6.2 Summary

The site-specific relationship between small mammals and COPC levels in soil are as shown below. Both current and future vegetation EPCs were based on these TFs.

Antimony: $C_{sm} = \exp(0.11*\ln(C_{soil})-3)$

Arsenic: $C_{m} = \exp(0.28*\ln(C_{soil})-0.97)$

Copper: $C_{sm} = \exp(0.088*\ln(C_{soil})-0.81)$

Manganese: $C_{sm} = C_{soil} * 0.0205 * (1-0.71)$

Zinc: $C_{sm} = \exp(0.0706*\ln(C_{soil})+4.3632) * (1-0.71)$

Where:

C_{sm} = Small mammal (shrew and mouse) COPC concentration (mg/kg (ww))

C_{soil} = Soil COPC concentration (mg/kg (dw))

K.4 Current EPCs

The EPCs selected to represent current conditions are presented in Table K.9 and Table K.10 for use with the aquatic and terrestrial receptors, respectively. Some EPCs are based directly on measured data, while others are calculated using site-specific transfer factors (discussed in Section K.3) that were developed using measured data.

Available site data and details on the data handling are provided in Appendix B. The datasets used to derive EPCs directly are discussed further in Section K.4.1 and Section K.4.2.

For the purposes of determining EPCs, the U.S. EPA (2002) recommends the 95% UCLM as a reasonable estimate of the concentration that receptors will likely be exposed to over time. For the ERA, a 95th percentile was used as the EPC in instances where there were insufficient data available. The approach for developing the EPCs at the various ERA receptor locations are as follows:

- If a sufficient number of samples are available (i.e., 10 or more samples) the 95% UCLM was selected as the EPC which is considered to be a reasonable estimate of what the receptor will be exposed to over time.
- If there are insufficient numbers of samples (i.e., less than 10), the 95th percentile was selected as the EPC.

The 95% UCLM was calculated using ProUCL, which is a statistical program that provides 95% UCLM recommendations (based on data distribution, data set size, skewness, and percentage of non-detect observations) on how to obtain an accurate 95% UCLM. ProUCL may suggest more than one 95% UCLM estimate; in these cases, the highest appropriate 95% UCLM was selected. It is noted that the CCME (2016) suggests that the BCA bootstrap approach from ProUCL can be used for the majority of datasets; the selection of the highest 95% UCLM that may be greater than the BCA bootstrap recommendation is, therefore, a conservative approach.

Table K.9 Current EPCs for aquatic receptors

Media	Location	Units	Antimony	Arsenic	Chloride	Sulphate	Comment
Surface Water	Back Bay	mg/L	$3.5x10^{-4}$	$2.6x10^{-3}$	3.4	10.7	95% UCLM of available data.

K.4.1 Aquatic Environment

As shown in Table K.9, with the exception of EPCs for surface water and sediment, all other EPCs for aquatic media were developed using the site-specific transfer factors discussed in Section K.3. The following sections present the available measured data that went into developing the current surface water and sediment EPCs for the ERA.

K.4.1.1 Lower Baker Creek (Reach 0 to 6)

Lower Baker Creek surface water sample locations are shown in Figure K.41 and summary statistics for each of the Baker Creek areas considered in the ERA are shown in Table K.11. Surface water EPCs were developed for both aquatic and terrestrial COPC as surface water is an evaluated pathway for both aquatic and terrestrial receptors. As can be seen, there is very good coverage of lower Baker Creek and this dataset is considered to be adequate for use in the ERA.

Note: N – number of samples; MDL – method detection limit; Min - minimum; Max – maximum; StDev – standard deviation; GeoMean – geometric mean; 95th % – 95th percentile; 95% UCLM – 95th percentile upper confidence limit of the mean (only calculated if N ≥ 10); NA – statistic not generated due to lack of data.

Sediment sample locations are shown in Figure K.42, and summary statistics for each of the Baker Creek areas considered in the ERA are shown in Table K.12. Sediment EPCs were only generated for aquatic COPC, as sediment ingestion is not a pathway considered for terrestrial receptors. Chloride and sulphate are conservative parameters and are assumed to not undergo transfer to sediment and are, therefore, not included in the table. Sediment EPCs were generated to support the assessment of benthic invertebrates as well as for the food chain model. For the ERA, the surficial sediment samples were included in the assessment, specifically the samples collected from the 0-10 cm horizon (note: if samples were collected from both 0-5 cm and 5-10 cm, only the upper layer was used). As can be seen, with at least eight samples from each evaluated segment, there is good coverage of lower Baker Creek, and this dataset is considered to be adequate for use in the ERA.

K.4.1.2 Back Bay and North Yellowknife Bay

Back Bay surface water sample locations are shown in Figure K.43 and summary statistics for Back Bay are shown in Table K.13. With 48 samples, there is very good coverage of Back Bay and this dataset is considered to be adequate for use in the ERA.

North Yellowknife Bay was included as a compartment in the water quality and sediment quality modelling. The summary statistics for North Yellowknife Bay are provided in Table K.14 and Figure K.44 shows the sample locations. The dataset provides a reasonable basis for characterizing the conditions in the area for modelling purposes.

Back Bay sediment sample locations are shown in Figure K.43, and summary statistics for the available data are shown in Table K.15. As can be seen, with 27 samples, there is reasonable coverage of Back Bay, and this dataset is considered to be adequate for use in the ERA.

North Yellowknife Bay was included as a compartment in the water quality and sediment quality modelling. The summary statistics for North Yellowknife Bay are provided in Table K.16, and Figure K.44 shows the sample locations. The dataset provides a reasonable basis for characterizing the conditions in the area for modelling purposes.

For the assessment of benthic invertebrates, a larger area was considered, and Table K.17 provides the summary statistics for North Yellowknife Bay and Back Bay combined. As discussed previously, for the ERA, only surficial sediment samples (0-10 cm) were included in the assessment.

K.4.1.3 Trapper Lake

Surface water EPCs were developed for Trapper Lake for use as a drinking water source for terrestrial receptors on the Trapper Lake North quadrant of the Giant Mine. This pairing was made as Trapper Lake is the closest waterbody to the Trapper Lake North quadrant of the Giant Mine. Summary statistics for Trapper Lake surface water data are shown in Table K.18 and sample locations are shown in Figure K.45.

Figure K.45 Surface water sampling locations in Trapper Lake

K.4.1.4 Background and Baseline Locations

The upper reaches of Baker Creek (Reach 7-11) were used in the ERA to be representative of baseline conditions in Baker Creek. Upper Baker Creek surface water summary statistics are shown in Table K.19, and additional discussion is provided in Appendix C. As can be seen, with 48 samples, there is very good coverage of upper Baker Creek, and this dataset is considered to be adequate for representing baseline Baker Creek conditions in the ERA.

While the upper reaches of Baker Creek are appropriate to represent baseline conditions in Baker Creek, background water quality in the area was also used for Back Bay. Summary statistics on this dataset is provided in Table K.20, and additional information is provided in Appendix C.

Table K.19 Surface water summary statistics for upper Baker Creek (Reach 7-11)

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95th %	95% UCLM
Antimony	mg/L	28	1	$7.0x10^{-4}$	0.30	0.01	0.06	$1.5x10^{-3}$	$5.0x10^{-3}$	$2.5x10^{-3}$

Sulphate	mg/L	20	0	2.7	21	8.9	7.8	6.1	20	16
Zinc	mg/L	19	17	0.0015	0.011	0.0026	0.0022	0.0022	0.0061	0.0046

Note: N – number of samples; MDL – method detection limit; Min – minimum; Max – maximum; StDev – standard deviation; GeoMean - geometric mean; 95^{th} % – 95^{th} percentile; 95% UCLM – 95^{th} percentile upper confidence limit of the mean (only calculated if N ≥ 10); NA – statistic not generated.

Similar to for surface water, measured sediment levels in the upper reaches of Baker Creek were taken to be representative of baseline conditions in Baker Creek. Summary statistics on this dataset are shown in Table K.21, and additional information is provided in Appendix C.

Background sediment levels applicable to the Back Bay area were derived based on measured levels from South Yellowknife Bay (near Horseshoe Island); summary statistics for this dataset are provided in Table K.22, and additional information is provided in Appendix C. Due to the limited number of samples (N=5), the average was used as the appropriate statistic for comparison to the data from Back Bay and North Yellowknife Bay.

A third background/baseline sediment EPC was developed for use with ecological receptors that can be present in both river and lake systems and may range across these environments. For these EPCs, sediment data from South Yellowknife Bay (near Horseshoe Island) was combined with measurements from Yellowknife River; summary statistics for this dataset are shown in Table K.23 and discussed further in Appendix C.

Table K.21 Sediment summary statistics for upper Baker Creek (Reach 7-11)

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95th %	95% UCLM

K.4.2 Terrestrial Environment

As shown in Table K.10, with the exception of EPCs for soil, some terrestrial vegetation, and some wildlife, all other EPCs for terrestrial media were developed using the site-specific transfer factors discussed in Section K.3. The following sections present the available measured data that went into developing the EPCs for the ERA.

K.4.2.1 Giant Site

In developing EPCs for the Giant Mine, it was conservatively assumed that the entire site consists of accessible soil covered land. While it is known that there are portions of the site that are bare bedrock with soil in crevices, without further information, this could not be accounted for in the assessment. Only surficial soil samples (0-10 cm) were considered in generating the summary statistics.

Trapper Lake North

Trapper Lake North soil sample locations are shown in Figure K.46 and summary statistics for the dataset are shown in Table K.24. As can be seen with over 58 samples from this quadrant, the dataset is considered to be adequate for use in the ERA.

Table K.24 Soil summary statistics for Trapper Lake North

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95th %	95% UCLM
Antimony	mg/kg dw	61	0	0.94	165	29	31	18	92	36

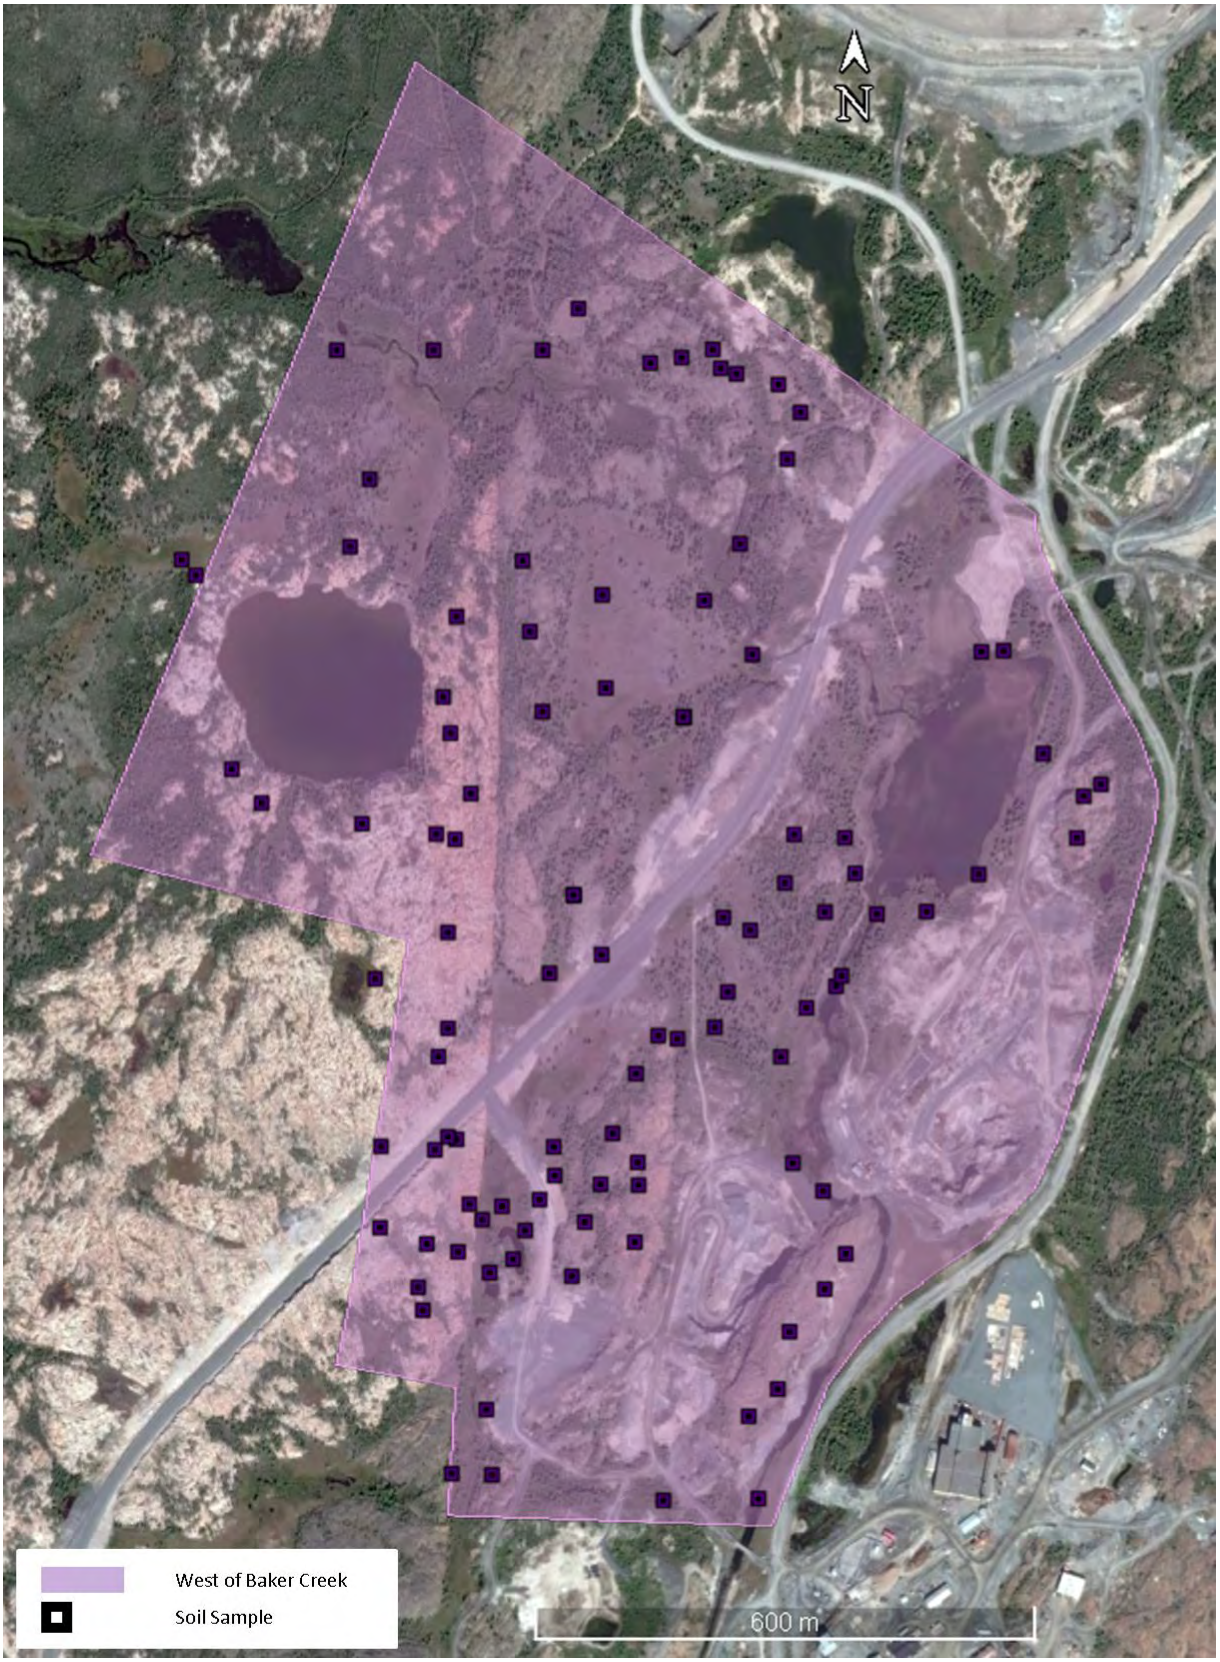
Note: N – number of samples; MDL – method detection limit; Min - minimum; Max – maximum; StDev – standard deviation; GeoMean – geometric mean; 95^{th} % – 95^{th} percentile; 95% UCLM – 95^{th} percentile upper confidence limit of the mean (only calculated if N ≥ 10); NA – statistic not generated.

Figure K.47 Soil sampling locations in West of Baker Creek



East of Baker Creek

East of Baker Creek soil sample locations are shown in Figure K.48, and summary statistics for the dataset are shown in Table K.26. As can be seen with over 128 samples from this quadrant, the dataset is considered to be adequate for use in the ERA. In addition to soil, measured arsenic levels in fruits/flowers and woody vegetation were used directly in developing EPCs; locations of these samples are shown in Figure K.49, and summary statistics for these media are shown in Table K.27.

Table K.26 Soil summary statistics for East of Baker Creek

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95^{th} %	95% UCLM

Figure K.50 Soil sampling locations in South Baker Creek

Giant Mine Site-Wide

To develop EPCs for the entire Giant Mine, the datasets for the four quadrants were combined; these EPCs were developed to estimate exposure for ecological receptors with larger home ranges such as the fox, falcon, owl, and lynx. Summary statistics for the combined dataset are shown in Table K.29. As can be seen with over 430 samples from this quadrant, the dataset is considered to be adequate for use in the ERA.

Table K.29 Soil summary statistics for Giant Mine site-wide

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95^{th} %	95% UCLM
Antimony	mg/kg dw	452	10	0.79	$1.1x10^4$	137	569	42	410	162
Arsenic	mg/kg dw	505	0	18	$8.7x10^4$	1,865	4,642	711	5,928	2,766

Manganese	mg/kg dw	451	0	7.0	9,500	798	1,178	402	2,930	969
Zinc	mg/kg dw	430	3	6.7	1,774	126	155	83	337	134

Note: N – number of samples; MDL – method detection limit; Min – minimum; Max – maximum; StDev – standard deviation; GeoMean – geometric mean; 95^{th} % – 95^{th} percentile; 95% UCLM – 95^{th} percentile upper confidence limit of the mean (only calculated if N ≥ 10); NA – statistic not generated.

K.4.2.2 Giant Townsite

While no terrestrial receptors were evaluated on the Giant Townsite area, some aquatic receptors (e.g., mink) that were evaluated in Back Bay ingest terrestrial media and so were linked to conditions in the Giant Townsite area for these intakes. Summary statistics for the data collected from the Giant Townsite area are provided in Table K.30. Available soil data for the Giant Townsite are discussed in Appendix B.

Table K.30 Soil summary statistics for the Giant Townsite

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95^{th} %	95% UCLM
Antimony	mg/kg dw	31	4	3.3	198	45	49	26	146	76

Zinc	mg/kg dw	31	0	17	571	157	129	111	385	196

Note: N – number of samples; MDL – method detection limit; Min - minimum; Max – maximum; StDev – standard deviation; GeoMean – geometric mean; 95^{th} % – 95^{th} percentile; 95% UCLM – 95^{th} percentile upper confidence limit of the mean (only calculated if N ≥ 10); NA – statistic not generated.

K.4.2.3 Background

The soil dataset used to develop background EPCs for the ERA is the background soil dataset developed for the Yellowknife Greenstone Belt, which is presented and discussed fully in Appendix C. Summary statistics for this dataset are provided in Table K.31.

Table K.31 Soil summary statistics for Greenstone Belt background areas

COPC	Unit	N	N<MDL	Min	Max	Mean	StDev	GeoMean	95^{th} %	95% UCLM
Antimony	mg/kg dw	28	1	0.05	11	1.9	2.2	1.1	4.2	2.9

K.4.2.4 Moose and Caribou EPCs

The EPCs for moose and caribou were based off of measured data collected as part of the voluntary sampling program, which is presented in Appendix B. Caribou EPCs were set equal to a single reindeer meat sample that was collected from Inuvik and submitted to the program. As caribou are expected to only rarely come close to the Giant Mine, the use of a remote sample well outside the influence of the site is appropriate. This sample was taken to be representative of both exposure and reference caribou.

Moose EPCs for background were set to an average of two moose flesh samples collected from over 50 km from the site; these moose locations are labeled samples 009 and 020 in Figure K.51. The two moose flesh samples collected from closest to the Giant Mine (both shot within 25 km of the site) were averaged and used as EPCs for the moose exposed to the Giant Mine. The moose used in calculating exposure EPCs are labeled as samples 032 and 098 in Figure K.51.

Figure K.51 Moose flesh sample locations

K.5 Water and Sediment Model

Water quality models are tools that can be used to determine changes in water and sediment quality due to changes in contaminant loads, taking into account natural process in the environment. Modelling can be used to assist in assessments and decision making. There are different levels of water quality models from simple basic model to those with increasing various levels of complexity. For this application, a simple, empirically-based approach was adopted to predict future concentrations. The model provides a high-level approximation of the change in concentration with the implementation of remediation activities. The final design of the the Giant Mine Remediation Program (GMRP) will be supported by more refined modelling.

Future modelling of water and sediment concentrations in Baker Creek and Yellowknife Bay was completed to estimate post-remediation conditions for arsenic (As), antimony (Sb), chloride (Cl), and sulphate (SO_4), as discussed in Section 4 and Appendix D. The model used spreadsheet (Microsoft Excel) calculations and input assumptions based on measured data to estimate future concentrations at specific points in time: Current (year 2016); End of Remediation (year 2030); Post Remediation (years 2040, 2060, 2080, and 2120). Baker Creek segments, shown in Figure K.52, were considered consistent with Golder (2016b) calculations: Reach 7 to 11; Reach 6, Reach 4 and 5; Reach 1 to 3; and Reach 0. Yellowknife Bay was segmented consistent with SENES (2006), as shown in Figure K.53.

Figure K.52 Baker Creek segments considered for calculations

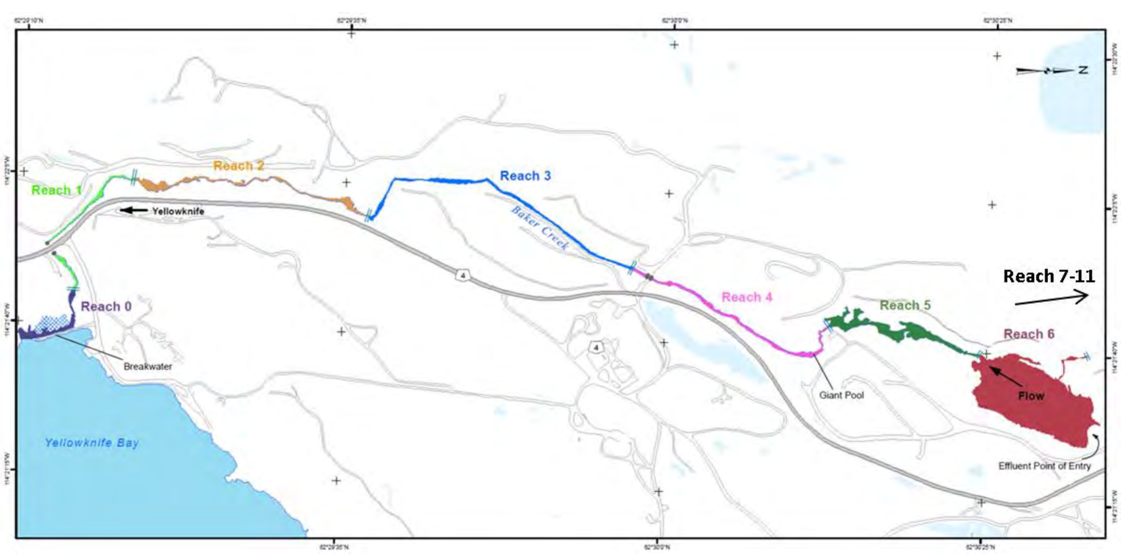

Figure K.53 Yellowknife Bay segments considered for calculations

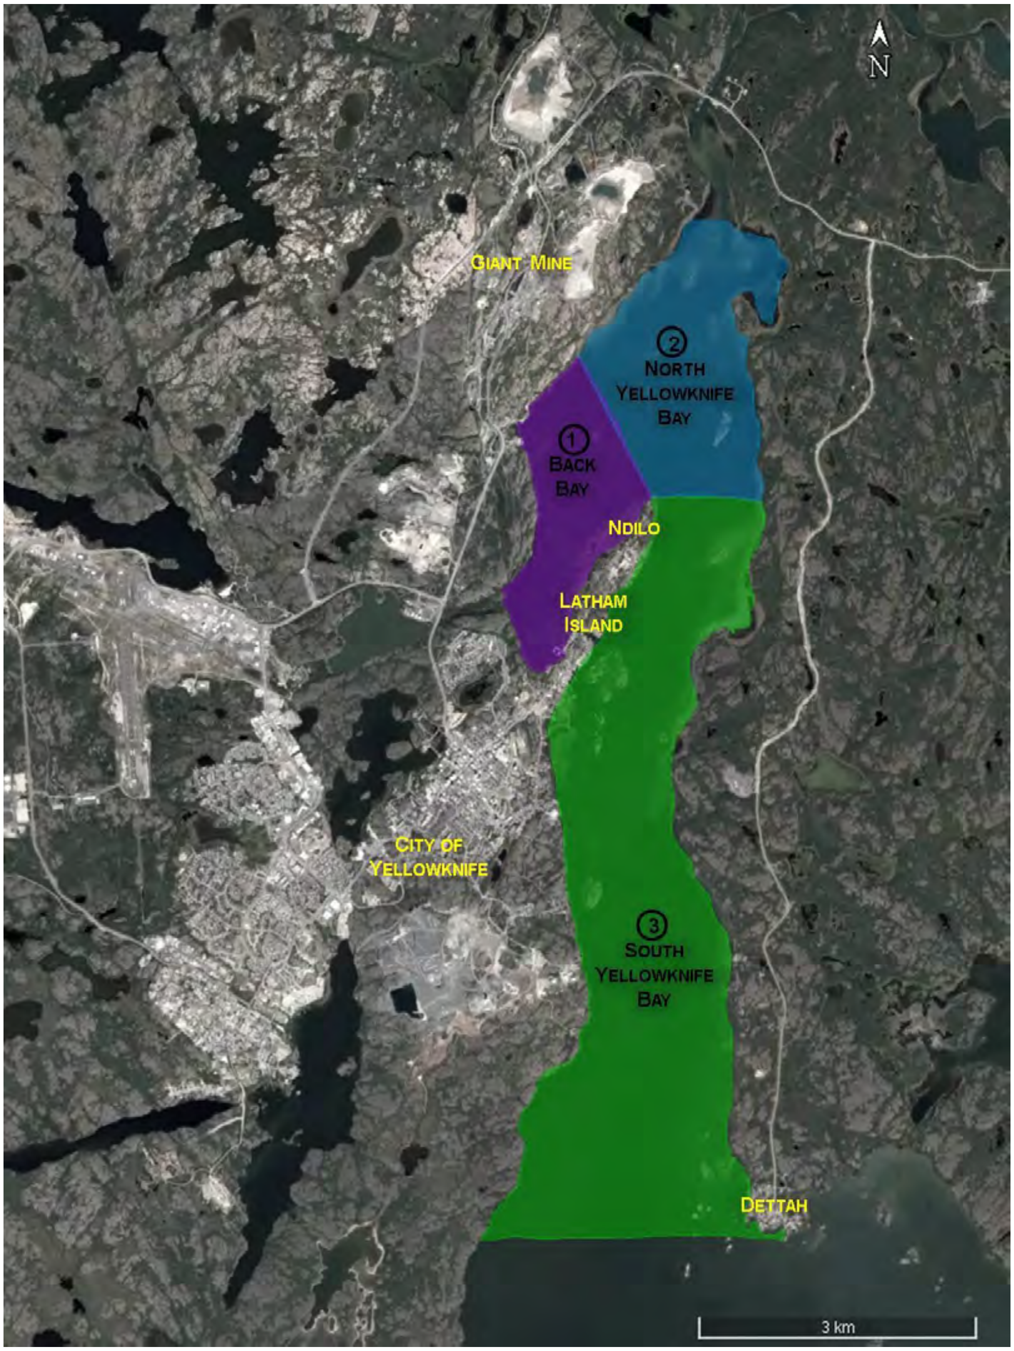


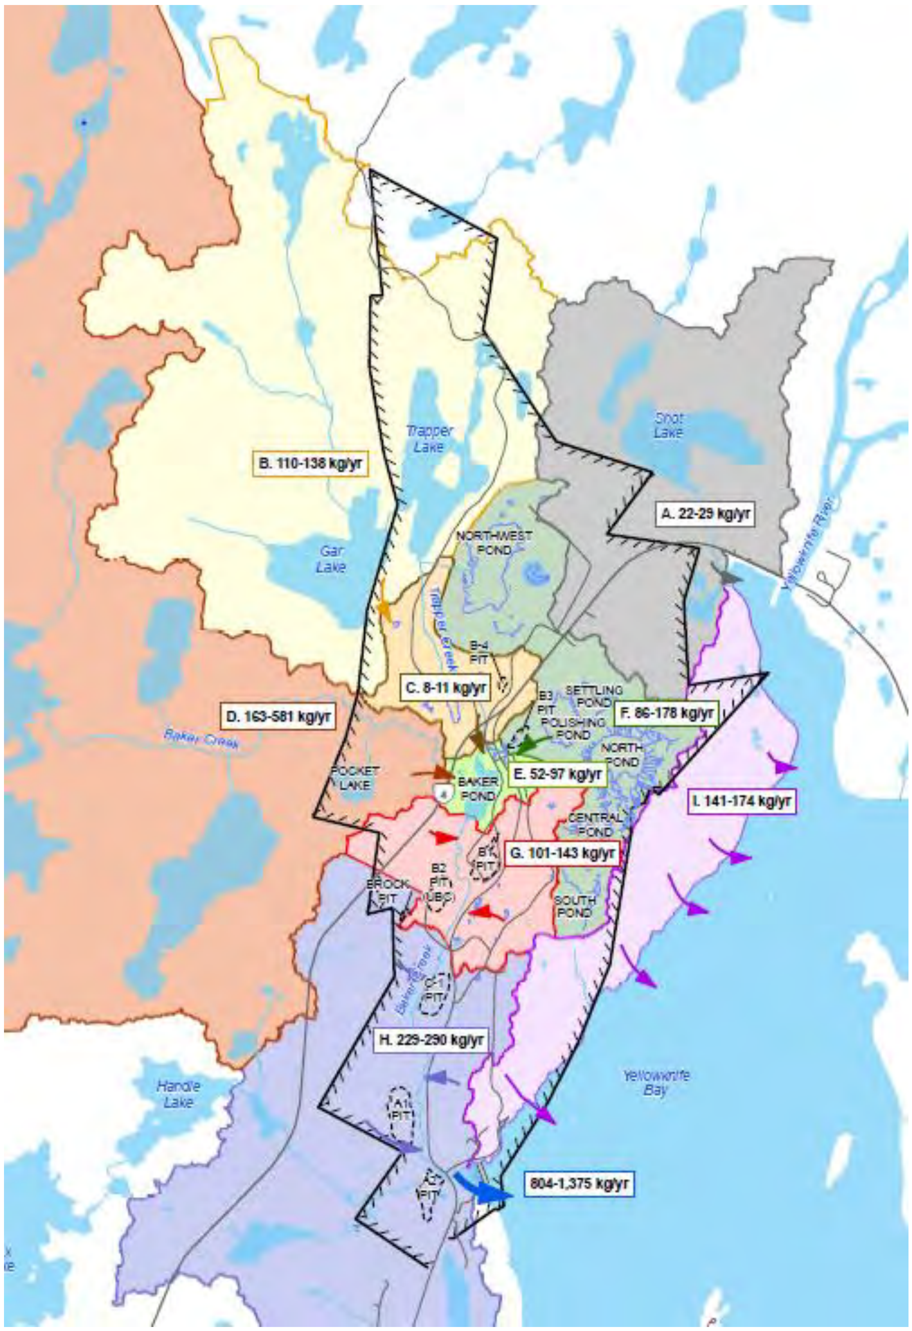
K.5.1 Estimated Loads

The estimated current and predicted future loads to Baker Creek and Yellowknife Bay are provided in the following sections.

K.5.1.1 Loads to Baker Creek

Current (year 2016) loadings for arsenic and antimony were based on information provided by Golder (2017b) for each segment of Baker Creek, as summarized in Figure K.54 and Table K.32.

Figure K.54 Overview of current arsenic loads



From: Golder (2016b).

Table K.32 Summary of current arsenic and antimony loads to Baker Creek

COPC	Current (year 2016) Cumulative Loads (kg/y) [a]				
	Reach 7-11	**Reach 6**	**Reach 4-5**	**Reach 1-3**	**Reach 0** [b]
Arsenic	396	688	810	1063	1063
Antimony	15.4	219	233	374	374
Individual Loads Considered:	Upper Baker Creek WS	Trapper Lake WS Trapper Creek WS ETP Baker Pond	Mill Pond Shallow Seepage	Lower Baker Creek WS	–

Note: a – based on Golder (2017b).
b – Golder (2017b) did not consider individual loads to Reach 0.

Loadings in the future following remedial activities planned for the site were estimated using the current loadings (as presented in Table K.32) with assumptions related to the potential improvements from remedial activities being conducted in areas of the site. The basis of the adjustments to the future loads is provided in the following discussion for each segment.

Reach 7-11

There is no change in loads from Upper Baker Creek watershed assumed for the future. An examination of the concentrations of arsenic at SNP 43-11 over the last few years does not show any trend of decreasing concentration. Therefore, this seems to be a conservative, yet reasonable, assumption.

Reach 6

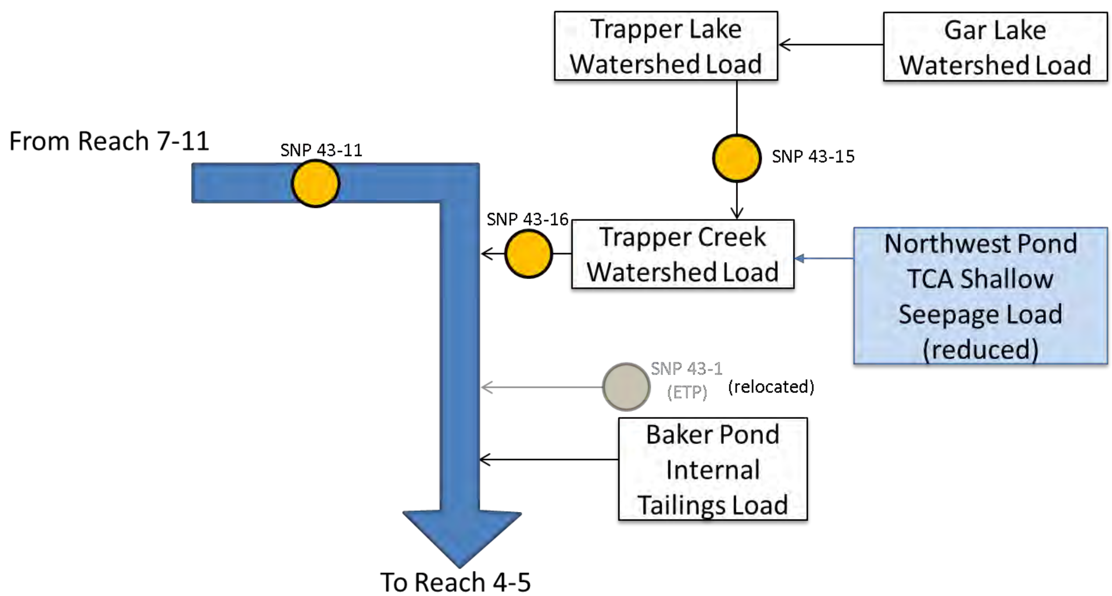
In the future, the loads from Trapper Lake watershed will remain unchanged. The concentrations of arsenic at SNP 43-15 do not indicate a decreasing trend, so this seems to be a reasonable assumption.

With the covering of the Northwest Tailings Pond, the shallow seepage load to Reach 6 (Trapper Creek WS) were assumed to be reduced by 14% based on Table M.7 of the SRK loadings memo for the Giant Mine Developer's Assessment Report (DAR; INAC/GNWT 2010). SRK indicated that concentration in surface runoff from all sources is expected to decrease as readily soluble contaminants are flushed from the system. It was assumed that 50% of the load reduction would be realized at the End of Remediation (2030), 80% would be realized by 2040, and the full load reduction would be in place for the remainder of the modelling period.

In the future, the Effluent Treatment Plant (ETP) will be relocated to Yellowknife Bay near the mouth of Baker Creek; thus, the loads of arsenic, antimony, sulphate, and chloride to Baker Creek from the ETP were removed from Reach 6.

It was assumed that remedial activities in Baker Pond will reduce the internal tailings load from Baker Pond to Reach 6 by 80%. Figure K.55 provides an overview of the future loads to Reach 6.

Figure K.55 Overview of future loads to Reach 6



<u>Reach 4-5</u>

It was assumed that remediation efforts in the old Mill area will reduce the load to Reach 4 and 5 by 14% based on Table M.7 of the SRK loadings memo for the Giant Mine DAR (INAC/GNWT 2010). Similar to above, it was assumed that 50% of the load reduction would be realized at the End of Remediation (2030), 80% would be realized by 2040, and the full load reduction would be in place for the remainder of the modelling period.

<u>Reach 1-3</u>

It was assumed that remedial activities will not change the runoff load from the Giant Mine to Reach 1 to 3.

Reach 0

Consistent with Golder (2017b), individual loads to Reach 0 were not considered. Reductions in loadings to this segment of Baker Creek are assumed to be only from upstream activities.

A summary of the future predicted loads for arsenic and antimony are presented in Table K.33.

Table K.33 Summary of assumed future arsenic and antimony loads to Baker Creek

COPC	Estimated Cumulative Loads (kg/y) [a]				
	Reach 7-11	Reach 6	Reach 4-5	Reach 1-3	Reach 0 [b]
End of Remediation (year 2030)					
Arsenic	396	525	638	891	891
Antimony	15.4	21	33	174	174
Post Remediation – 10 years (year 2040)					
Arsenic	396	524	632	885	885
Antimony	15.4	21	33	174	174
Post Remediation – 30 years (year 2060)					
Arsenic	396	523	628	881	881
Antimony	15.4	21	32	173	173
Post Remediation – 50 years (year 2080)					
Arsenic	396	523	628	881	881
Antimony	15.4	21	32	173	173
Post Remediation – 90 years (year 2120)					
Arsenic	396	523	628	881	881
Antimony	15.4	21	32	173	173
Individual Loads Considered:	Upper Baker Creek WS	Trapper Lake WS Trapper Creek WS Baker Pond	Mill Pond Shallow Seepage	Lower Baker Creek WS	–
Load Assumptions:	No change from current	Trapper Creek WS – reduced 14% ETP – relocated Baker Pond – 80% reduction	Reduced 14%	No change from current	–

Note: a – based on Golder (2017b), with assumptions based on remedial activities. See text for more details.
b – Golder (2017b) did not consider individual loads to Reach 0.

A different approach was used to estimate future concentrations for chloride and sulphate to Baker Creek; concentrations for these COPC were estimated based on measured concentrations, as described in Section K.5.2.

K.5.1.2 Loads to Yellowknife Bay

As mentioned previously, Yellowknife Bay was divided into Back Bay and North Yellowknife Bay, consistent with information provided in SENES (2006). In addition to upstream loads to Yellowknife Bay, horizontal dispersion between the segments also affects the load contributions to each segment. SENES (2006) considered dispersion between the segments, and this was approximated within the current calculations using the information provided in Appendix B of SENES (2006), as follows. The volumetric dispersion coefficient was calculated using Equation K-2 and the segment-specific information provided in Table K.34.

$$E' = \frac{\bar{E} A_c}{l} \tag{K-2}$$

Where:

E' = volumetric dispersion coefficient (m^3/s)
$\bar{E}$ = scale average dispersion coefficient between two connected segments (m^2/s)
A_c = cross-sectional area (depth x width) between two connected segments (m^2)
l = distance between the midpoints of two connected segments (m)

Table K.34 Summary of Yellowknife Bay segments for dispersion calculation

Segment 1	Segment 2	$\bar{E}$ (m^2/s)	A_c (m^2)	l (m)	Calculated E' (m^3/s)	Calculated E' (m^3/y)
Back Bay	North Yellowknife Bay	1.08	1.8×10^4	1300	15	4.7×10^8
North Yellowknife Bay	South Yellowknife Bay	0.1	1.1×10^4	7600	0.15	4.7×10^6

Note: based on information provided in SENES (2006), Appendix B.
South Yellowknife Bay was not explicitly modelled for the current work; however, it was considered for dispersion with North Yellowknife Bay. Water quality in South Yellowknife Bay was assumed to be equal to background water concentrations for the bay for the purposes of the calculation.

The annual volumetric dispersion (E') calculated (Table K.34) was multiplied by the incremental water concentration between two adjacent segments to approximate the load lost or gained from dispersion. The dispersion loads were considered with the upstream loads to estimate the total load to Back Bay and North Yellowknife Bay for the modelled timesteps. These loads are presented in Table K.35 for current conditions.

Table K.35 Summary of current loads to Yellowknife Bay

COPC	Current (year 2016) Cumulative Loads (kg/y)	
	Back Bay	North Yellowknife Bay
Arsenic	1039	674
Antimony	316	307
Chloride	1.2×10^{5} [a]	2.1×10^{6} [a]
Sulphate	3.9×10^{5} [a]	2.3×10^{7} [a]
Individual Loads Considered:	Baker Creek [b] Dispersion with North Yellowknife Bay	Yellowknife River [c] Shot Creek WS [d] Shoreline [d] Dispersion with Back Bay Dispersion with South Yellowknife Bay

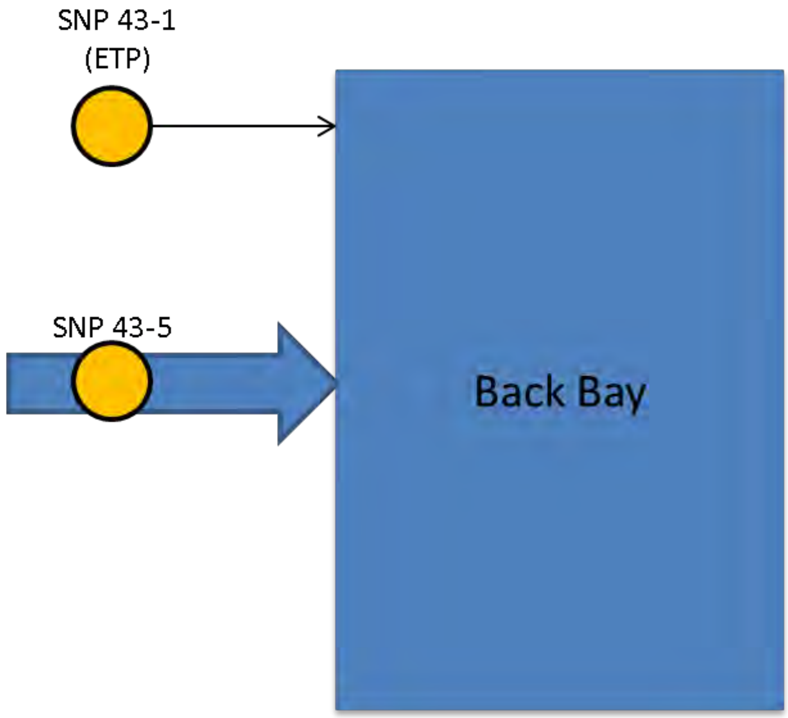
Note: a – Excludes upstream load from Baker Creek.
b – Based on Table K.32.
c – Estimated using Yellowknife River background concentration data and an annual "freshwater inflow" to North Yellowknife Bay of 1.13×10^{9} m3/y specified in SENES (2006).
d – Based on Golder (2017b).

Loadings in the future following remedial activities planned for the site were estimated assuming the relocation of the ETP discharge to Back Bay and remediation of the site to reduce shoreline loads.

ETP Performance

In the future, the ETP will be relocated to Back Bay of Yellowknife Bay near the mouth of Baker Creek (Figure K.56). Flows from AECOM (2012) during the freezing period (630,000 m^3/y) were used for the 10 year period from 2030 to 2040, and, post-freezing, a flow of 404,290 m^3/y was used. Arsenic and antimony concentrations in ETP effluent were assumed to meet drinking water guidelines of 0.01 mg/L and 0.006 mg/L, respectively. At present, it has not been determined what the discharge loads for chloride and sulphate will be for the new effluent treatment plant; therefore, it was assumed that the concentration of chloride and sulphate from the ETP are the same as for the current effluent treatment plant (SNP 43-1). The 95th UCLM of the SNP 43-1 data were used for chloride (444 mg/L) and sulphate (1,170 mg/L) to represent future concentrations from the ETP.

Figure K.56 Relocation of ETP discharge



Shoreline Remediation

The remediation on the surface of the Giant Mine, including the covering of the tailings area, will reduce the runoff to Yellowknife Bay (north segment). It was assumed that the runoff from the Giant Mine to North Yellowknife Bay (Shoreline load) will be reduced by 37% based on Table M.7 of the SRK loadings memo for the Giant Mine DAR (INAC/GNWT 2010). It was assumed that 50% of the load reduction would be realized at the End of Remediation (2030), 80% would be realized by 2040, and the full load reduction would be in place for the remainder of the modelling period.

These assumptions are used in the calculation of future loads to Yellowknife Bay in Table K.36.

Table K.36 Summary of assumed future loads to Yellowknife Bay

COPC	Estimated Cumulative Loads (kg/y) [a]	
	Back Bay	North Yellowknife Bay
End of Remediation (year 2030)		
Arsenic	874	644
Antimony	120	303
Chloride	$4.0x10^{5}$ [a]	$2.1x10^{6}$ [a]

Individual Loads Considered:	Baker Creek[b] ETP – relocated Dispersion with North Yellowknife Bay	Yellowknife River[c] Shot Creek WS[d] Shoreline[d] Dispersion with Back Bay Dispersion with South Yellowknife Bay
Load Assumptions:	ETP performance	Shoreline – 37% reduction

Note: a – excludes upstream load from Baker Creek.
b – based on Table K.33.
c – estimated using Yellowknife River background concentration data and an annual "freshwater inflow." to North Yellowknife Bay of 1.13×10^{9} m^3/y specified in SENES (2006).
d – based on Golder (2017b).

K.5.2 Water Quality

The current and future loads presented in Section K.5.1 were considered along with water quality assumptions to estimate future water quality post-remediation. Current water quality was characterized based on measured data, as presented in Table K.37.

Table K.37 Summary of current water quality

	Water Concentration (mg/L)						
COPC	**Reach 7-11**	**Reach 6**	**Reach 4-5**	**Reach 1-3**	**Reach 0**	**Back Bay**	**North Yellowknife Bay**
Arsenic	0.05	0.39	0.28	0.32	0.12	0.003	0.003
Antimony	0.003	0.29	0.26	0.22	0.12	0.0004	0.0002
Chloride	4.1	364	364[a]	364[a]	516	3.4	3.7
Sulphate	28.2	970	970[a]	970[a]	1511	10.7	11.5
Statistic	95% UCLM	95% UCLM	95% UCLM	95th Percentile	95% UCLM	95% UCLM	95% UCLM

Note: Based on measured data. UCLM – upper confidence limit of the mean.

a – assumed upstream (Reach 6) concentrations in the absence of measured data.

Future water quality for arsenic and antimony were estimated by weighting the current concentrations with the ratio of future to current loads, as shown in Equation K-3. This calculation assumes that the current concentrations are a result of current loadings, and the change in concentration in the future would be proportional to the change in load.

$$C_{wat-future} = C_{wat-current}\frac{Load_{future}}{Load_{current}} \tag{K-3}$$

Where:

$C_{wat-future}$ = future concentration of arsenic and antimony in water (mg/L)
$C_{wat-current}$ = current concentration of arsenic and antimony in water (mg/L)
$Load_{future}$ = future predicted load of arsenic and antimony to segment (kg/y)
$Load_{current}$ = current estimated load of arsenic and antimony to segment (kg/y)

The calculated future water concentrations are presented in Table K.38. For chloride and sulphate concentrations in Baker Creek in the future, the relocation of the ETP will have the biggest impact on concentrations of these constituents. Therefore, future concentrations of chloride and sulphate in Baker Creek were estimated based on recent measured concentrations in Baker Creek during periods where no effluent is being released. The data indicate that 95th percentile concentrations of chloride and sulphate of

4 mg/L and 10 mg/L, respectively. These concentrations were used to represent future water quality in Baker Creek following relocation of the ETP.

Table K.38 Summary of predicted future water quality

COPC	Water Concentration (mg/L)						
	Reach 7-11	Reach 6	Reach 4-5	Reach 1-3	Reach 0	Back Bay	North Yellowknife Bay
End of Remediation (year 2030)

Sulphate	28	10.0	10.0	10.0	10.0	24	11

Note: Estimated based on predicted future loads.

a – based on measured data from Baker Creek when effluent not flowing.

K.5.3 Sediment Quality

Another consideration in the modelling is the potential impact on the sediment. Sediments represent a complex and dynamic environment. Contaminants in the water can be absorbed or adsorbed onto suspended particles and biomass and settle to the bottom.

The concentration in the bottom layer sediment is affected by diffusion into the water column, resuspension, mixing from benthic organisms (bioturbation). Eventually the deposited sediment are buried to where they are less accessible, but changes in oxygen levels and pH can be important considerations.

Remedial activities will also affect arsenic and antimony levels in sediment. The current and future loads presented in Section K.5.1 were considered along with predicted water quality (Table K.38) to estimate future sediment quality post-remediation. Current sediment quality were characterized based on measured data, as presented in Table K.39. Chloride and sulphate are conservative parameters and are assumed to not undergo transfer to sediment and are therefore not included in Table K.39.

Table K.39 Summary of current sediment quality

	Sediment Concentration (mg/kg)						
COPC	**Reach 7-11**	**Reach 6**	**Reach 4-5**	**Reach 1-3**	**Reach 0**	**Back Bay**	**North Yellowknife Bay**
Arsenic	183	1716	2803	2114	1555	1119	709
Antimony	5	385	471	189	325	49	28
Statistic	95% UCLM	95^{th} Percentile	95% UCLM	95% UCLM	95% UCLM	95% UCLM	95% UCLM

Note: Based on measured data. UCLM – upper confidence limit of the mean.

As part of the planned remedial activities, sediments in Baker Creek (Reach 0 to 6) will be dredged, thus removing much of the contaminated material. The resulting concentrations in the sediments were assumed to be around 30 mg/kg for arsenic and 3 mg/kg for antimony; these values are based on Reach 4 post-dredge concentrations.

Sediment concentrations would be expected to increase following dredging activities in the presence of continued loads to the system. This increase was modelled using simplified calculations based on historical relationships between water concentration and sediment concentration (represented by a calculated water-to-sediment distribution coefficient). The consideration of future loading conditions was reflected in the estimated future water concentrations. It should be noted that the relationship between water and sediment concentrations is complex, and this is a simplified approach that provides a rough estimation of future sediment concentrations; however, it is appropriate considering the level of uncertainty in the effect of the remediation plans on the future loadings.

The behaviour of arsenic in sediment is complicated as the change in oxygen levels and presence of iron affects the speciation of arsenic and thus the mobility. The dredging of sediment will remove material, and, thus, detailed consideration of the geochemical behaviour of arsenic in the sediment was not required.

The estimated post-remediation concentrations in sediment were considered within the context of estimates presented in the SENES (2012) letter regarding *Giant Mine Remediation Project: Screening Level Assessment of Post-Remediation Conditions in Baker Creek*. The letter provided simplified calculations to approximate steady-state, or equilibrium, conditions based on the estimated future loads. The calculations presented in SENES (2012) were also verified by application to other sites with model output in steady-state conditions.

Future sediment concentrations post-dredging were estimated using Equation K-4:

$$C_{sed-future} = C_{sed-prev+} \left(C_{wat-future} \times Kd_{wat} \times EF\right) \quad \text{(K-4)}$$

Where:

$C_{sed\text{-}future}$	=	future concentration of arsenic and antimony in sediment (mg/kg)
$C_{sed\text{-}prev}$	=	previous concentration of arsenic and antimony in sediment (mg/kg)
$C_{wat\text{-}future}$	=	future concentration of arsenic and antimony in water (mg/L)
Kd_{wat}	=	approximated water-to-sediment distribution coefficient, based on historical concentrations (L/kg)
EF	=	equilibrium factor (-)

Although steady-state/equilibrium conditions are expected to be reached in Baker Creek and Yellowknife Bay post-remediation, the calculations for sediment consider the changes to sediment over time. Since the distribution coefficient (Kd_{wat}) assumes water and sediment concentrations are in equilibrium, an equilibrium factor (EF) was used to account for the delay for sediment concentrations to reach equilibrium under changing load and water concentration conditions. The EF is considered a reasonable estimate considering the available data (i.e., sediment concentrations observed in Reach 4) and experience from other sites. In the summer of 2006 various activities were taken in Reach 4 including re-alignment, the following information was collected from Reach 4 subsequent to these activities:

- In 2009 a sediment sample was collected from a pool area of Reach 4, the arsenic was measured at 27.9 mg/kg and antimony was measured at <10 mg/kg (Golder 2010).
- In 2011 sediment samples were collected at three depositional areas from Reach 4 (Golder 2013):

	Arsenic (mg/kg)	Antimony (mg/kg)
Baker CreekSS-DEP-11	11.8 (surface)	1.04 (surface)
	23.6 (5-10 cm)	2.87 (5-10 cm)
	11.2 (15-20 cm)	0.96 (15-20 cm)
Baker CreekSS-DEP-12	43.4 (surface)	7.64 (surface)
	18.4 (10-15 cm)	0.76 (10-15 cm)
Baker CreekSS-DEP-13	2370 (surface)	140 (surface)
	1900 (10-15 cm)	280 (10-15 cm)
	1360 (15-20 cm)	201 (15-20 cm)
	604 (25-30 cm)	149 (25-30 cm)

- In 2016 sediment samples were collected from four shoreline locations in Reach 4 (Golder 2016a):

	Arsenic (mg/kg)	Antimony (mg/kg)
16-GIANT-S-01AP	241	53.2
16-GIANT-S-02AP	964	265
16-GIANT-S-03AP	30.7	3.7
16-GIANT-S-04AP	133	7.77

Although there is a substantial amount of uncertainty in this data, it appears that arsenic rose from approximately 30 mg/kg to 300 mg/kg (or approximately 30% of the equilibrium value) in 10 years.

The calculated future sediment concentrations are presented in Table K.40. Chloride and sulphate are conservative parameters and are assumed to not undergo transfer to sediment. Therefore, chloride, and sulphate concentrations in sediment are not included in Table K.40.

Table K.40 Summary of predicted future sediment quality

COPC	Sediment Concentration (mg/kg)						
	Reach 7-11	Reach 6	Reach 4-5	Reach 1-3	Reach 0	Back Bay	North Yellowknife Bay
End of Remediation (year 2030)

Sulphate	-	-	-	-	-	-	-

Note: Estimated based on predicted future water concentrations and loads and calculated water-to-sediment distribution coefficient (Kd_{wat}) of 4,400 L/kg for arsenic and 1,800 L/kg for antimony.
a – for near-shore sediments only.

Sediment concentrations presented in Table K.40 for Back Bay were developed to be representative of nearshore concentrations that humans may be exposed to during wading or other recreational activities. Predictions for the entire Back Bay area, which is more appropriate for assessing exposure of aquatic receptors, were developed by accounting for both near-shore and non near-shore sediment predictions. The EPCs derived to be representative of the entire Back Bay area for use in the ERA were estimated, assuming the nearshore area accounts for roughly 5% of the Back Bay area and that levels in the remaining 95% of the area will improve at approximately 25% for each 100 years; this rate of recovery is based on arsenic predictions presented in the DAR (SENES 2006).

K.6 Post-Remediation Soil Estimates

Remediation of the Giant Mine and Giant Townsite is expected to include:

- installation of a fence to limit human access to the portions of the Giant Mine with the highest levels of arsenic;
- remediation of soil in selected areas of the Giant Mine;
- cover of tailings on the Giant Mine; and
- remediation of soil in the Giant Townsite.

Post-remediation soil concentrations on the Giant Mine were estimated by re-evaluating the current soil dataset for each quadrant and site-wide; by removing samples that are in tailings areas slated for cover; and by reducing the concentration associated with any samples in the remediation areas that were above the remediation target/assumption levels to the target/assumption levels. Derived remediation soil targets/assumptions for the Giant Mine are presented in Table K.41; these values are based on an industrial standard of 340 mg/kg arsenic (GNWT 2003).

The portions of the Giant Site slated for remediation (either soil remediation or tailings cover) within these areas are indicated in Figure K.57 for Trapper Lake North, Figure K.58 for West of Baker Creek, Figure K.59 for East of Baker Creek, and Figure K.60 for South Baker Creek. As can be seen, no remediation is expected to occur in the Trapper Lake North quadrant and very little in West of Baker Creek. The only location expected to have tailings cover is within the East of Baker Creek quadrant. Since it is not expected that the planned fence will limit access to ecological receptors in any substantial way, this remedial activity was assumed to have no effect on the ERA.

The summary statistics for the future soil in the Giant Mine quadrants are presented in Table K.42, Table K.43, Table K.44, and Table K.45. Summary statistics for the resulting combined post-remediation soil dataset for the Giant Mine are shown in Table K.46.

Future soil concentrations within the Giant Townsite area were set equal to the residential soil standard (GNWT 2003) for arsenic, and assumptions were made for the other COPC; these remediation targets/assumptions are presented in Table K.41.

Table K.41 Soil remediation assumptions

COPC	Giant Mine		Giant Townsite
	Tailings Areas	Remediation Areas	
Antimony	Removed all samples from the Tailings Areas.	Remediation Assumption: 34 mg/kg (10% of arsenic). Changed all samples in remediation areas >34 mg/kg to 34 mg/kg.	Remediation Assumption: 16 mg/kg (10% of arsenic). Assumed entire area is at 16 mg/kg.
Arsenic	Removed all samples from the Tailings Areas.	Remediation Target: 340 mg/kg (Site-Specific Industrial Standard, (GNWT 2003). Changed all samples in remediation areas > 340 mg/kg to 340 mg/kg.	Remediation Target: 160 mg/kg (Residential Standard, GNWT [2003]) Assumed entire area is at 160 mg/kg.
Copper	Removed all samples from the Tailings Areas.	No target/assumption, copper samples unchanged.	No target/assumption, copper samples unchanged.
Manganese	Removed all samples from the Tailings Areas.	Remediation Assumption: 476 mg/kg (140% of arsenic). Changed all samples in remediation areas >476 mg/kg to 476 mg/kg.	Remediation Assumption: 220 mg/kg (140% of arsenic). Assumed entire area is at 16 mg/kg.
Zinc	Removed all samples from the Tailings Areas.	No target/assumption, zinc samples unchanged.	No target/assumption, zinc samples unchanged.

Note: The rationale for the assumptions regarding antimony and manganese is presented in Section 3.3.6.3 of the main report.

K.7 Bioavailability/Bioaccessibility

Bioavailability/bioaccessibility assumptions for the purposes of the ERA were made based on the available data and literature. The bioavailability/bioaccessibility of antimony, copper, manganese, and zinc were assumed to be 100%; this is a conservative assumption that was made in the absence of available measured data.

Assumptions for arsenic bioaccessibility were applied to soil, sediment, fish, foliage, and wildlife (e.g., mouse, shrew, hare, waterfowl, ptarmigan, moose, and caribou). Bioaccessibility data for arsenic in soils, sediments, and fish were obtained from samples collected in the study area as part of sampling programs for the GMRP. Bioaccessibility data for arsenic in plants and wildlife were obtained from a publication by Koch et al. (2013) related to bioaccessibility and speciation of arsenic in country foods from contaminated sites in Canada where Giant Mine was part of the study.

Arsenic in other media (e.g., water, aquatic vegetation, benthic invertebrates, terrestrial insects, and non-foliage vegetation) was assumed to be 100% bioavailable in the absence of other information.

The specific assumptions for arsenic bioavailability/bioaccessibility are provided in Table K.47. The samples that went into development of these values are presented and discussed in Appendix F.

Table K.47 Summary of arsenic bioaccessibility values used in the assessment

Media	Location	Bioaccessibility Assumption	Rationale	Data Reference
Sediment	Background Locations	26%	Average of 10 samples from Townsite, assume background same as Townsite.	Golder (2016a), Table 2
Sediment	Baker Creek – Reach 7-11	16.6%	Average of 7 samples.	Golder (2015)
Sediment	Baker Creek – Reach 0-6	44%	Single sample from Reach 6.	Golder (2015)
Sediment	Back Bay	26%	Average of 10 samples from the Townsite area.	Golder (2016a), Table 2
Sediment	Baker Creek/Back Bay Combined	35%	Average of Back Bay and Baker Creek Reach 0-6.	-
Fish	Background Locations	62%	Average of lake whitefish, northern pike, and inconnu from background locations.	Stantec (2014), Appendix C
Fish	Baker Creek – Reach 7-11	62%	Assumed same as background.	Stantec (2014), Appendix C
Fish	Baker Creek – Reach 0-6	61%	Average of lake whitefish and northern pike from the outlet of Baker Creek.	Stantec (2014), Appendix C
Fish	Back Bay	68%	Average of lake whitefish and northern pike from Back Bay.	Stantec (2014), Appendix C
Fish	Baker Creek/Back Bay Combined	65%	Average of Back Bay and Baker Creek Reach 0-6.	-
Waterfowl	Background Locations	50%	Average of hare muscle from uncontaminated areas.	Koch et al. (2013)
Waterfowl	Back Bay	38%	Average of 8 hare samples from contaminated areas.	Koch et al. (2013)
Waterfowl	Baker Creek/Back Bay Combined	38%	Average of Back Bay and Baker Creek Reach 0-6.	-
Waterfowl	Baker Creek – Reach 0-6	38%	Average of 8 hare samples from contaminated areas.	Koch et al. (2013)
Soil	Background Locations	38%	Average of 9 samples representative of undisturbed soils.	Golder (2016c)
Soil	Giant Site	36%	Average of 38 samples from disturbed areas.	Golder (2016d)

Media	Location	Bioaccessibility Assumption	Rationale	Data Reference
Soil	Giant Townsite	30%	Average of 8 samples from the Townsite area.	Golder (2016a), Table 4
Foliage	All	34%	Average of 10 alder and cranberry leaf samples.	Golder (2016a), Table 8
Mouse/Shrew/ Hare/Ptarmigan	Background Locations	50%	Average of hare muscle from uncontaminated areas.	Koch et al. (2013)
Mouse/Shrew/ Hare/Ptarmigan	Giant Site and Townsite	38%	Average of 8 hare samples from contaminated areas.	Koch et al. (2013)
Moose/Caribou	All	50%	Average of hare muscle from uncontaminated areas.	Koch et al. (2013)

K.8 Arsenic Speciation

Arsenic speciation was considered for fish; speciation assumptions were made based on the available data and literature. Organic arsenic, in the form of arsenobetaine, can be assumed to be non-toxic (ATSDR 2007). Therefore, the portion of arsenic assumed to be present as arsenobetaine was removed from the arsenic concentration in order to more accurately represent the potential risks from arsenic.

The specific assumptions for arsenic speciation are provided in Table K.48. The data that went into developing these values is presented in Appendix F.

Table K.48 Summary of fish arsenobetaine values used in the assessment

Location	Arsenobetaine Content	Rationale	Data Reference
Background Locations	36%	Average of lake whitefish, northern pike, and inconnu from background locations.	Stantec (2014), Appendix C
Baker Creek – Reach 7-11	36%	Assumed same as background.	Stantec (2014), Appendix C
Baker Creek – Reach 0-6	46%	Average of lake whitefish and northern pike from the outlet of Baker Creek.	Stantec (2014), Appendix C
Back Bay	54%	Average of lake whitefish and northern pike from Back Bay.	Stantec (2014), Appendix C
Baker Creek/Back Bay Combined	50%	Average of Back Bay and Baker Creek Reach 0-6.	-

K.9 Exposure Estimation and Pathways Calculations

K.9.1 Aquatic Biota and Terrestrial Vegetation

For the aquatic assessment of non-radiological COPC, the evaluation of potential effects is based on a direct comparison of EPCs to aquatic toxicity data. Similarly, potential effects to the benthic invertebrate community are assessed via comparison of sediment concentrations to sediment quality benchmarks. Thus, calculation of species uptake of non-radiological COPC is not needed for the aquatic biota risk assessment component.

The evaluation of potential effects to terrestrial vegetation is done by comparing terrestrial vegetation foliage concentrations to available phytotoxicity information. No intake calculations are required for this evaluation as these vegetation concentrations are estimated using media-to-flesh transfer factors as detailed in Section K.3.

K.9.2 Wildlife

Smaller organisms such as benthic invertebrates are exposed to COPC through sediment or surface water, while larger organisms, such as the wildlife species considered in this sub-section are exposed through multiple pathways.

Intakes for the selected aquatic and terrestrial receptors were estimated up the food chain. Thus, the total intake of a COPC for the selected receptors is the sum of COPC intakes from all the appropriate pathways, including the ingestion of water, sediment or soil, aquatic vegetation, benthic organisms, fish, terrestrial vegetation (e.g., woody vegetation, foliage, and berries/fruits), and prey (e.g., snowshoe hare, waterfowl, etc.). Equation K-5 was used to calculate each of the intake routes as follows:

$$I_n = C_n \times IR_n \times f_{loc} \times CF \qquad \text{(K-5)}$$

Where:

I_n	=	Intake of COPC via “n” exposure pathway (mg/d)
C_n	=	COPC concentration in “n” medium (mg/kg or mg/L for water)
IR_n	=	Intake rate of “n” by the receptor (g/d, or L/d for water)
f_{loc}	=	Fraction of time at site
CF	=	Conversion factor 1.0×10^{-3} (kg/g)

The total intake was then divided by the body weight of the terrestrial receptor for comparison to the TRV which has units of mg per kg body weight per day. The receptor characteristics used to calculate the intakes are provided in Appendix J. For large receptors roaming the site as well as areas off-site, the background contribution to total exposure was accounted. For example, the lynx was evaluated for exposure 50% of the time at the site, while the remainder of the time (50%), the lynx was assumed to be exposed to background concentrations.

There were no measured data for wildlife at the site. Therefore, the amount of COPC ingested through food sources for wildlife was calculated using Equation K-5 and then applying a feed-to-flesh TF to estimate tissue concentrations. Selected TFs for hare and ptarmigan/waterfowl are shown in Table K.49 and Table K.50, respectively.

While the majority of the hare TFs were derived specifically for rabbits, the copper TF was developed for beef; this value was scaled allometrically[1] for using the body weights of the cow and hare (Equation K-6).

For the avian species, Feed-to-flesh TFs for antimony, manganese, and zinc were obtained from N288.1-08 (CSA 2008) and are values derived for poultry flesh. For arsenic and copper, in the absence of any more appropriate TFs, the hare feed-to-flesh TFs were adopted.

The derived TFs are applied as shown in Equation K-7 to calculate the concentration of COPC in the flesh of each ingested species.

$$TF_w = TF_a \left(\frac{BW_w}{BW_a} \right)^{-0.75} \tag{K-6}$$

Where:

TF_w = Feed-to-flesh transfer factor for wildlife (d/(kg ww));
TF_a = Transfer factor for animal available from literature (d/(kg ww));
BW_w = Body weight of wildlife (kg);
BW_a = Body weight of animal (kg).

$$C_{flesh} = I_{total} \times TF_w \tag{K-7}$$

Where:

C_{flesh} = COPC concentration in flesh of ingested mammal (mg/(kg ww))
I_{total} = Intake of COPC via all pathways for ingested mammal (mg/d)

[1] This approach is consistent with the U.S. EPA (1993) approach for developing food and water intake rates for wildlife.

Table K.49 Summary of feed-to-flesh transfer factors for hare

	Feed-to Flesh d/kg ww	Comment
Antimony	4.80E-02	Rabbit TF from N288.1-08 pg 285(CSA 2008)
Arsenic	1.00E+00	Rabbit TF from N288.1-08 pg 285 (CSA 2008)
Copper	9.96E-01	From Baes et al. (1984) for beef; converted to hare using allometric scaling
Manganese	9.80E-02	Rabbit TF from N288.1-08 pg 285 (CSA 2008)
Zinc	6.92E+00	Rabbit TF from N288.1-08 pg 285 (CSA 2008)

Table K.50 Summary of feed-to-flesh transfer factors for waterfowl and ptarmigan

	Feed-to-Flesh d/kg ww	Comment
Antimony	1.00E-01	Poultry meat TF from N288.1-08 pg 285 (CSA 2008)
Arsenic	1.00E+00	Adopted hare feed-to-flesh TF
Copper	9.96E-01	Adopted hare feed-to-flesh TF
Manganese	5.00E-02	Poultry meat TF from N288.1-08 pg 285 (CSA 2008)
Zinc	9.00E+00	Poultry meat TF from N288.1-08 pg 285 (CSA 2008)

K.10 Current Wildlife Concentrations

For the purposes of pathways calculations, concentrations in the flesh of waterfowl, hare, and ptarmigan were required. Concentrations in these species, which were calculated using the approach and feed-to-flesh transfer factors outlined in Section K.9.2, are as follows.

Waterfowl concentrations were taken to be the average of mallard and merganser concentrations calculated using intakes and feed-to-flesh TFs as discussed in Section K.9.2. Site-wide average hare and ptarmigan concentrations were taken to be the average of hare or ptarmigan concentrations for the four quadrants of the site.

Table K.51 Calculated current waterfowl concentrations

Media	Location	Units	Antimony	Arsenic	Comment
Waterfowl	Background	mg/kg ww	$5.8x10^{-3}$	3.7	-
Waterfowl	Back Bay	mg/kg ww	0.05	20	-
Waterfowl	Back Bay/ Baker Creek	mg/kg ww	0.24	31	Average of concentrations for Back Bay and the lower reaches of Baker Creek
Waterfowl	Baker Creek Lower Reach (0-6)	mg/kg ww	0.43	42	-

Table K.52 Calculated current hare concentrations

Media	Location	Units	Antimony	Arsenic	Copper	Manganese	Zinc	Comment
Hare	Background	mg/kg ww	$2.0x10^{-3}$	0.40	0.57	1.8	6.0	-
Hare	Site Average	mg/kg ww	0.04	7.2	1.1	11	6.4	Average of hare concentrations calculated for each of the 4 quadrants

Table K.53 Calculated current ptarmigan concentrations

Media	Location	Units	Antimony	Arsenic	Copper	Manganese	Zinc	Comment
Ptarmigan	Background	mg/kg ww	$2.5x10^{-3}$	0.23	0.34	0.48	5.7	-

K.11 Future EPCs and Wildlife Concentrations

Future EPCs derived for the ERA are presented in Table K.54 and Table K.55 for media related to aquatic receptors and Table K.56 for media related to terrestrial receptors. Surface water and sediment EPCs were based on the modelling detailed in Section K.5, while future soil EPCs were developed using the approach outlined in Section K.6. The rest of the future EPCs were based on site-specific transfer factors presented in Section K.3.

Future wildlife concentrations used in the ERA are presented below for waterfowl (Table K.57 and Table K.58), hare (Table K.59), and ptarmigan (Table K.60); these values were generated using feed-to-flesh TFs as discussed in Section K.9.2.

Table K.54 Future EPCs for aquatic receptors - 2030

Media	Location	Units	Antimony	Arsenic	Chloride	Sulphate	Comment
Surface Water	Back Bay	mg/L	$1.3x10^{-4}$	$2.2x10^{-3}$	12	31	Modelled as discussed in K.5.
Surface Water	Back Bay/ Baker Creek	mg/L	0.03	0.11	7.8	20	Average of the EPCs for Back Bay and the lower reaches of Baker Creek.
Surface Water	Baker Creek Reach 0	mg/L	0.06	0.10	4.0	10	Modelled as discussed in K.5.
Surface Water	Baker Creek Reach 1-3	mg/L	0.10	0.27	4.0	10	Modelled as discussed in K.5.
Surface Water	Baker Creek Reach 4-5	mg/L	0.04	0.22	4.0	10	Modelled as discussed in K.5.
Surface Water	Baker Creek Reach 6	mg/L	0.03	0.30	4.0	10	Modelled as discussed in K.5.
Surface Water	Baker Creek Lower Reach (0-6)	mg/L	0.06	0.22	4.0	10	Average of the EPCs for Reach 0-6.
Surface Water	Baseline - Baker Creek Reach 7-11	mg/L	$2.5x10^{-3}$	0.05	4.1	28	Unchanged from current conditions.
Surface Water	Background - Prosperous/Yellowknife Bay Locations	mg/L	$2.0x10^{-4}$	$5.6x10^{-4}$	NA	NA	Unchanged from current conditions.
Surface Water	Trapper Lake	mg/L	0.02	0.17	NA	NA	Unchanged from current conditions.
Sediment	Back Bay	mg/kg dw	36	875	NA	NA	Modelled as discussed in K.5.
Sediment	Back Bay/ Baker Creek	mg/kg dw	19	452	NA	NA	Average of the EPCs for Back Bay and the lower reaches of Baker Creek.
Sediment	Baker Creek Reach 0	mg/kg dw	3.0	30	NA	NA	Modelled as discussed in K.5.
Sediment	Baker Creek Reach 1-3	mg/kg dw	3.0	30	NA	NA	Modelled as discussed in K.5.
Sediment	Baker Creek Reach 4-5	mg/kg dw	3.0	30	NA	NA	Modelled as discussed in K.5.
Sediment	Baker Creek Reach 6	mg/kg dw	3.0	30	NA	NA	Modelled as discussed in K.5.
Sediment	Baker Creek Lower Reach (0-6)	mg/kg dw	3.0	30	NA	NA	Average of the EPCs for Reach 0-6.
Sediment	Baseline - Baker Creek Reach 7-11	mg/kg dw	5.0	183	NA	NA	Unchanged from current conditions.
Sediment	Background - All Locations	mg/kg dw	1.2	23	NA	NA	Unchanged from current conditions.
Sediment	Background - South Yellowknife Bay	mg/kg dw	1.1	40	NA	NA	Unchanged from current conditions.

K.12 Sample Calculations

Sample calculations are presented here for muskrat in Baker Creek Reach 6 (Table K.61), merganser in Lower Baker Creek (Table K.62), bat in Lower Baker Creek (Table K.63), shrew in East of Baker Creek(Table K.64), hare in East of Baker Creek (Table K.65), and lynx site wide (Table K.66). Results for all locations and scenarios are provided in Appendix M.

Table K.61 Sample Calculation for exposure – muskrat in Baker Creek Reach 6

Baker Creek Reach 6 (Baker Pond) - Current
Muskrat

LIST OF TABLES

APPENDIX L: ECOLOGICAL TOXICITY REVIEW

L.1 Aquatic Biota

The Water Quality Task Group of the Canadian Council of the Ministers of the Environment (CCME) has a protocol to develop the Canadian Water Quality Guidelines for the Protection of Aquatic Life (CCME 2007). The goals of the protocol include (i) accounting for the unique properties of contaminants that influence their toxicity and (ii) incorporating the species sensitivity distribution (SSD) method, which uses all available toxicity data (provided these data pass quality control criteria) in the development of the guideline. The SSD approach has been adopted for the development of the site-specific water quality objectives and is therefore supported by the CCME protocol (CCME 2007).

The first step in the development of the SSD curves was the compilation of relevant aquatic toxicity data. In general, the U.S. EPA ECOTOXicology database (ECOTOX; U.S. EPA 2017) was the primary source of toxicity data, infilled with data from literature searches when required. The ECOTOX database reports toxicity data for a wide range of aquatic species as well as laboratory and field studies. For most chemicals, ECOTOX includes toxicity data in literature from 1972 to the present. All data were quality assured according to the U.S. EPA's criteria, and the system is updated quarterly. The toxicity data were then summarized and screened to meet the following criteria:

- Freshwater tests;
- Chronic;
- LCx, ECx, ICx, MATC endpoints (where x >=10); and
- Inorganic chemical form.

Toxicity tests completed in a saltwater environment with lowest observed effect concentrations/no observed effect concentrations (LOEC/NOEC) reported were excluded from the datasets. Chronic tests were considered to be greater than four days (96 hours). In the development of the SSDs, preference was given to endpoints such as an EC_{20} based on endpoints such as survival, growth, or reproduction.

After the compilation of the dataset, toxicity data were grouped by species. If only one toxicity value was available for a species then that value was used as the toxicity value for the species; however, when multiple toxicity values were available for a species then the geometric mean of the toxicity values was calculated and assumed to represent the toxicity value for that species. The geometric mean was selected instead of the arithmetic mean in order to minimize the bias towards high test results. Species mean values were then ranked from lowest to highest and the percent of species affected was calculated using Equation L-1:

$$\%\ \mathit{Affected} = \frac{\text{Rank - 0.5}}{\text{Number of Species}} \times 100 \qquad \text{(L-1)}$$

After manipulation of the dataset and ranking, SSD curves were developed using either the U.S. EPA (2010) SSD generator (downloaded from the Causal Analysis/Diagnosis Decision Information System [CADDIS]) or the SSD Master V3 tool from the CCME (2013). The U.S. EPA SSD generator applies a log-probit distribution to the dataset to develop the SSD curve, while the SSD Master V3 tool evaluates several distributions to the dataset. The distribution with the best fit was selected for the SSD.

L.1.1 Antimony SSD for Aquatic Toxicity

There were 11 chronic studies with acceptable toxicity information for developing an antimony SSD. There were 4 fish studies, 1 amphibian study, 3 aquatic plant studies and 3 aquatic invertebrate studies. Table L.1 provides a summary of the values used in the development of the SSD while the complete data set for antimony is provided in ATTACHMENT L.1. The toxicity values at the lower end of the curve are the most important studies in the derivation of the protection levels for low effects. The study on population endpoints for the alga *Chlorella vulgaris* (deJong and Roman 1965) was based on a 3 to 4 month timeframe and is deemed to be a chronic endpoint. A NOEC of 32 µg/L, and a NOEC of 64 µg/L are provided in the study. A MATC of 45.3 µg/L was derived from these values. Birge et al. (1980) provides a LC_{10} of 157 µg/L based on a 28 day study in rainbow trout. Birge et al. (1978) also provide LC_{50} and LC_1 values for toads, goldfish, and trout. It is unclear how the LC_1 values were derived and, thus, only LC_{50} values for toad (300 µg/L) and goldfish (11,300 µg/L) were considered from this study.

The SSD curve presented in Figure L.1 was developed using the SSD Master V3 (CCME 2013) model. The gumbel model was selected as the best fit for the antimony data set, particularly for the data in the lower end of the curve. Additional parameters describing the curve are provided in Table L.2. The gumbel model passed the Anderson-Darling fit test, and further information on the fit statistics can be found in the manual accompanying SSD Master V3 (CCME 2013).

Table L.1 Summary of data used to derive SSD for antimony

Species	Group	Endpoint	Effect	Concentration (µg/L)
Chlorella vulgaris	Plant/Algae	MATC	Population	45.3
Oncorhynchus mykiss	Fish	LC10	Mortality	157
Pseudokirchneriella subcapitata	Plant/Algae	NOEC	Population	200
Gastrophryne carolinensis	Amphibian	LC50	Mortality	300
Macrobrachium nipponense	Aquatic Invertebrate	MATC	Physiology	566
Ictalurus punctatus	Fish	NOEC	Gills, Hematology	2191
Pimephales promelas	Fish	MATC	Growth	2284
Fontinalis antipyretica	Plant/Algae	EC50	Physiology	5034
Daphnia magna	Aquatic Invertebrate	MATC	Reproduction	5460
Carassius auratus	Fish	LC50	Mortality	11300
Tubifex tubifex	Aquatic Invertebrate	EC50	Intoxication	678000

Σ	0.0226
A^2	0.204
MSE	0.0025
MSE (lower tail)	0.0137
N	11

Note: For the gumbel model, as determined by SSD Master V3 (CCME 2013).

The CCME protocol for the derivation of water quality guidelines (CCME 2007) considers the 95% protection level (or 5th percentile of the SSD) for defining the guideline from a cumulative SSD, with some additional protection considerations. For setting benchmarks other than water quality guidelines, lower protection levels could be considered, such as the 90% or 80% protection levels, using professional judgement and consideration of site-specific circumstances.

Table L.3 summarizes the concentrations that are protective of 80%, 90%, and 95% of the species, based on the central tendency and upper and lower prediction intervals of the SSD curve. The specific species from the SSD potentially affected at each protection level for the central tendency are also summarized. At the 95% protection level, there are no potentially affected species indicated. At the 90% protection level, green algae may be affected. At the 80% protection level, rainbow trout may also be affected.

Table L.3 Protection levels based on species sensitivity distribution - antimony

Protection Level	Concentration (µg/L)			Species Affected at Central Tendency
	Central Tendency	Upper Prediction Interval	Lower Prediction Interval	
95%	43.2	86.5	21.6	None
90%	77.7	144	41.8	*Chlorella vulgaris*
80%	172	293	102	*Chlorella vulgaris, Oncorhynchus mykiss*

The CCME does not provide a water quality guideline for the protection of aquatic life for antimony. The Ontario Ministry of Environment and Energy (MOEE) prepared a scientific criteria document for antimony (MOEE 1996) that describes the basis for the 20 µg/L proposed guideline. It was determined at that time that there was insufficient aquatic toxicity data available to derive a Provincial Water Quality Objective, so an Interim Provincial Water Quality Objective was developed by dividing the lowest observed effect concentration (7d-LC50) for the toad *Gastrophyne carolinensis* of

300 µg/L by an uncertainty factor of 14.5. The uncertainty factor was derived with consideration of six effects concentrations.

The Predicted No Effect Concentration (PNEC) for antimony in freshwater derived by the European Chemicals Agency (ECHA) is 113 µg/L (ECHA 2017). The PNEC was based on the application of a factor of 10 to the lowest chronic NOEC in their dataset, which was the 28-d growth/length NOEC of 1.13 mg/L for *Pimephales promelas* (Swedish Chemicals Agency 2008). The U.S. EPA (1988) developed a chronic value for the ambient aquatic life water quality criteria for antimony(III) of 30 µg/L. This value was based on the derived acute value of 175 µg/L. The Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC 2000) derived a low reliability trigger value for antimony of 9 µg/L. This interim working level is based on a 96-hr LC50 fish data for *Pimephales promelas* of 9,000 µg/L and an applied factor of 1000. This trigger level is based on short term toxicity data and the determined level is intended to trigger an investigation to develop more appropriate guidelines in the case of an exceedance. The British Columbia Ministry of the Environment (BCMOE 2017) based their freshwater quality guideline on the ANZECC trigger value.

Previously derived values for the protection of aquatic life for antimony range from 9 µg/L to 157 µg/L; the proposed 95% protection level of 43 µg/L based on the derived SSD falls within the lower end of this range and is, therefore, considered suitably conservative, despite the uncertainties introduced by the approach. Furthermore, the protection clause of the CCME (2007) protocol is not invoked.

L.1.2 Arsenic SSD for Aquatic Toxicity

The ECOTOX database (U.S. EPA 2017) was used as the primary source of toxicity data for arsenic. This dataset was supplemented with a number of additional studies including the Vocke et al. (1980) test result for EC_{50} growth endpoints for *Scenedesmus acutus* and Planas and Healey (1978) growth endpoints for *Ochromonas valesiaca* (IC_{20}/LOEC) and *Melosira granulate* (IC_{35}/LOEC), which were considered in the development of the CCME (2001) arsenic water quality guideline. In addition Chen et al. (1999) carried out studies on *Daphnia pulex* for both juvenile and adult life stages. Studies were carried out with both As(III) and As (V). There were differences in concentration-response relationships depending on the endpoint (survival or reproduction) and the form of arsenic. However, the authors noted a decrease of about 28% in cumulative egg production at an arsenic concentration of 10 µg/L. This value was selected as an

EC_{20}/LOEC concentration for reproductive endpoints. This invertebrate is the most sensitive species. A MATC value of 56 µg/L was derived from NOEC and LOEC values for growth for the freshwater algae *Monoraphidium arcuatum* (Levy et al. 2005). The complete dataset is provided in ATTACHMENT L.1 and indicates which data points were included in the development of the SSD. The aquatic toxicity data for arsenic were grouped by species (Table L.4) and the 27 species were ranked.

The SSD curve generated using the data is presented in Figure L.3; this curve was developed using the SSD Master V3 tool (CCME 2013), since the normal model fit the data in the lower and mid sections of the curve better than the logprobit model used in the U.S. EPA SSD generator (2010). The normal model passed the Anderson-Darling fit test and had the best fit in the lower portions of the curve of all included distributions, by visual inspection. Additional parameters describing the curve are provided in Table L.5, and further information on the fit statistics can be found in the manual accompanying SSD Master V3 (CCME 2013).

Table L.6 summarizes the concentrations that are protective of 80%, 90%, and 95% of the species, based on the central tendency and upper and lower prediction intervals of the SSD curve along with species potentially affected at each protection level for the central tendency.

Table L.4 Summary of data used to derive SSD for arsenic

Species	Common Name	Concentration (µg/L)	Endpoint	Geometric Mean (µg/L)	Species Rank	% Affected
Daphnia pulex	Water Flea	10	EC20/LOEC	10	1	2%
Scenedesmus acutus var. acutus	Green Algae	48	EC50	48	2	6%

The CCME water quality guideline for arsenic for the protection of aquatic life is 5 μg/L. This value was derived from a study by Vocke et al. (1980) for growth endpoints for *Scenedesmus obliquus*. The 14 day EC_{50} for growth by dividing the lowest toxicity value of 50 μg/L by a safety factor of 10. It should be noted that this guideline was developed prior to the CCME using the SSD approach to derive water quality guidelines.

L.1.3 Chloride SSD for Aquatic Toxicity

Data for chloride were taken from the CCME chloride surface water quality factsheet (CCME 2011), which is provided in ATTACHMENT L.2. The aquatic toxicity data for chloride were grouped by species (Table L.7) and the 28 species were ranked. The SSD curve generated using the data is presented in Figure L.3; this curve was developed using the SSD Master V3 tool (CCME 2013) since the logistic model fit the data in the lower end of the curve better than the logprobit model used in the U.S. EPA SSD generator (2010). The logistic model passed the Anderson-Darling fit test and had the lowest Anderson-Darling test statistic of all included distributions, indicating best fit.

Further information on the fit statistics can be found in the manual accompanying SSD Master V3 (CCME 2013). Additional parameters describing the curve can be found in Table L.8, and Table L.9 summarizes the concentrations that are protective of 80%, 90%, and 95% of the species, based on the central tendency and upper and lower prediction intervals of the SSD curve. The specific species from the SSD potentially affected at each protection level for the central tendency are also summarized.

Table L.7 Summary of data used to derive SSD for chloride

Species	Common Name	Endpoint	Species Mean Concentration (mg/L)	Species Rank	% Affected
Lampsilis fasciola	Lampmussel	24-hr EC10, glochidia survival.	24	1	2%
Epioblasma torulosa rangiana	Northern Riffleshell	24-hr EC10, glochidia survival.	42	2	5%
Musculium securis	Fingernailclam	60-80 day LOEC, reduced natality.	121	3	9%
Daphnia ambigua	Water Flea	10 day EC10, mortality and reproduction.	259	4	13%
Daphnia pulex	Water Flea	21 day IC10, reproduction.	368	5	16%
Elliptio complanata	Mussel	24-hr EC10, glochidia survival.	406	6	20%

Species	Common Name	Endpoint	Species Mean Concentration (mg/L)	Species Rank	% Affected
Hyalella azteca	Scud	28 day EC25, growth and dry weight.	421	7	23%
Daphnia magna	Water flea	21 day EC25, reproduction.	421	8	23%
Ceriodaphnia dubia	Water Flea	7 day IC25, reproduction.	454	9	30%
Tubifex tubifex	Tubificid Worm	28 day IC10, reproduction.	519	10	34%
Pimephales promelas	Fathead minnow	33 day LC10, survival.	598	11	38%
Salmo trutta fario	Brown Trout	8 day NOEC, survival.	607	12	41%
Villosa delumbis	Mussel	24-hr EC10, glochidia survival.	716	13	45%
Villosa constricta	Mussel	24-hr EC10, glochidia survival.	789	14	48%
Lumbriculus variegatus	Blackworm	28 day EC25, reproduction.	825	15	52%
Oncorhynchus mykiss	Rainbow trout	7 day EC25, embryo viability.	989	16	55%
Lemna minor	Duckweed	96-hr MATC, frond production.	1171	17	59%
Brachionus calyciflorus	Rotifer	48-hr IC10, reproduction.	1241	18	63%
Xenopus laevis	Clawed frog	7 day LC10, survival.	1307	19	66%
Lampsilis siliquoidea	Fatmucket Clam	96-hr EC10, survival of juveniles.	1474	20	70%
Physa sp.	Snail	60 day NOEC, survival.	2000	21	73%
Gammarus pseudopinmaeus	Scud	60 day NOEC, survival.	2000	22	73%
Stenonema modestum	Mayfly	14 day MATC, development.	2047	23	80%
Chironomous tentans	Midge	20 day IC10, growth/biomass.	2316	24	84%
Rana pipiens	Northern Leopard Frog	108 day MATC, survival.	3431	25	88%
Chlorella zofingiensis	Microalgae	28 day MATC, growth.	6066	26	91%
Chlorella minutissimo	Microalgae	28 day MATC, growth.	6066	27	91%
Chlorella emersonii	Microalgae	8-14 day MATC, growth inhibition.	6824	28	98%

The CCME (2011) used the SSD approach to derive the long term freshwater quality guideline of 120 mg/L. This was based on the protection of 95% of the species. This is similar to the value derived in Table L.9.

L.1.4 Sulphate SSD for Aquatic Toxicity

There are no CCME guidelines for sulphate. The BCMOE commissioned the work of Elphick et al. (2011) for the development a revised water quality guideline for sulphate. Sufficient evidence exists to suggest that the toxicity of sulphate reduces with increasing hardness (Elphick et al. 2011), and, therefore, it is appropriate to consider hardness as a toxicity-modifying factor for sulphate aquatic toxicity. However, in contrast to other chemicals that have established toxicity-modifying factors based on hardness (e.g., copper, zinc), an established relationship between toxicity and hardness is not available for sulphate. For sulphate, there are differences in the relationship between sulphate toxicity and hardness for different species (Elphick et al. 2011). Therefore, Elphick et al. (2011) divided the sulphate toxicity data into subsets based on tests conducted in soft water (10-50 mg/L hardness), moderately hard water (75-120 mg/L hardness), and hard water (150-250 mg/L hardness), and developed separate SSD curves for these hardness ranges. This same approach was adopted for the development of an SSD for the Giant Mine.

Because hardness was considered as a modifying factor for toxicity, test results without reported hardness conditions were screened out of the dataset for the development of the species sensitivity distribution for sulphate. While increased sensitivity to sulphate was reported in some tests completed by Elphick et al. (2011) at hardness levels above 250 mg/L, it was concluded that, for some species, the overall ionic strength at high hardness levels causes issues that may not reflect sulphate sensitivity, however, this data was used to generate an SSD curve for hardness above 250 mg/L for use at the Giant Mine.

The Elphick et al. (2011) paper was commissioned by BCMOE "to provide a comprehensive set of toxicological data, generated using standardized test methods, which can be used to establish safe limits for sulfate under varying conditions of hardness." They followed the CCME requirements for establishing Type A Canadian water quality guidelines for the protection of aquatic life, using an SSD approach and used the test species, durations, and endpoints required. Therefore, Elphick et al. (2011) did not consider all available toxicity data for sulphate. Although the Elphick et al. (2011) information was a key data source, a search of the information in the ECOTOX database (U.S. EPA 2017) was conducted to identify potential additional toxicity data. If multiple endpoints were reported within a study, preference was given to EC_{10} and EC_{25}.

Chronic tests were considered to be greater than four days (96 hours), with the exception of the algae *Pseudokirchneriella subcapitata*. A 72 hour test duration is recommended for conducting chronic toxicity tests for *Pseudokirchneriella subcapitata* (EC 2007) and, therefore, data points for algae with a test duration of three days (72 hours) were included in the dataset.

Aquatic toxicity tests completed with sodium sulphate, calcium sulphate, and magnesium sulphate were all considered for the development of the SSD. Data related to potassium sulphate was excluded from the dataset, because potassium exhibits a greater degree of toxicity, as compared with sodium (Mount et al. 1997), and is, therefore, not suitable as a counter-ion in evaluations of the toxicity of anions (Elphick et al. 2011).

The complete dataset is provided in Attachment A and indicates which data points were included in the development of the SSD. After the compilation of the dataset (presented in ATTACHMENT L.1), the data were subdivided based on water hardness, as described above. The next step in the development of the SSD was the grouping of toxicity data by species (Table L.10). Geometric mean concentrations were calculated for each species at each water hardness level. The geometric mean was selected instead of the arithmetic mean in order to minimize the bias towards high test results. Species mean values were then ranked from lowest to highest and the percent of species affected was calculated by dividing the species rank minus 0.5 by the total number of species (from 5 to 9 species, depending on the water hardness level). Additional parameters describing the curve can be found in Table L.11. The SSD curves generated using the data is presented in Figure L.4.

Table L.10 Summary of data used to derive SSD for sulphate

L.2 Wildlife

Toxicity Reference Values (TRVs) for wildlife discussed below are for those constituents of potential concern (COPCs) identified in the soil screening process for which a quantitative evaluation is needed. These COPCs are antimony, arsenic, copper, manganese, and zinc.

L.2.1 FCSAP Toxicity Reference Values

The Federal Contaminated Sites Action Plan (FCSAP 2015) has developed a technical guidance module (Module 7) that recommends values to be used as default wildlife (mammals and birds) TRVs for effects assessments in ecological risk assessments (ERAs). The default wildlife TRVs provided in Module 7 represent a conservative level of protection that is consistent with minimal to low level of effects to common species, and is the level of protection inherent in the Canadian Council of Ministers of the Environment (CCME) soil quality guidelines. Module 7 indicates that the default wildlife TRVs are provided to be used within ERAs on federal contaminated sites where the project scope does not permit the development of site-specific TRVs or the application of a comprehensive weight of evidence approach. Module 7 indicates that the process of developing site-specific TRVs is time consuming and it also is quite costly. Therefore, in lieu of site-specific TRVs, the FCSAP default TRVs are used for this assessment. Module 7 provides TRVs for arsenic, copper, and zinc. Environment Canada provided this document to be used for the Giant Mine risk assessment.

The basis of the wildlife TRVs derived in Module 7 are primarily from data presented in the U.S. EPA risk-based ecological soil screening level (Eco-SSL) documents (U.S. EPA 2005a). Each of the recommended default TRVs have been assigned a quality rating based on the individual TRV's merits, limitations, and uncertainties. Module 7 assigns three grades to the default TRVs (A, B or C).

The TRVs that have been assigned a Grade A by the U.S. EPA are generally consistent with the TRV guidance (FCSAP 2015) and are associated with a high degree of confidence in their overall suitability to be used at federal contaminated sites. The TRVs assigned a grade B have some inherent inconsistencies with the FCSAP TRV guidance, and, therefore, there is a moderate degree of confidence in their overall suitability for use in ERA at contaminated sites. Arsenic and copper TRVs are given a grade A, whereas the zinc TRVs are given a Grade B.

L.2.1.1 Arsenic

Mammals

A default mammalian wildlife TRV of 1.04 mg As/kg-d has been provided in the FCSAP Module 7 (FCSAP 2015). This is based on the highest as the highest bounded NOAEL that was below the lowest bounded LOAEL for endpoints of growth, reproduction, and survival across a set of 55 toxicological studies from the Eco-SSL arsenic document (U.S. EPA 2005a). This highest bounded NOAEL corresponds to a toxicity study by Neiger and Osweiler (1989) where beagle dogs were exposed to sodium arsenite in food over an 8-week study period at dose levels of 0, 1, 2, and 4 mg sodium arsenite/kg bw/day. The dose level of 2 mg sodium arsenite/kg bw/day corresponded to the NOAEL for growth, and the 4 mg sodium arsenite/kg bw/day dose level corresponded to the LOAEL for growth. FCSAP (2015) indicates that this TRV incorporated a range of toxicity data for a variety of species which included rats, mice, rabbits, guinea pigs, dogs, and goats and for a variety of endpoints (specifically reproduction, growth, survival) and, thus, was deemed representative of a broad range of exposure conditions and was given an A grade. The Eco-SSL is based on the NOAEL and, as indicated in Module 7, may be potentially overly conservative. In the selection of the most appropriate default TRV for arsenic, FCSAP (2015) provided a list of candidate mammalian TRVs. Two of the TRVs to note are the geometric mean of the NOAELs for growth, reproduction, and survival for multiple species of 2.9 mg/kg-d and the geometric mean of the LOAELs for growth, reproduction, and survival for multiple species of 5.7 mg/kg-d.

Birds

A default bird TRV of 4.4 mg As/kg-d has been provided in the FCSAP Module 7 (FCSAP 2015). This is based on the second lowest EC20 value for 8 different studies reporting reproduction, growth and mortality studies for mallard ducks, chickens, and quail (CEAEQ 2012). The underlying study for the TRV was a study of arsenic ingestion in chicks which resulted in a reduced growth rate. CEAEQ (2012) applied uncertainty factors to the calculated EC_{20} values to account for duration and mortality. An uncertainty factor of 2 was used to divide EC_{20} values of short duration, and a factor of 5 was used to divide the EC20 for survival endpoints. FCSAP (2015) indicates that this TRV, while based on a limited toxicological data set for three species, provides a level of protection from ingestion studies that is consistent with minimal to low levels of effects and, thus, was given an A grade. In the selection of the most appropriate default TRV for arsenic, FCSAP (2015) provided a list of candidate avian TRVs. Two of the TRVs to note are based on the Eco-SSL arsenic document (U.S. EPA 2005a) and are the geometric mean of the NOAELs for growth, reproduction, and survival of 3.7 mg/kg-d and the geometric mean of the LOAELs for growth, reproduction, and survival of 4.5 mg/kg-d.

L.2.1.2 Copper

Mammals

A default mammalian wildlife TRV of 5.6 mg Cu/kg-d has been provided in the FCSAP Module 7 (FCSAP 2015). This is based on the highest bounded NOAEL that was below the lowest bounded LOAEL for endpoints of growth, reproduction, and survival across a set of 97 toxicological studies from the Eco-SSL copper document. This highest bounded NOAEL corresponds to a toxicity study by Allcroft et al. (1961) in pigs. FCSAP (2015) indicates that this TRV incorporated a range of toxicity data for a variety of species, which included rats, mice, shrews, rabbits, guinea pigs, pigs, mink cattle, horses, and goats and for a variety of endpoints (specifically reproduction, growth, survival) and, thus, was deemed representative of all mammals and was given an A grade. The Eco-SSL is based on the NOAEL and as indicated in Module 7 may be potentially overly conservative. It was noted that in the data set, all bounded NOAELS were found to be, on average, a factor of two times or less than their corresponding LOAEL, indicating a steep dose-response curve. FCSAP (2015) indicated that, based on this steep dose-response curve, the default copper TRV for mammals is likely to provide a sufficient level of protection. In the selection of the most appropriate default TRV for copper, FCSAP (2015) provided a list of candidate mammalian TRVs. One of the TRVs to note is the geometric mean of the NOAELs for growth, reproduction, and survival for multiple species of 38 mg/kg-d.

Birds

A default bird TRV of 4.5 mg Cu/kg-d has been provided in the FCSAP Module 7 (FCSAP 2015). This is based on using Weibull statistical methods to model dose-response curves from 5 different studies involving reproductive endpoints in chickens (CEAEQ 2012). The dose representing a 20% effect level (EC_{20}) was interpolated from the dose-response curves for each of these five studies; the EC_{20}s were divided by an uncertainty factor of 2 to account for the duration of the underlying toxicity test, which ranged from 14 to 70 days. The lowest EC_{20} (Stevenson and Jackson 1980) was selected as the TRV; however, as it is only based on chickens, it may not be representative of all bird species. FCSAP (2015) indicates that this TRV, while being based on a limited toxicological data set for one species (chickens), showed a high confidence based on the quality and relevance of the toxicity data and, thus, was given an A grade. FCSAP (2015) provided a list of candidate avian TRVs. Two of the TRVs to note are based on the Eco-SSL copper document (U.S. EPA 2007a) and are the geometric mean of the NOAELs for growth, reproduction, and survival of 20 mg/kg-d and the geometric mean of the LOAELs for growth, reproduction, and survival of 37 mg/kg-d. Based on this information, FCSAP (2015) acknowledges that the copper TRV may be at the low end of the range of NOAELs and, therefore, provide a level of protection which is well below a 20% effects level.

L.2.1.3 Zinc

Mammals

A default mammalian wildlife TRV of 75.4 mg Zn/kg-d has been provided in the FCSAP Module 7 (FCSAP 2015). This is based on the geometric of 69 NOAEL for endpoints of growth and reproduction from the Eco-SSL zinc document (U.S. EPA 2007b). FCSAP (2015) indicates that this TRV incorporated a data set for a variety of species, which included rats, mice, sheep, pigs, hamsters, and cattle and is considered to be representative of mammals; however, a number of these NOAEL values were unbounded and, thus, the TRV was given a B grade. In the selection of the most appropriate default TRV for copper, FCSAP (2015) provided a list of candidate mammalian TRVs. Two of the TRVs to note are the geometric mean of the NOAELs for growth, reproduction, and survival for multiple species of 87 mg/kg-d and the geometric mean of the LOAELs for growth, reproduction, and survival for multiple species of 290 mg/kg-d.

Birds

A default mammalian avian TRV of 66.1 mg Zn/kg-d has been provided in the FCSAP Module 7 (FCSAP 2015). This is based on the geometric of 43 NOAEL for endpoints of growth and reproduction from the Eco-SSL zinc document (U.S. EPA 2007b). FCSAP (2015) indicates that this TRV incorporated a data set for a variety of species which included chickens, ducks, quail, and turkeys and is considered to be representative of birds; however, a number of these NOAEL values were unbounded and thus the TRV was given a B grade. In the selection of the most appropriate default TRV for copper, FCSAP (2015) provided a list of candidate mammalian TRVs. Two of the TRVs to note are the geometric mean of the NOAELs for growth, reproduction, and survival for multiple species of 83 mg/kg-d and the geometric mean of the LOAELs for growth, reproduction, and survival for multiple species of 190 mg/kg-d.

L.2.2 Other Toxicity Reference Values

There are no default wildlife TRVs for antimony and manganese provided in the FCSAP Module 7 document (FCSAP 2015). Therefore, data from the Eco-SSL documents for antimony (U.S. EPA 2005b) and manganese (U.S. EPA 2007c) were used to develop the TRVs for these COPC.

The Eco-SSL screening process for wildlife toxicity data included a review of primary data sources. Data were preferentially selected from dietary studies (oral exposure) with exposure durations that encompass multiple generations and/or critical life stages and reported population-relevant endpoints (U.S. EPA 2005c). Chronic exposure was generally considered an exposure duration encompassing a significant portion of a species lifespan. However, exposure during sensitive life stages, such as reproduction, may produce severe adverse effects in a few days to as little as a few hours during gestation and embryo development (Sample et al. 1996). Therefore, reproductive studies with exposure durations as short as five days were also considered by the U.S. EPA to represent chronic exposures.

The TRVs were derived from growth- and reproduction-related LOAELs. Where available, the LOAELs were paired with no observable adverse effect levels (NOAELs) for reference purposes. However, NOAEL values were not always available for respective LOAELs in the same studies. A review of the data showed no consistent advantage or disadvantage to limiting the LOAEL data set to LOAELs that are bounded by NOAELs, so the full set of LOAELs was preferentially used to calculate a geometric mean NOAEL (where data allowed) and a geometric mean LOAEL for each test species. Exceptions to this approach were only made in cases where the calculated species geometric mean NOAEL was greater than the species geometric mean LOAEL due to differences in data set size. In these few cases, the species NOAELs and LOAELs were derived only from studies that reported both NOAEL and LOAEL values.

L.2.2.1 Antimony

Mammals

The Eco-SSL document (U.S. EPA 2005b) only has antimony data for growth and reproductive endpoints for rats and mice. This document selects the antimony TRV of

0.059 mg/kg-d based on the highest bounded NOAEL that was below the lowest bounded LOAEL for endpoints of growth, reproduction, and survival across a set of 10 toxicological studies. This highest bounded NOAEL is based on a reproduction end point and corresponds to a toxicity study by Rossi et al. (1987) in gestational female rats exposed to antimony (as antimony trichloride) in three doses (0, 1 and 10 mg/L) in drinking water for 31 days. Adverse effects on progeny (Reduced body weight) were observed at the 10 mg/L dose. Thus, the LOAEL for reproduction is 0.59 mg/kg-d. A review of the data in the Eco-SSL indicates that rats are more sensitive than mice to antimony. There was one growth study in rats exposed to antimony that had a bounded NOAEL. This is a study of rats exposed to antimony in drinking water for 13 weeks (Poon et al. 1998). This resulted in a NOAEL of 5.6 mg/kg-d and a LOAEL of 42 mg/kg-d. The geometric mean of these bounded NOAELs for rats is 0.58 mg/kg-d, which is close to the LOAEL for reproduction from the Rossi et al. (1987) study. There is also a LOAEL for growth obtained from the Rossi et al. (1987) study of 0.059 mg/kg-d. The geometric mean of these three studies is 1.14 mg/kg-d. There is uncertainty in the TRVs discussed here for antimony, as they are based on one species and a limited number of toxicity studies. However, there is a lack of additional data to derive a TRV.

Sample et al. (1996) provided a LOAEL of 1.25 mg/kg-d based on mice exposed to antimony potassium tartarate in drinking water (Schroeder et al. 1968). The median lifespan of the mice were reduced among female mice exposed to the 5ppm dose level, and this was determined to be the chronic LOAEL. Sample et al. divided this LOAEL by an uncertainty factor of 10 to determine a NOAEL of 0.125 mg/kg-d. This study provides values that are in the range of values provided by the Eco-SSL antimony document.

Birds

There are no acceptable avian toxicological studies identified for use in the derivation of TRV for antimony exposure in birds; therefore, no TRV is provided.

L.2.2.2 Manganese

Mammals

The Eco-SSL document for manganese (U.S. EPA 2007c) provides data for growth and reproductive endpoints for a variety of species including rats, mice, hamsters, pigs, rabbits, cattle, water buffalo, and sheep. A NOAEL TRV of 51.5 mg/kg-d was derived based on the geometric mean of 22 NOAEL for endpoints of growth and reproduction from the Eco-SSL manganese document (U.S. EPA 2007c). It is noted that a number of the NOAEL endpoints are unbounded. The lowest bounded LOAEL for reproduction is 71 mg/kg-d based on a gavage study in rats (Rehnberg et al. 1980). The geometric mean for the LOAELs for growth and reproduction from the Eco-SSL document (U.S. EPA 2007c) is 146 mg/kg-d.

Sample et al. (1996) provided a NOAEL of 88 mg/kg-d and a LOAEL of 284 mg/kg-d based on reproductive endpoints for rats exposed to manganese oxide in food (Laskey et al. 1982). Rats consuming 3550 mg Mn/kg food were found to have reduced pregnancy percentage and fertility; however, other reproductive parameters such as litter size, ovulations, resorptions, preimplantation death and fetal weights were not affected. The chronic NOAEL was determined to be 1100 mg Mn/kg food. This study was considered within the Eco-SSL manganese database. As the Eco-SSL document considers a wider number of species the NOAEL is the most appropriate value to use as the TRV.

Birds

The Eco-SSL document for manganese provides data for growth and reproductive endpoints for three species including chickens, turkeys, and quail. A NOAEL TRV of 179 mg/kg-d was derived based on the geometric of 24 NOAEL for endpoints of growth and reproduction from the Eco-SSL manganese document (U.S. EPA 2007c). It is noted that a number of the NOAEL endpoints are unbounded, including all the reproductive studies. The lowest bounded LOAEL for growth is 348 mg/kg-d based on a food study in chickens (Southern and Baker 1983).

Sample et al. (1996) provided a NOAEL of 977 mg/kg-d based on growth and aggressive endpoints for Japanese quail exposed to manganese oxide in food (Laskey and Edens 1985). There was no reduction in growth; however, aggressive behaviour was reduced 25% to 50% relative to controls. The reduction in aggressive behaviour was not considered to be a significant adverse effect. This study was considered within the Eco-SSL manganese database but does not represent a growth or reproductive endpoint and therefore is not a relevant TRV.

L.2.3 Summary of Selected Wildlife TRVs

The TRVs that were selected FCSAP Module 7 document (FCSAP 2015) for mammals and birds are summarized in Table L.13 and include the toxicological endpoint and source. Table L.14 provides the TRVs for antimony and manganese and includes the toxicological endpoint and source.

Table L.13 Summary of default wildlife toxicity reference values for arsenic, copper, and zinc

COPC	Mammals				Birds			
	TRV (mg/kg-d)	Grade	Endpoint	Source	TRV (mg/kg-d)	Grade	Endpoint	Source
Arsenic	1.04	A	Growth	Eco-SSL (U.S. EPA 2005a)	4.4	A	Growth	CEAEQ (2012)
Copper	5.6	A	Growth and survival	Eco-SSL (U.S. EPA 2007a)	4.5	A	Reproduction	CEAEQ (2012)
Zinc	75.4	B	Growth and reproduction	Eco-SSL (U.S. EPA 2007b)	66.1	B	Growth and reproduction	Eco-SSL (U.S. EPA 2007b)

Source: FCSAP (2015) Module 7 – Default Wildlife Toxicity Reference Values (TRVs).

Table L.14 Summary of wildlife toxicity reference values for antimony and manganese

COPC	Mammals			Birds

L.3 Tissue Benchmarks for Wildlife and Terrestrial Plants

The following sections describe the tissue benchmarks that were used to evaluate potential effects in fish, plants, and small mammals.

L.3.1 Aquatic Environment

The fish tissue benchmarks for antimony and arsenic used in the assessment are provided in Table L.15. These benchmarks were obtained from studies that reported whole fish concentrations associated with no and lowest adverse effects levels for survival, reproduction, or growth endpoints (CH2MHill 2015).

For antimony, the benchmarks are based on the exposure of rainbow trout fingerlings to antimony potassium tartrate in water for 30 days. The endpoint was related to survival. The lowest observable effects concentration was based on a 50% reduction in survival of the rainbow trout.

For arsenic, the benchmarks are based on the exposure of rainbow trout fingerlings to arsenate in water for 11 weeks. The endpoint was related to growth. The lowest observable effects concentration was based on significant growth reduction after 28 days exposed to 18 mg/L arsenate. The no observable effects concentration was the highest tissue residue in the fish after 63 days exposed to 9 mg/L arsenate.

Table L.15 Tissue benchmarks selected for evaluation of fish

COPC	No Observable Effects Concentration (NOEC)	Lowest Observable Effects Concentration (LOEC)
	mg/kg ww	
Antimony	5	9
Arsenic	1.5	2

Notes: Benchmarks from CH2MHill (2015).

L.3.2 Terrestrial Environment

L.3.2.1 Foliage Phytotoxic Levels

In order to evaluate potential effects on terrestrial plant populations, measured and predicted vegetation concentrations were compared to available phytotoxicity levels. Available phytotoxicity values for plants are summarized in Table L.16. Kabata-Pendias

(2011) notes that the range of concentrations for trace elements required by plants is very close to concentrations where harmful effects on plant metabolism are observed.

Table L.16 Terrestrial plant phytotoxicity and typical concentrations

COPC	Phytotoxic Foliage Concentration [a] (mg/kg dw)	Critical Level in Leaves and Shoots [b] (mg/kg dw)	Excessive or Toxic Concentration in Mature Leaf Tissue [c] (mg/kg dw)
Antimony	-	-	150
Arsenic	3-10	11-26	5-20
Copper	-	-	20-100
Manganese	-	-	400-1,000
Zinc	500-1,500	160-320	100-400

Notes:
a - Phytotoxic concentration in plant foliage (Langmuir et al. 2004).
b - Upper Critical Level in leaves and shoots of spring barley associated with reduced yield (Davis et al. 1978).
c - Kabata-Pendias (2011).

L.3.2.2 Small Mammal

Tissue concentrations for small mammals were obtained from Puls (1994). The available benchmarks are for organs. For arsenic, the toxic levels are based on rabbits being exposed to 30mg/kg inorganic arsenic in drinking water. The toxic levels for copper are based on exposure of rabbits to dietary copper. As the small mammal concentrations were based on a whole body sample, the use of the organ concentrations are a reasonable surrogate for comparison purposes. Toxic levels from Puls (1994) were adopted as this is the only available source with benchmarks for tissue levels. It is unclear which endpoints the toxic tissue concentrations provided by Puls are based on.

Table L.17 Tissue benchmarks selected for evaluation of small terrestrial mammals

COPC	Toxic Tissue Concentration (mg/kg ww)
Arsenic	6 - 28 liver 5 - 26 kidney
Copper	690 liver 23 kidney

Source: Puls (1994).

It is also noted that a recent study examined biochemical responses to snowshoe hare in the area near Giant Mine compared to a reference location (Amuno et al. 2018b). This paper summarized that hepatic and ocular abnormalities have been associated with chronic arsenic and cadmium exposure in both human and animal studies. The Amuno et al. (2018b) study found that snowshoe hares breeding near the Giant Mine have been chronically exposed to elevated levels of arsenic, as well as cadmium, which has led to increased levels of oxidative stress and perturbation of the antioxidant defense system in exposed animals. Despite the differences in the levels of exposure between the exposed and reference locations, no ocular abnormalities (e.g. such as cataracts or conjunctivitis) were noted, nor any distinct pathological changes in the liver. In addition, Amuno et al. (2018a) provided a preliminary study that suggests that chronic concomitant exposure to arsenic and cadmium may be involved in the etiology of various bone abnormalities, including osteoporosis.

ATTACHMENT L.2

CCME 2011 FACTSHEET FOR CHLORIDE

Canadian Water Quality Guidelines for the Protection of Aquatic Life

CHLORIDE

The chloride ion (Cl^-) is the negatively charged chlorine atom (Cl) (CAS No. 7782-50-5, atomic mass 35.45 g/mol) formed when the chlorine atom picks up one electron. The chlorine atom is a halogen (boiling point of 33.9°C), and never exists in free form in the environment (Nagpal *et al*., 2003). The chloride ion commonly occurs as a salt. Some common chloride salts include NaCl, KCl, $MgCl_2$ (for de-icing of roads and walkways), $CaCl_2$ (used as a dust suppressant on roads), $AlCl_2$ (used in municipal drinking water and wastewater treatment facilities for removal of suspended particles and bacteria from the water), as well as $FeCl_3$ (used at municipal wastewater treatment plants to enhance the removal of phosphorus). Chloride-containing compounds are highly soluble in water (e.g. solubility of NaCl is 35.7g/100g water at 0°C), hence they easily dissociate and tend to remain in their ionic forms (e.g. Na^+ and Cl^-) once dissolved in water. The chloride ion is highly mobile and concentrations in water are not affected by chemical reactions. Hence chloride does not biodegrade, readily precipitate, volatilize, or bioaccumulate. The chloride ion does not adsorb readily onto mineral surfaces and therefore concentrations remain high in surface water and sediment pore water, and low in sediment (Mayer *et al* 1999; Evans and Frick 2001; WHO 2003). Overall, inorganic chloride is generally considered to be a hydrologically and chemically inert substance. However, research by Oberg (2006) has revealed that a large portion of inorganic chloride that is deposited in terrestrial environments is transformed to organic chloride (chlorinated organic matter) in soil or vegetation (with the reverse occurring as well whereby chlorinated organic matter converts to inorganic chloride), although the underlying mechanisms are not fully understood.

It is advised to read the section "Guidance on the Use of Guidelines" found on page 11 of this factsheet before applying the above noted guidelines.

Sources to the environment: The chloride ion is naturally occurring, and therefore detection of increased levels of chloride in surface waters does not necessarily imply an anthropogenic source (although chloride is often used as an indicator of increasing urbanization in a watershed). Natural sources of chloride in aquatic systems include naturally-occurring saline lakes and groundwater discharges from saline aquifers. Canada has many known naturally occurring salt deposits. Major salt deposits (marine evaporite) are found in Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan and Alberta (Dumont 2008; CANMET 1991). Other natural sources include volcanic emanations, sea spray, seawater intrusion

Table 1. Canadian Water Quality Guideline for the Chloride ion[a] for the protection of aquatic life.

	Long-Term Exposure[b] (mg Cl^-/L)	Short-Term Exposure[c] (mg Cl^-/L)
Freshwater	120[d]	640
Marine	NRG	NRG

NRG = no recommended guideline.

[a]Chloride toxicity to freshwater organisms was evaluated using tests with both $CaCl_2$ and NaCl salts.

[b]Derived with mostly no- and some low-effect data and are intended to protect against negative effects to aquatic ecosystem structure and function during indefinite exposures (e.g. abide by the guiding principle as per CCME 2007).

[c]Derived with severe-effects data (such as lethality) and are not intended to protect all components of aquatic ecosystem structure and function but rather to protect most species against lethality during severe but transient events (e.g. inappropriate application or disposal of the substance of concern).

[d]The long-term CWQG may not be protective of certain species of endangered and special concern freshwater mussels (as designated by the Committee on the Status of Endangered Wildlife in Canada, or COSEWIC). This specifically applies to two species; the wavy-rayed lampmussel (*Lampsilis fasciola*) (COSEWIC 2010a) and the northern riffleshell mussel (*Epioblasma torulosa rangiana*) (COSEWIC 2010b) (Table 2). The wavy-rayed lampmussel is indigenous to the lower Great Lakes and associated tributaries, specifically western Lake Erie, the Detroit River, Lake St. Clair and several southwestern Ontario streams. The northern riffleshell mussel is indigenous to the Ausable, Grand, Sydenham and Thames Rivers in Ontario, as well as the Lake St. Clair delta. Discussion with provincial regulators should occur if there is a need to develop more protective site specific values.

Table 2. 24h EC_{10} values (survival of glochidia) for 2 species of COSEWIC assessed freshwater mussels

COSEWIC Assessed Species	24h EC_{10} (mg Cl^-/L).	95% Confidence Intervals
Lampsilis fasciola Wavy-rayed lampmussel (COSEWIC special concern)	24 (Bringolf, 2010)	-79[1], 127
Epioblasma torulosa rangiana Northern riffleshell mussel (COSEWIC endangered)	42 (Gillis, 2009)	24, 57

[1] The negative lower fiducial limit is an artefact of the statistics. Biologically this can be interpreted as meaning that a 10% effect can be observed between a concentration of 0 and the upper 95% confidence limit. Therefore, the effect is not significantly different from the control (no-effect concentration) and could be due to natural variability.

in coastal areas (NRC 1977), as well as wildfires and logging (remobilization of major ions in lake watersheds impacted by these perturbations) (Pinel-Alloul *et al* 2002). Seawater salt concentrations are approximately 35,000 mg/L of which approximately 55% is chloride, which equates to 19,250 mg Cl^-/L (Evans and Frick 2001). Chloride compounds from anthropogenic sources enter the aquatic ecosystem through various pathways, such as wastewater effluents, stream inflow, road or overland runoff, groundwater inputs, and leaching from contaminated soils (Evans and Frick, 2001). A major non-industrial anthropogenic source of chloride to densely populated regions of Canada (e.g. southern Ontario and Quebec) is the application and storage of road salt for snow and ice control in the winter (97% of road salt used in Canada is in the form of NaCl, 2.9% in the form of $CaCl_2$, and 0.1% as $MgCl_2$ and KCl) (Chapra *et al.*, 2009; L. Trudell, Environment Canada, pers. comm.). Road salt is the single largest source of chloride entering Lake Ontario from local sources (Evans and Frick 2001), and is also a significant source of chloride loading into Lake Simcoe in Ontario (Winter *et al.*, 2011). During the 1997 to 1998 winter, Morin and Perchanok (2000) estimated that 2,950,728 tonnes of chloride was released into the Canadian environment as a result of road salt (as NaCl) and dust suppressant (as $CaCl_2$) application. The provinces with the most chloride use on roadways were Ontario (1,148,570 tonnes) and Quebec (950,444 tonnes). However, Nova Scotia was found to have the highest loading per unit area of the province (230,182 tonnes) (Morin and Perchanok 2000). In comparison, the estimated discharge of chloride into Ontario waters in 2008 from municipal wastewater treatment plant effluent was 175,000 tonnes (M. Manoharan, Ontario Ministry of the Environment, pers. comm.). An often unquantified but likely significant use of road salt is private de-icing operations such as applications onto sidewalks, driveways, and parking lots (Perera *et al* 2009; Chapra *et al* 2009). Elevated concentrations of chloride associated with de-icing have been documented in groundwater, wetlands, streams, and ponds adjacent to snow dumps and salt-storage areas, and also those draining major roadways and urban areas in Canada (Evans and Frick 2001). Other anthropogenic sources include disposal of snow cleared from roadways, application of chloride brine solutions for dust suppression in the summer, water softeners, industrial effluent, domestic sewage, landfill leachate, irrigation drainage (Evans and Frick 2001), and industrial site drainage. Chloride (from inorganic salts) is not tracked by Environment Canada's National Pollutant Release Inventory. Ontario tracks chloride releases from a small number of sectors (e.g. electric power generation, industrial minerals, inorganic chemical, metal mining) covered under MISA (Municipal/Industrial Strategy for Abatement) regulations, but not from other industries (Chapra *et al* 2009).

Ambient Concentrations: Ambient chloride concentrations in the Atlantic region (Newfoundland and Labrador, Nova Scotia, New Brunswick and Prince Edward Island) of Canada are normally <10 mg/L in inland lakes, with concentrations as high as 20 to 40 mg/L in lakes located closer to coastal areas (Mayer *et al* 1999; Evans and Frick 2001; D. Parent, Environment Canada, pers. comm.). Unimpacted lakes on the Canadian shield of Canada's central region (Quebec and Ontario) have measured chloride concentrations of <1 to 7 mg/L, with higher concentrations (10 to 30 mg/L) measured in the lower Great Lakes and the St. Lawrence River (Evans and Frick 2001). Chloride concentrations above background are commonly detected in densely populated areas (e.g. small urban watersheds) where road densities are high, and in fact, chloride concentrations are a commonly used indicator of increasing urbanization. Monitoring of Sheridan Creek in Ontario (pre-1980 to 2007), located in a fully-developed urban area containing a dense road network, measured chloride ranging from 14.5 to 5,320 mg Cl^-/L (median of 292 mg Cl^-/L) (OMOE 2009). Real-time monitoring of a Lake Ontario tributary (Cooksville Creek) in a highly urbanized watershed (Mississauga, Ontario) showed chloride levels exceeding that of seawater, with measurements made in February 2011 reporting chloride as high as 20,000 mg/L (K. vander Linden, Credit Valley Conservation Authority, pers. comm.). In the case of Canada's prairie region (Manitoba, Saskatchewan, and Alberta), low chloride concentrations (<5 mg/L) are reported in lakes located in the northern portions of the provinces, outside of the Interior Plains region. The Interior Plains region, which covers the southern portion of the prairie provinces, is an area with naturally elevated salinity (high total dissolved solids) (CEPA 1999). This salinity is usually due to high concentrations of sodium (mean range of 92 to 31,311 mg/L), bicarbonate (mean range of 427 to 16,352 mg/L) and sulphate (mean range of 2,305 to 108,069 mg/L), although chloride concentrations (mean range of 71 to 3,793 mg/L) are still significantly higher than other areas (Last and Ginn, 2005). For the Pacific region (British Columbia), the chloride concentration in unimpacted water bodies is <5 mg/L. However, several lakes in the southern interior plateau had measured chloride concentrations >100 mg/L (Evans and Frick 2001). Water quality monitoring data in the Yukon showed that dissolved chloride concentrations are low, ranging from 0.1 to 4.6 mg/L (Environment Canada 2009).

Chloride and Salinity of Canadian Surface Waters: Salinity is a measure of the total salt composition of water, with freshwater lakes being dominated by the cations Ca^{2+}, Mg^{2+}, K^+ and Na^+ and the anions HCO_3^-, CO_3^{2-}, SO_4^{2-} and Cl^- (Wetzel 1983). Water is classified according to salinity. Freshwater lakes are those with less than 500 mg/L salinity. The salinity of sub-saline lakes ranges from 500 to 3,000 mg/L, and the salinity of saline lakes exceeds 3,000 mg/L (Evans and Frick 2001). When chloride salts are added to freshwater systems (e.g. through the application of road salt), the salts dissolve and dissociate into respective ions and directly increase the salinity of the receiving system (Evans and Frick 2001). Salinity is a key factor in controlling survival and distribution of both freshwater invertebrates and fish (Holland *et al* 2010). Naturally saline lakes within Canada (commonly dominated by SO_4/CO_3 and relatively rarely by Cl) are systems with naturally low biodiversity (Derry *et al* 2003). Most freshwater organisms found within these systems are stenohaline (have a narrow range of tolerance to changes in salinity), although some organisms are euryhaline (able to tolerate and adapt to a wide range of salinities) (Derry *et al* 2003; Holland *et al* 2010).

Assessment of Road Salt under the Canadian Environmental Protection Act: The Priority Substances List Assessment Report for Road Salts was published on December 1, 2001 (Environment Canada 2001). The report concluded that road salts that contain inorganic chloride salts with or without ferrocyanide salts (anti-caking agent) have adverse impacts on the environment and are therefore toxic under subsections 64(*a*) and (*b*) of the *Canadian Environmental Protection Act, 1999* (CEPA 1999). This decision has led to the publication in April 2004 of a Code of Practice for the Environmental Management of Road Salts. This Code of Practice is aimed at helping municipalities and other road authorities better manage their use of road salts in a way that reduces the harm they cause to the environment while still maintaining road safety.

Several studies have indicated that even when road salt application decreases, surface water monitoring of chloride concentrations does not show an associated decrease in chloride concentration (Meriano *et al* 2009; Kilgour *et al* 2009). This is attributed to subsurface storage of chloride and the lag effect of chloride entering surface water systems, resulting in increased baseflow[1] chloride concentrations. Sensitive species located in surface waters within rapidly-urbanizing watersheds or fully-developed watersheds are at risk of being adversely impacted by increased baseflow chloride levels. Increased chloride in surface water has also been linked to reducing the vertical mixing of surface waters by way of changing the density gradient in lakes. This phenomenon is referred to as meromixis (layers of water that do not experience complete overturn or complete vertical mixing). One of the outcomes of stable stratification of deep and surface water layers is that the deep layer (monimolimnion) can become quite depleted of oxygen. The concentration of dissolved oxygen in the monimolimnion of a meromictic lake can be less than 1 mg/L, while the surface layer (mixolimnion) may have concentrations of 10 mg/L or higher (Lampert *et al.* 1997). Low dissolved oxygen concentrations in the monimolimnion will limit the survival of aquatic life in this layer. In addition to chloride (saline) input, other variables are also involved in inducing chemical-based density stratification between lower and upper water layers leading to a resistance of vertical mixing (e.g. lake morphometry, water residence time, watershed topography and wind fetch) (Wetzel 2001).

Toxicity: Chloride toxicity tests have been conducted through the addition of chloride salts such as sodium

[1] Streamflow which is not a direct result of rainfall or melting snow. Baseflow is the streamflow which is sustained primarily through ground-water discharges.

chloride, calcium chloride, magnesium chloride and potassium chloride. Results of tests with potassium and magnesium chloride suggest toxic effects observed are due to the potassium and magnesium cation, rather than the chloride anion. Conversely, it has been observed that the toxic effects of calcium chloride and sodium chloride are likely due to the chloride anion. Generally speaking, the effect concentrations resulting from exposures to KCl and $MgCl_2$ salts are lower (e.g. more toxic) than the effect concentrations resulting from exposures to $CaCl_2$ and NaCl salts (when effect concentrations are assessed on a chloride anion basis). For example, the fathead minnow 96-h LC50 effect concentration resulting from exposure to a KCl salt, a $MgCl_2$ salt, a $CaCl_2$ salt and a NaCl salt was 419 mg Cl/L, 1579 mg Cl/L, 2958 mg Cl/L and 3876 mg Cl/L, respectively (Mount et al., 1997). Therefore, the approximate order of chloride salt toxicity to freshwater organisms is KCl > $MgCl_2$ > $CaCl_2$ > NaCl (Mount *et al* 1997). Based on these observations, chloride toxicity to freshwater organisms was only evaluated using tests with $CaCl_2$ and NaCl in order to ensure that the effect concentrations utilized for chloride guideline derivation were derived from tests where effects were based on the chloride anion, and not on associated cations.

Freshwater organisms are generally hyperosmotic (internal solute or salt concentration is higher when compared to the surrounding water) and thereby have to continuously excrete water (with some solute loss) to maintain equilibrium (Holland *et al* 2010). Freshwater organisms therefore have to take up ions to replace the ones lost, which can result in elevated energy expenditures until a threshold of intolerance is reached (Holland *et al* 2010). Increasing chloride in surface waters results in increased salinity, thereby affecting the ability of some organisms (stenohaline more so than euryhaline) to effectively osmoregulate, which could in turn affect endocrine balance, oxygen consumption following chronic exposures, and overall changes in physiological processes (Holland *et al* 2010). In both invertebrates and fish, the main site of osmoregulation is the gill, which is also the site of active uptake of lost salts. The sodium pump (Na^++K^+-ATPase) is the main mechanism for moving ions across gills in aquatic animals. The mechanism of osmoregulation used is dependent on the life stage of the organism. For example pre-larval fish osmoregulate largely through the skin, whereas larval stages regulate through the gills (Varsamos and Charmantier, 2005). Insects possess a network of Malpighian tubules lined with secretory cells extending throughout much of the body cavity which is involved in the reabsorption of ions (Dettner and Peters 1999). In the case of spotted salamander (*Ambystoma maculatum*) egg clutches, disruption in osmoregulation has not been determined but is likely related to chemical changes in the egg capsule (perivitelline) membrane, as has been documented in egg clutches exposed to highly acidic conditions (Karraker and Gibbs 2011). As with exposure to acid, high chloride concentrations may result in making the egg capsule membrane more rigid, reducing permeability, and therefore impacting the ability for water uptake (Karraker and Gibbs 2011).

Toxicity Modifying Factors: Some studies have indicated that increased hardness may have an ameliorating effect on the toxicity of chloride. One long-term study by Elphick *et al.* (2011) assessed the effect of hardness (10, 20, 40, 80, 160, 320 mg/L as $CaCO_3$) on sodium chloride toxicity to the water flea *Ceriodaphnia dubia* during a 7-day exposure. An approximate 4-fold difference was observed in the 7-day $IC_{25/50}$ (reproduction) effect concentrations, and a 9-fold difference in 7-day LC_{50} concentrations over the hardness range tested. Gillis (2011) exposed glochidia of the freshwater mussel *Lampsilis siliquoidea* to water of varying hardness (47, 99, 172, 322 mg/L as $CaCO_3$). An approximate 2.5-fold difference in 24-hour EC_{50} (glochidia survival) values was observed over the hardness range tested. GLEC and INHS (2008) also conducted some short-term exposures indicating the existence of a hardness-chloride toxicity relationship for the water flea *Ceriodaphnia dubia*, the fingernail clam *Sphaerium simile*, the oligochaete *Tubifex tubifex* and the aquatic snail *Gyraulus parvus*. Insufficient data were available to develop a hardness relationship for chronic toxicity and thus, a hardness-based CWQG was not developed. CCME will re-visit the chloride guidelines when sufficient studies are available. Jurisdictions may choose to derive site-specific hardness-adjusted water quality criteria (or objectives) where appropriate.

Water Quality Guideline Derivation: Both the freshwater short and long-term Canadian water quality guideline (CWQG) for the chloride ion for the protection of aquatic life were developed based on the CCME protocol (CCME 2007) with the statistical (Type A) approach.

Short-term Freshwater Quality Guidelines: Short-term exposure guidelines are derived with severe-effects data (such as lethality) of defined short-term exposure periods (24 to 96-hour). These guidelines identify estimators of severe effects to the aquatic ecosystem and are intended to give guidance on the impacts of severe but transient situations (e.g., spill events to aquatic receiving environments and infrequent releases of short-lived/non-persistent substances). Short-term benchmark concentrations *do not* provide guidance on protective levels of a substance in the aquatic environment, as short-term benchmark concentrations are levels that *do not* protect against adverse effects.

The minimum data requirements for the Type A short-term benchmark concentration approach were met and a total of 51 data points (14 of which are EC_{50} values) were used in the derivation of the value (Table 3). Each species for which appropriate short-term toxicity data were available was ranked according to sensitivity. Intra-species variability was accounted for by taking the geometric mean of the studies considered to represent the most sensitive lifestage and endpoint.

The log-Normal model provided the best fit of the five models (Normal, Logistic, Weibull, Gompertz, Fisher-Tippett) tested (Figure 1). The equation of the Normal model is:

$$f(x) = \frac{1}{2}\left(1 + erf\left(\frac{x-\mu}{\sigma\sqrt{2}}\right)\right)$$

where, for the fitted model: x = log (concentration) of chloride (mg/L), y is the proportion of species affected, μ = 3.4390, σ = 0.3841 and *erf* is the error function (a.k.a. the Gauss error function). The short-term SSD is shown in Figure 1 and summary statistics are presented in Table 4. The 5th percentile on the short-term SSD is 640 mg Cl^-/L which is essentially within the range of the data (to which the model was fit). Therefore the 5th percentile and its fiducial limits (FL) (boundaries within which a parameter is considered to be located) are interpolations.

Two data points fall below the short-term SSD 5th percentile value of 640 mg Cl^-/L. This includes the 24-hour EC_{50} of 244 mg Cl^-/L for the mantle lure spawning freshwater mussel (glochidia lifestage) *Epioblasma torulosa rangiana* (COSEWIC endangered) (Gillis, 2011), and the 48-hour EC50 (immobilization) of 621 mg Cl^-/L for the water flea *Daphnia magna* (Khangarot and Ray, 1989). Two other COSEWIC assessed species of freshwater mussels are also represented on the short-term SSD, with all data points above the 5th percentile value. This includes the glochidia 24-hour EC_{50} of 746 mg Cl^-/L for the COSEWIC special concern wavy-rayed lampmussel (*Lampsilis fasciola*) (Valenti *et al* 2007; Gillis 2011; Bringolf *et al* 2007), and the juvenile 96-hour EC_{50} of 1,815 mg Cl^-/L for the COSEWIC endangered rainbow mussel (*Villosa iris*) (Wang and Ingersoll 2010). Both *L. fasciola* and *V. iris* are mantle lure spawners. Based on the short-term SSD, short-term exposures to levels of chloride exceeding the benchmark concentration of 640 mg Cl^-/L *may* pose the greatest hazard to the glochidia life stage of certain freshwater mussel species and to *Daphnia magna*. Note that meeting the proposed long-term guideline will protect from severe effects.

It is worth noting that glochidia of the COSEWIC special concern mussel *Lampsilis fasciola* are significantly more sensitive when tested in reconstituted laboratory water compared to natural river waters. Two separate tests derived 24-hour EC_{50} values of 113 mg Cl^-/L and 285 mg Cl^-/L for *L. fasciola* when conducted in moderately hard reconstituted water (99 mg/L as $CaCO_3$) (Gillis 2011). In comparison, the 24-hour EC_{50} values for *L. fasciola* tested in water collected from 4 different rivers in Ontario, Canada were 1,559 mg Cl^-/L (Grand River, hardness 278 mg/L as $CaCO_3$), 1,313 mg Cl^-/L (Sydenham River, hardness 292 mg/L as $CaCO_3$), 1,391 mg Cl^-/L (Maitland River, hardness 322 mg/L as $CaCO_3$) and 1,265 mg Cl^-/L (Thames River, hardness 306 mg/L as $CaCO_3$) (Gillis 2011). The ameliorating effect of natural water chemistry was attributed to more than just a difference in water hardness. A separate test looking at the impact of water hardness on chloride toxicity was conducted with *Lampsilis siliquoidea* (Gillis 2011). Resulting 24-hour EC_{50} values were 763, 1430, 1962 and 1870 mg Cl^-/L in soft (47 mg/L as $CaCO_3$), moderately hard (99 mg/L as $CaCO_3$), hard (172 mg/L as $CaCO_3$) and very hard (322 mg/L as $CaCO_3$) reconstituted water, respectively. The 4-fold difference in 24-hour EC_{50} values obtained for *L. fasciola* in natural river water, when compared to reconstituted water, is much larger than would be expected from hardness alone (as determined with *L. siliquoidea*), implying that other water chemistry variables are contributing to the reduction of chloride toxicity in natural waters. Short-term benchmark concentrations (as well as long-term CWQGs) are derived using laboratory-based studies which use reconstituted water to ensure consistency and the ability to compare results between studies. One disadvantage of using reconstituted waters is that results may not necessarily reflect organism responses in natural waters. Natural waters, on the other hand, contain variable water chemistry in addition to other potential contaminants resulting in variable toxic impacts to

Table 3. Endpoints used to determine the freshwater short-term CWQG for the chloride ion.

[b]Based on testing with $CaCl_2$ salt (all others based on testing with NaCl salt).

biotic receptors. Therefore, short-term benchmark concentrations (as well as long-term CWQGs) may be relatively conservative values.

Therefore, the s hort-term exposure benchmark concentration indicating the potential for severe effects (e.g. lethality or immobilization) to senstive freshwater life during transient events is 640 mg Cl^-/L for the chloride ion.

Table 4. Short-term freshwater CWQG for the chloride ion using the SSD method.

	Concentration
SSD 5th percentile	**640 mg Cl^-/L**
SSD 5th percentile, 90% LFL (5%)	605 mg Cl^-/L
SSD 5th percentile, 90% UFL (95%)	680 mg Cl^-/L

Long-term Freshwater Quality Guideline: Long-term exposure guidelines identify benchmarks in the aquatic ecosystem that are intended to protect all forms of aquatic life for indefinite exposure periods. Long-term exposure guidelines are derived using long-term data (≥7-day exposures for fish and invertebrates, ≥24-hour for aquatic plants and algae).

The minimum data requirements for the Type A guideline approach were met and a total of 28 data points were used in the derivation of the guideline (Table 5). Each species for which appropriate long-term toxicity data was available was ranked according to sensitivity. All datapoints were taken from single studies, therefore none of the concentrations listed in Table 5 are geometric means.

The log-Logistic model provided the best fit of the five models (Normal, Logistic, Weibull, Gompertz, Fisher-Tippett) tested (Figure 3). The equation of the Logistic model is:

$$y = 1/[1+e^{-((x-\mu)/\sigma)}]$$

where for the fitted model: x = log (concentration) of chloride (mg/L), y is the proportion of species affected, μ = 2.93 and σ = 0.29. The long-term SSD is shown in Figure 2 and summary statistics are presented in Table 6. The 5th percentile on the long-term SSD is 120 mg Cl^-/L which is within the range of the data (to which the model was fit). Therefore the 5th percentile and its fiducial limits (FL) (boundaries within which a parameter is considered to be located) are interpolations.

Two data points fall below the long-term SSD 5th percentile value of 120 mg Cl^-/L. These include the 24-hour EC_{10}s of 24 mg Cl^-/L (Bringolf 2010) and 42 mg Cl^-/L (Gillis 2009) for two species of mantle lure spawning freshwater mussels (glochidia lifestage), including *Lampsilis fasciola* (COSEWIC special concern) and *Epioblasma torulosa rangiana* (COSEWIC endangered), respectively. The CCME guideline derivation protocol (CCME 2007) provides the option of implementing the Protection Clause in situations where a data point for a species at risk, a species of commercial or recreational importance, or an ecologically important species falls below the 5th percentile (CWQG) value on the long-term SSD. In areas where the COSEWIC special concern mussel (*L. fasciola*) or the COSEWIC endangered mussel (*E. torulosa rangiana*) are present, the protection clause can

Table 5. Endpoints used in the SSD to determine the long-term CWQG for the chloride ion where freshwater mussels are present.

[a]Committee on the Status of Endangered Wildlife in Canada; Canadian occurrence in Ontario.
[b]Natality is "a measure of population increase under an actual specific environmental condition varying with the size and composition of the population and the physical environmental conditions" (Mackie 1978).

be implemented, resulting in a guideline value ranging from 24 to 42 mg Cl^-/L. In all other areas where non-endangered freshwater mussels are present, the long-term SSD 5th percentile value of 120 mg Cl^-/L should be used as the guideline value. As was discussed earlier, mussel toxicity data that were used for long-term CWQG derivation (as well as short-term benchmark concentration) commonly relied on exposures in reconstituted water. Therefore by design, CWQGs will likely be conservative values.

One long-term study that was not added to the long-term SSD dataset used road salt in place of NaCl salt, and is worth discussing here. The study involved exposing egg clutches of the spotted salamander (*Ambystoma maculatum*) to three chloride concentration treatments: 1 mg/L (chloride measured in vernal pools >200m from a highway), 145 mg/L (mean chloride measured in vernal pools within 200m of a highway), and 945 mg/L (maximum chloride measured in vernal pools within 200m of a highway) (Karraker and Gibbs 2011). Egg clutches were exposed to these chloride concentrations for a 9 day period, after which they were transferred to control water for another 9 day period and were weighed at day 3, 6, and 9 following transfer into clean water. The transfer into clean water was intended to mimic the dilution that occurs in vernal breeding pools following spring rainfall. Over the entire 18 day test period, clutches in the 1 mg/L treatment increased in mass by an average 25%, those in the 145 mg/L treatment lost an average mass of 2%, while clutches in the 945 mg/L treatment lost an average mass of 45%. Diluting rains may therefore aid in ameliorating the effects of moderate chloride concentrations in vernal breeding pools. However high chloride in breeding habitats may permanently disrupt the ability of egg clutches to osmoregulate or take up water. This could result in increasing risk of predation, freezing, malformations and other adverse effects to embryos of the spotted salamander (Karraker and Gibbs 2011). The CWQG of 120 mg Cl^-/L is expected to be protective of the early life stage of the spotted salamander.

Therefore, the long-term exposure CWQG for the protection of freshwater life is 120 mg Cl^-/L for the chloride ion.

Marine Water Quality Guideline: approximately 35,000 mg/L of which approximately 55% is chloride, which equates to 19,250 mg chloride/L. For this reason, brine discharges to marine environments were not evaluated.

Table 6. Long-term freshwater CWQG for the chloride ion resulting from the SSD Method.

	Concentration
SSD 5th percentile	**120 mg Cl^-/L**
SSD 5th percentile, 90% LFL (5%)	90 mg Cl-/L
SSD 5th percentile, 90% UFL (95%)	150 mg Cl^-/L

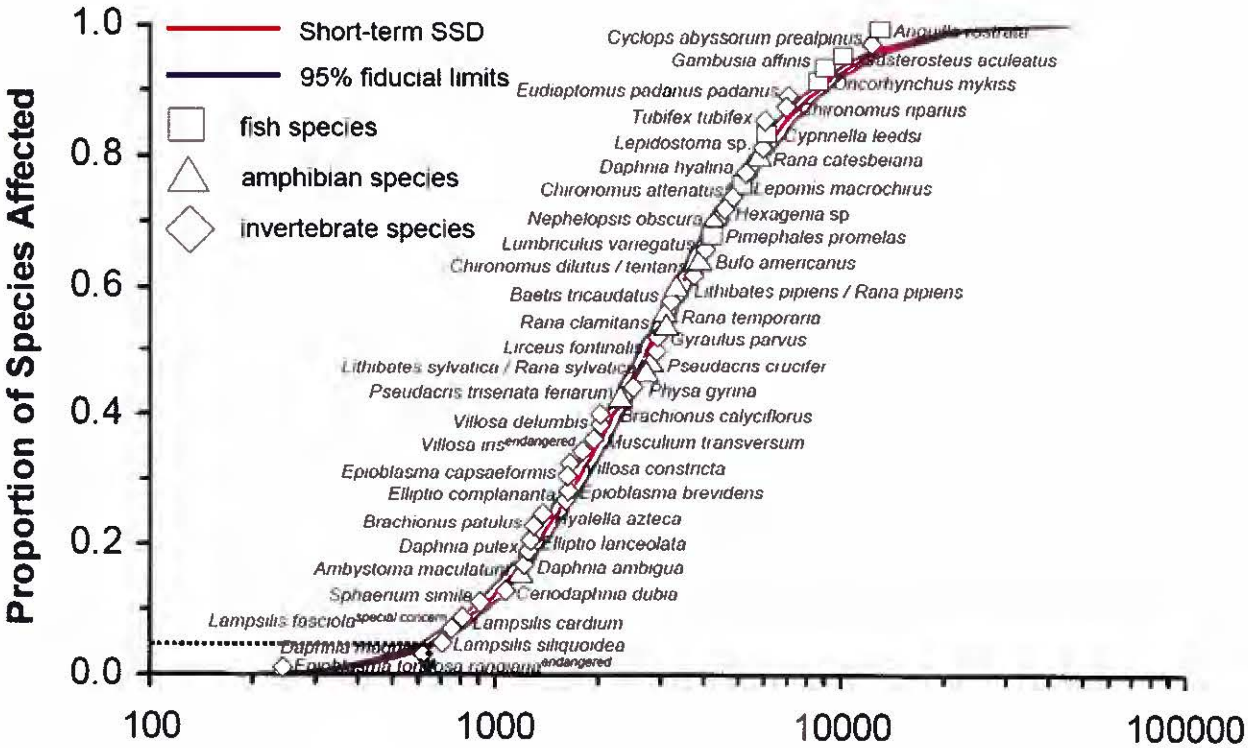
Guidance on the Use of Guidelines: These guidelines for the chloride ion are only intended to protect against direct toxic effects of chloride, based on studies using NaCl and $CaCl_2$ salts. The guideline should be used as a screening and management tool to ensure that chloride does not lead to the degradation of the aquatic environment. Further guidance on the application of these guidelines is provided in the scientific criteria document (CCME 2011).

The short-term benchmark concentration and long-term CWQG for chloride are set to provide protection for short- and long-term exposure periods, respectively. They are based on generic environmental fate and behaviour and toxicity data. The long-term water quality guideline is a conservative value below which all forms of aquatic life, during all life stages and in all Canadian aquatic systems, should be protected – with one exception. As noted earlier, the CWQG may not be protective of the early (glochidia) life-stage certain species of COSEWIC endangered and special concern freshwater mussels (discussion with provincial regulators should occur if there is a need to develop more protective site specific values). Because the guideline is not corrected for any toxicity modifying factors (e.g. hardness), it is a generic value that does not take into account any site-specific factors. Moreover, since the guideline is mostly based on toxicity tests using naïve (i.e., non-tolerant) laboratory organisms, the guideline may be over-protective for areas with a naturally-elevated concentration of chloride and associated adapted ecological community (CCME 2007). Thus, if an exceedence of the guideline is observed (due to anthropogenically-enriched water or because of elevated natural background concentrations), it does not necessarily suggest that toxic effects will be observed, but rather indicates the need to determine whether or not there is a potential for adverse environmental effects. In some situations, such as where an exceedence is observed, it may be necessary or advantageous to derive a site-specific guideline that takes into account local conditions (water chemistry, natural background concentration, genetically-adapted organisms, community structure) (CCME 2007). CCME has outlined several procedures to modify the national water quality guidelines to site-specific water quality guidelines or objectives to account for unique conditions and/or requirements at the site under investigation (CCME 1991; CCME 2003; Intrinsik 2010).

Fiducial limits (FLs) are reported here (Table 6) along with the 5th percentile or guideline value, and are similar to confidence intervals. FLs help assess the fit of the selected curve or model to the dataset. As the number of data points plotted on an SSD increases, the fit of FLs should be tighter. FLs can also be used to help interpret monitoring data, particularly if the guideline and method detection limit are close. Only the 5th percentile is used as the guideline.

In general, Canadian Water Quality Guidelines (CWQG) are numerical concentrations or narrative statements that are recommended as levels that should result in negligible risk of adverse effects to aquatic biota. As recommendations, the CWQGs are not legally enforceable limits, though they may form the scientific basis for legislation, regulation and/or management at the provincial, territorial, or municipal level. CWQGs may also be used as benchmarks or targets in the assessment and remediation of contaminated sites, as tools to evaluate the effectiveness of point-source controls, or as "alert levels" to identify potential risks.

CWQG values are calculated such that they protect the most sensitive life stage of the most sensitive aquatic life species over the long term. Hence, concentrations of a parameter that are less than the applicable CWQG are not expected to cause any adverse effect on aquatic life. Concentrations that exceed the CWQGs, however, do not necessarily imply that aquatic biota will be adversely affected, or that the water body is impaired; the concentration at which such effects occur may differ depending on site-specific conditions. Where the CWQGs are exceeded, professional advice should be sought in interpreting such results. As with other CWQGs, the guidelines for chloride are intended to be applied towards concentrations in ambient surface waters, rather than immediately adjacent to point sources such as municipal or industrial effluent outfalls. Various jurisdictions provide guidance on determining the limits of mixing zones when sampling downstream from a point source (see, for example, BC MELP 1986 and MEQ 1991), though Environment Canada and CCME do not necessarily endorse these methods.



Chloride (mg/L)

Figure 1. SSD of short-term L/EC$_{50}$ toxicity data for the chloride ion in freshwater derived by fitting the Normal model to the logarithm of acceptable toxicity data for 51 aquatic species versus Hazen plotting position (proportion of species affected). The arrow at the bottom of the graph denotes the 5th percentile and the corresponding short-term benchmark concentration value.

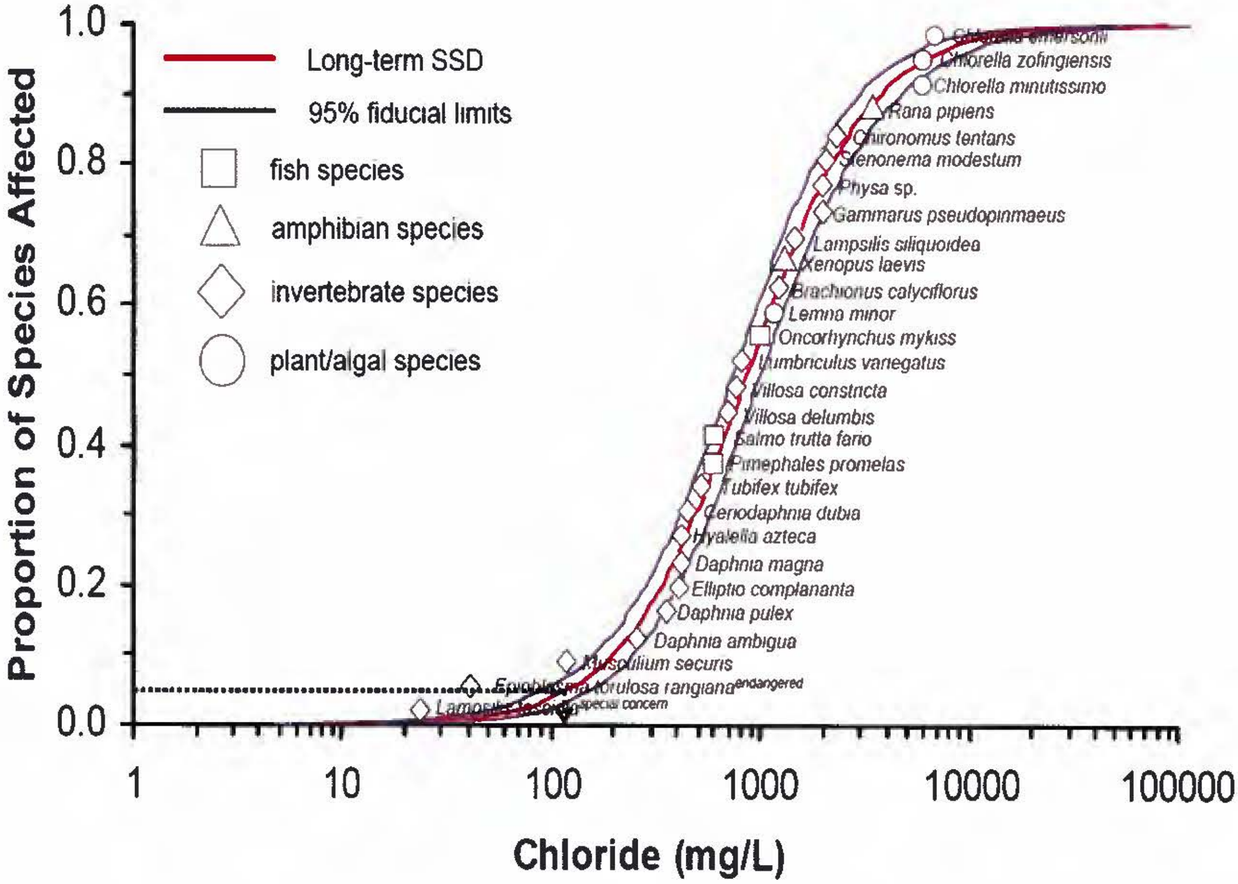


Figure 2. SSD of long-term no- and low-effect endpoint toxicity data for the chloride ion in freshwater (where mussels are present) derived by fitting the Logistic model to the logarithm of acceptable data for 28 aquatic species versus Hazen plotting position (proportion of species affected). The arrow at the bottom of the graph denotes the 5th percentile and the corresponding long-term Canadian Water Quality Guideline value.

APPENDIX M

ECOLOGICAL RESULTS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX M: ECOLOGICAL RESULTS

In the quantitative assessment the estimated intakes or media concentrations (EPCs) of constituents of potential concern (COPC) were compared to the toxicity reference values (TRVs) to derive a screening index (SI) value as follows:

$$SI = \frac{EPC \text{ or } Intake}{TRV}$$

An SI value of 1.0 is used for comparison when the receptor's entire exposure has been accounted for in the exposure assessment. This can include consideration of exposure from background if the receptor does not reside entirely on the site. For this assessment an SI value of 1.0 was used as the assessment point.

An SI value above the acceptable value (i.e., 1.0) does not necessarily indicate an effect but highlights combinations of receptors and COPC that require further consideration as there is a greater potential for an effect. A weight-of-evidence approach involving field observations and spatial considerations is used to determine whether there is the possibility of a population effect for those COPC with an SI value above 1.

M.1 Aquatic Environment

M.1.1 Aquatic Biota

Potential effects to aquatic biota (i.e., zooplankton, phytoplankton, benthic invertebrates, and fish) were evaluated using SSD curves, which are a statistical representation of available toxicity data for each COPC. Aquatic COPC evaluated in this way were antimony, arsenic, chloride, and sulphate. Sulphate toxicity has been shown to be hardness dependent and so expected hardness of each evaluated area was used to ensure the correct SSD curve was employed.

Conditions were evaluated in this way for current, immediately post-remediation (2030), and 100 years in the future (2120) in the modelled segments of lower Baker Creek and Back Bay.

M.1.2 Fish

In addition to development and use of SSD curves, an additional line of evidence was used for evaluating potential effects to fish. Levels of COPC in fish were compared to fish tissue benchmarks from literature sources. The values from literature are presented in Appendix L and are compared to measured (current) and predicted (future) Baker Creek fish levels. This comparison is shown in the tables below.

Table M.1 Comparison of measured arctic grayling concentrations to available benchmarks – current – Baker Creek

COPC	Fish Tissue Benchmark [a]		Measured Whole Body Arctic Grayling Summary Statistics							
	NOEC	LOEC	N	N<MDL	Min	Max	Mean	St Dev	Geo Mean	95th Percentile
	mg/kg ww									
Antimony	5	9	4	0	0.50	0.62	0.55	0.05	0.55	0.61
Arsenic	1.5	2	4	0	7.5	16	12	3.6	12	16

M.2 Terrestrial Environment

M.2.1 Terrestrial Vegetation

To evaluate potential effects on terrestrial vegetation, predicted foliage concentrations were compared to phytotoxic concentrations presented in literature. The values from literature are presented in Appendix L in mg/kg on a dry weight basis (dw) and were converted to mg/kg on a wet weight basis (ww) for comparison to measured (current) and predicted (future) foliage levels using moisture content for foliage samples collected on the Giant Mine.

Table M.9 Comparison of measured foliage concentrations to phytotoxic levels – current – Trapper Lake North

COPC	Phytotoxic Range	Measured Foliage Summary Statistics								
		N	N<MDL	Min	Max	Mean	St Dev	Geo Mean	95th Percentile	95% UCLM
	mg/kg ww									
Antimony	65 [a]	21	0	0.01	0.77	0.15	0.16	0.10	0.32	0.22
Arsenic	1.3-11 [a]	21	0	0.43	5.1	1.4	1.0	1.1	2.7	1.8
Copper	8.6-43 [a]	21	0	0.74	2.5	1.4	0.48	1.3	2.4	1.6
Manganese	172-430 [a]	21	0	23	707	144	206	76	702	340
Zinc	43-645 [a]	21	0	2.7	7.3	4.7	1.2	4.6	7.2	5.2

Note: [a] converted from dw to ww using a Giant Mine sample average moisture content of 57 % moisture.

Table M.10 Comparison of measured foliage concentrations to phytotoxic levels – current – West of Baker Creek

COPC	Phytotoxic Range	Measured Foliage Summary Statistics								
		N	N<MDL	Min	Max	Mean	St Dev	Geo Mean	95th Percentile	95 UCLM
	mg/kg ww

[b] predicted concentrations for shrew/mouse

M.3 Sample Calculations

A sample calculation of the food chain model was presented in Appendix K. This included the exposure assessment as well as the estimation of the SI.

APPENDIX N

ECOLOGICAL SENSITIVITY ANALYSIS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX N: ECOLOGICAL SENSITIVITY ANALYSIS

Uncertainty is inherent in risk assessment. For this reason, a sensitivity analysis was undertaken to examine the potential effects of some key areas of uncertainty in the ecological risk assessment (ERA) for the Giant Mine site. These are the factors that were studied:

A. Water/sediment model predictions
B. Use of bioavailability and arsenobetaine assumptions
C. Basis for derivation of toxicity reference values (TRVs)
D. Soil remediation assumptions
E. Basis for terrestrial insect concentrations

N.1 Water/Sediment Model Predictions (Case A)

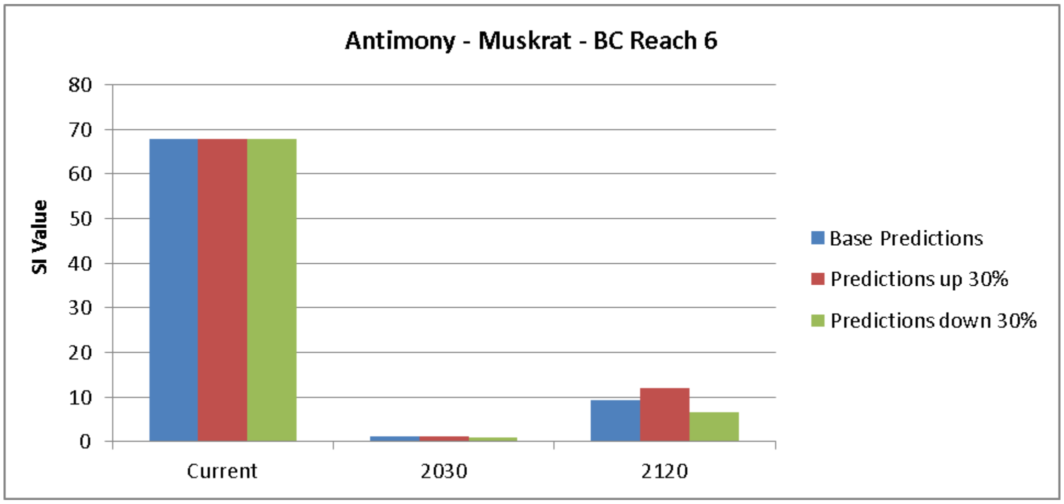
For this sensitivity case, future water and sediment concentrations were varied from the modelled values by ± 30% in Baker Creek and ± 10% in Back Bay. This case examines the potential implication of uncertainty in the modelling including differences to loading estimates, variations in precipitation or flow, biogeochemical influences on sediment, uncertainty with partitioning to sediment, and any improvement in runoff from the Giant Mine over time.

Future climate change may include warmer temperatures, leading to greater precipitation, greater evaporation, changes to the balance between snowfall and rainfall, and changes to the timing of freeze-up and spring freshet. The nature of the Baker Creek watershed means that increased precipitation may be offset to some extent by increased evaporation. Peak flows may also be affected by changes to the seasonal distributions of rainfall, snowfall and snow melt. The range of available climate models is broad, and projections would vary greatly depending on the choice of model and climate change scenario. Furthermore, the models generally project much lower changes in the early time period (e.g., 2040 to 2070) than later periods (e.g., 2070 to 2100). The uncertainty associated with climate model projections, as well as the small changes generally projected in future decades compared to those in the longer term, mean that an historically-based flow regime characterization should be sufficient through mid-century (Golder 2017).

This sensitivity case also addresses potential changes in the future due to climate change. In general, the long-term meteorological data set for Yellowknife shows a trend toward milder temperatures and more precipitation (INAC/GNWT 2010) which can change the balance between snowfall and rainfall and increase evaporation. However, it is difficult to make definitive conclusions on the changes expected over the timeframe of the assessment. In the Giant Mine Developer's Assessment Report (DAR; INAC/GNWT 2010) it was reported that the Canadian Climate Change Scenarios Network (CCCSN) assessment indicated that precipitation may increase by up to 15% over the next 50 years. Therefore a 30% change in the flow of Baker Creek over the 100 year period was selected for the sensitivity case. It is noted thought that a recent assessment by Golder (2017) found that with the uncertainty associated with climate model projections, as well as the small changes generally projected in future decades compared to those in the longer term, mean that an historically-based flow regime characterization should be sufficient through mid-century. As Great Slave Lake is such a large waterbody it is expected that the change would not be as pronounced in this waterbody. There are numerous and varied implications of increased precipitation. An increase in flow would provide additional water for dilution but also has the potential to increase the load from surface runoff. Higher temperatures may increase plankton growth and therefore additional removal of contaminants into sediment but high flow, particularly sporadic flow associated with more extreme precipitation events, can scour and mobilize depositional sediment. Increased water temperatures may also have an impact on chemical reaction kinetics. The future impact of climate change on the aquatic environment is uncertain; therefore, the potential change in water and sediment quality was examined from a potential increase and decrease in the estimated concentrations.

As this change is most relevant to the aquatic environment example, SI values are shown below for muskrat in the Lower Reaches of Baker Creek (Figure N.1) and mink in Back Bay (Figure N.2). As can be seen, increases or decreases in the future predicted water and sediment quality are not expected to affect the estimated screening index (SI) values dramatically or change the overall conclusions of the ERA.

Figure N.1 Sensitivity case A – muskrat – Baker Creek Reach 6



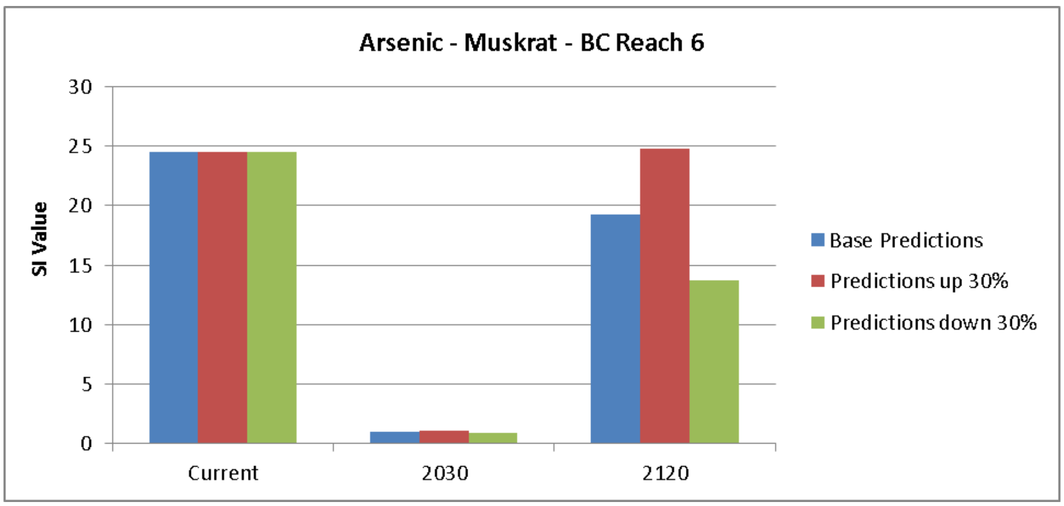


Figure N.2 Sensitivity case A – mink – Back Bay

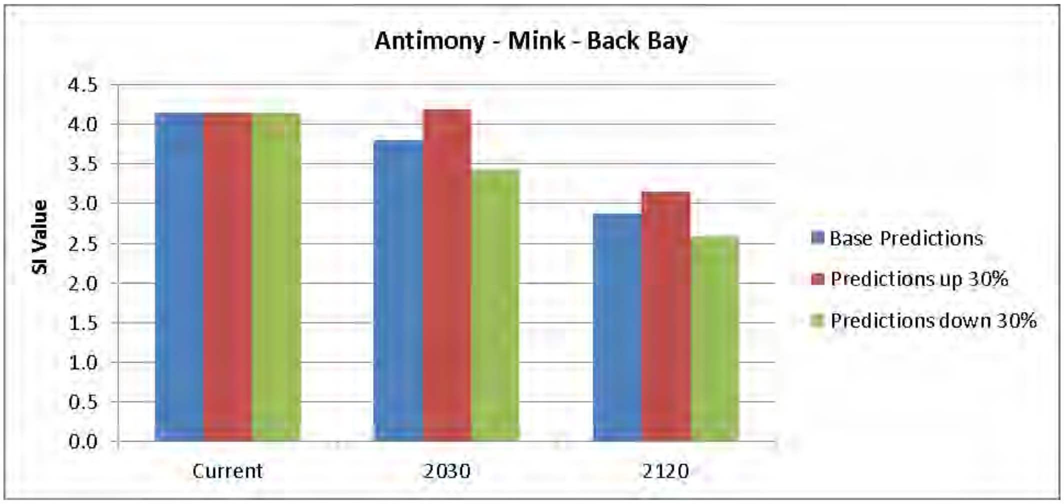

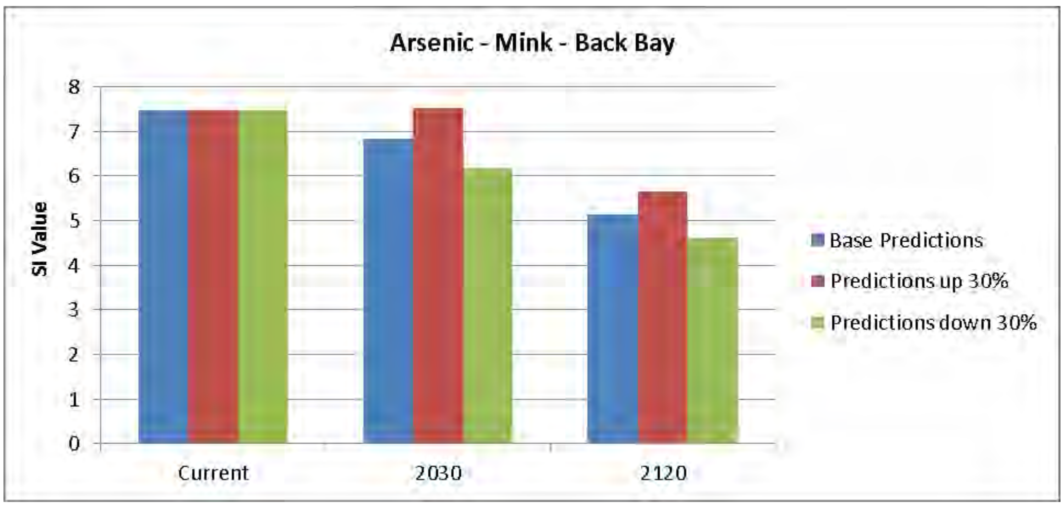

N.2 Bioavailability and Arsenobetaine Assumptions (Case B)

N.2.1 B1 – Arsenic Bioavailability and Arsenobetaine Assumptions

This sensitivity analysis looked at the uncertainty regarding the understanding of arsenic bioavailability and arsenobetaine content of fish. For this analysis, the arsenic bioavailability was assumed to be 100% with no non-toxic (arsenobetaine) component; this is the most conservative assumption that could be made regarding these factors.

Since bioavailability and arsenobetaine assumptions were only made for arsenic in the ERA, only arsenic is presented below. Examples are provided for muskrat in Baker Creek Reach 6 (Figure N.3), mink in Back Bay (Figure N.4), swallow in Lower Baker Creek (Figure N.5), fox on the entire site (Figure N.6), and lynx on the entire site (Figure N.7). As can be seen, while this assumption has a small effect on results for the smaller receptors, this influence is increased for the larger animals (i.e., fox and lynx) as the effect of the assumption is compounded moving up the food chain. Ignoring available bioavailability information has the potential to change the overall result for the larger receptors, however, the assumption of 100% bioavailability and 100% toxic is overly conservative and not realistic.

Figure N.3 Sensitivity case B1 – muskrat – Baker Creek Reach 6

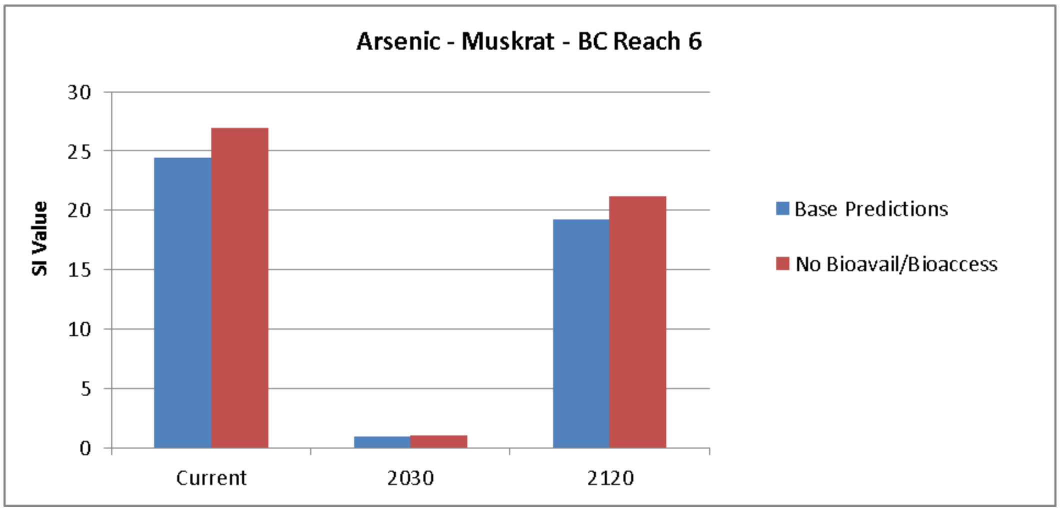

Figure N.4 Sensitivity case B1 – mink – Back Bay

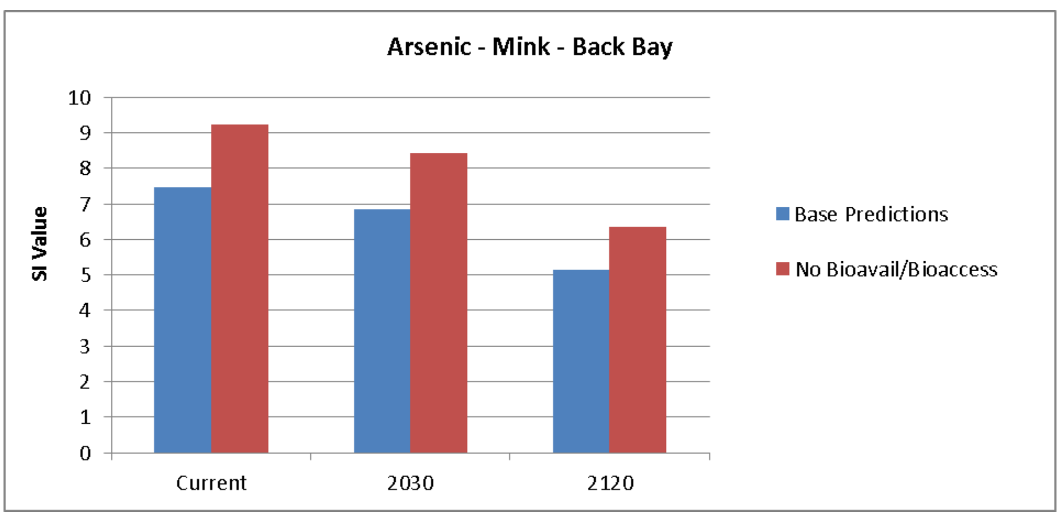

Figure N.5 Sensitivity case B1 – swallow – lower Baker Creek

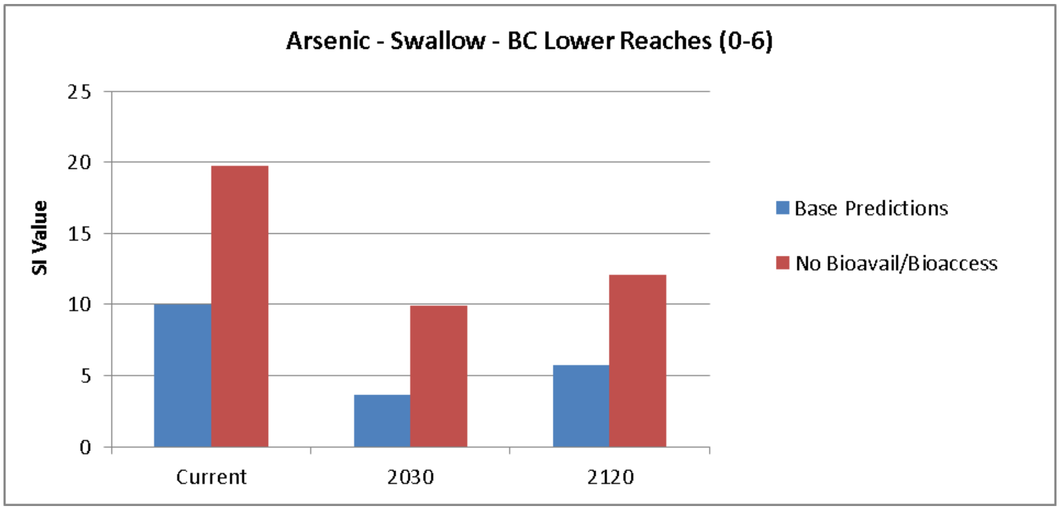

Figure N.6 Sensitivity case B1 – fox – Entire Site

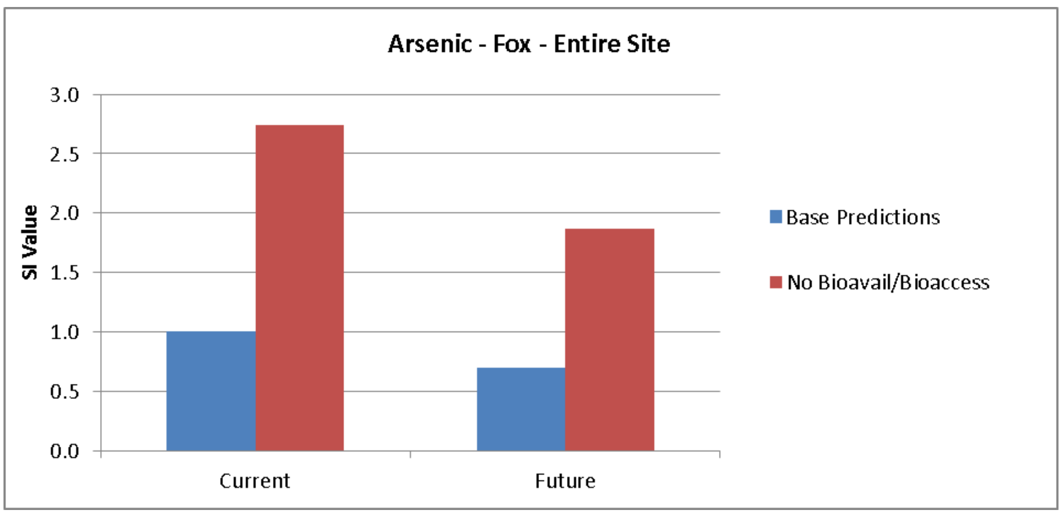

Figure N.7 Sensitivity case B1 – lynx – Entire Site

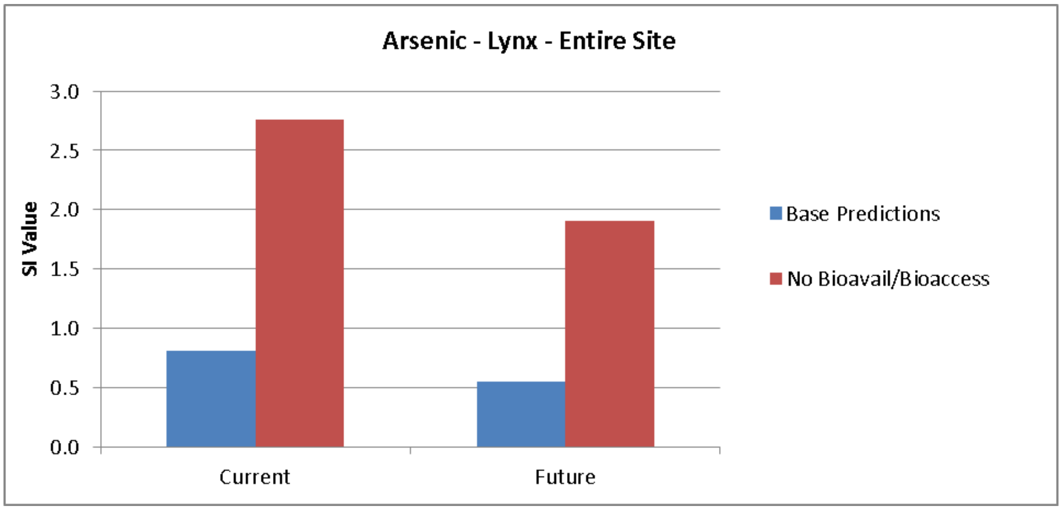

N.2.2 B2 - Antimony Soil Bioavailability

Bioavailability data were only available for arsenic, for this reason bioavailability assumptions within the ERA were only made for arsenic and the bioavailability of all other COPC were assumed to be 100%. This sensitivity case looks at the implications of applying bioavailability assumptions to antimony in soil. A study completed by Li et al. (2014), which looked at the antimony and arsenic bioaccessibility in highly polluted soils associated with a mine, found that the bioaccessibility values for antimony were in most cases less than 30%. Therefore, for this sensitivity case, the antimony soil bioaccessibility was assumed to be 30%. Examples are shown below for shrew in West of Baker Creek (Figure N.8), bat in East of Baker Creek (Figure N.9), and a lynx on the entire site (Figure N.10). As can be seen, taking into account the bioavailability/bioaccessibility of COPC other than arsenic has the potential to substantially reduce predicted SI values for evaluated receptors. However, as illustrated in the examples provided, SI values for most receptors (both current and future) remain above the benchmark of 1.

Figure N.8 Sensitivity case B2 – shrew – West of Baker Creek

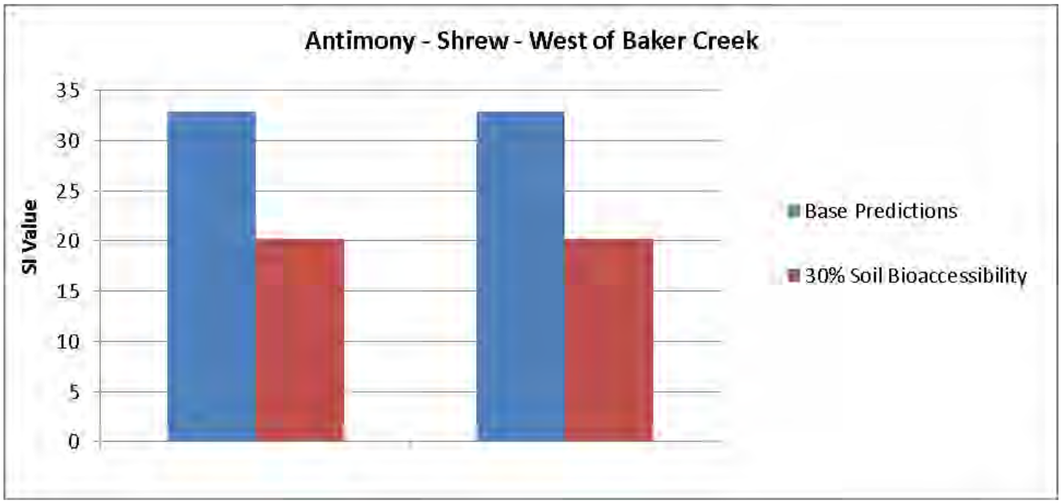

Figure N.9 Sensitivity case B2 – bat – East of Baker Creek

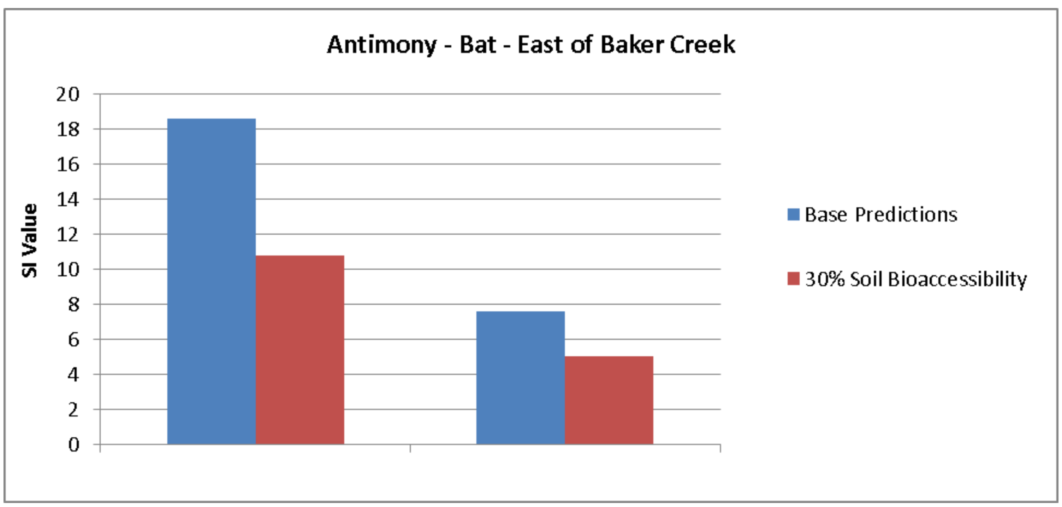

Figure N.10 Sensitivity case B2 – lynx – Entire Site

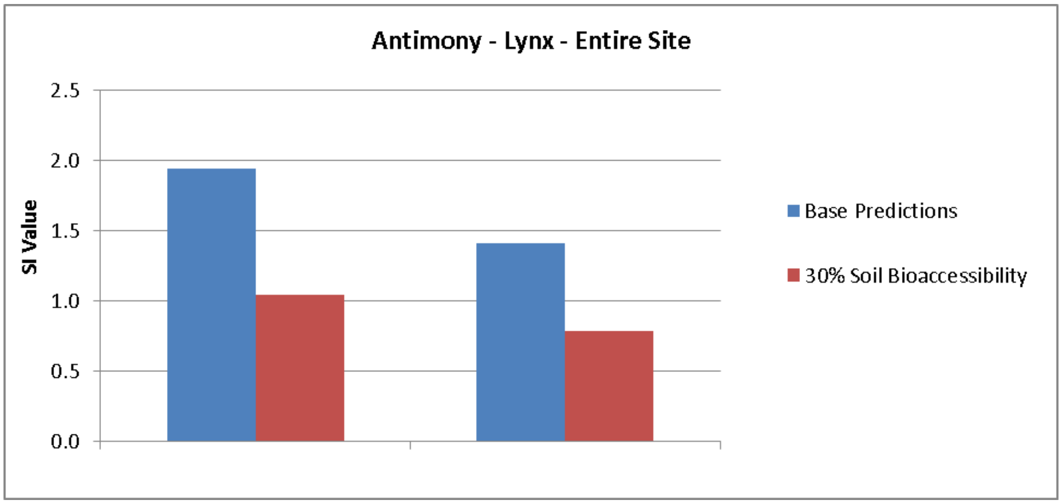

N.3 Toxicity Reference Values (Case C)

This sensitivity case examined the use of lowest observable adverse effect levels (LOAELs) as toxicity reference values (TRVs) instead of the no observed adverse effect levels (NOAELs) adopted for the ERA. The use of LOAELs is less conservative than using NOAELs and is an accepted approach in many jurisdictions.

The NOAEL-based TRVs (used in the ERA) and LOAEL-based TRVs (used in this sensitivity analysis) are presented below in Table N.1. The shading in the table indicates that there were no SI values predicted to be above the benchmark of 1 for any receptors using the NOAEL benchmarks and so these combinations of receptors and COPC are not discussed further. Examples for this sensitivity case include swallow in East of Baker Creek (Figure N.11), shrew in West of Baker Creek (Figure N.12), and fox on the entire site (Figure N.13). As can be seen, the use of LOAELs over NOAELs can change results substantially in those cases where the two TRVs are very different. While this changes the outcome for a number of receptors, there are some future SI values that are expected to remain above 1; this includes some locations for antimony (shrew), arsenic (ptarmigan, swallow, shrew), and manganese (mouse, bat, swallow, shrew) so is unlikely to change the overall conclusions of the ERA.

Table N.1 Summary of NOAEL and LOAEL based TRVs

COPC	Mammals				Birds			
	NOAEL TRV (mg/kg-d)	Source	LOAEL TRV (mg/kg-d)	Comment	NOAEL TRV (mg/kg-d)	Source	LOAEL TRV (mg/kg-d)	Comment
Antimony	0.059	Eco-SSL (U.S. EPA 2005a)	1.14	Geometric mean of three LOAELs [a]	-	-	-	-
Arsenic	1.04	Eco-SSL (U.S. EPA 2005b)	5.7	Geometric mean of the LOAELs for growth, reproduction and survival [a]	4.4	CEAEQ (2012)	4.5	Geometric mean of the LOAELs for growth, reproduction and survival [a]
Copper	5.6	Eco-SSL (U.S. EPA 2007a)	38	Geometric mean of the NOAELs for growth, reproduction and survival [a]	4.5	CEAEQ (2012)	37	Geometric mean of the LOAELs for growth, reproduction and survival [a]
Manganese	51.5	Eco-SSL (U.S. EPA 2007b)	146	Geometric mean for the LOAELs for growth and reproduction [a]	179	Eco-SSL (U.S. EPA 2007b)	348	Lowest bounded LOAEL for growth [a]
Zinc	75.4	Eco-SSL (U.S. EPA 2007c)	290	Geometric mean of the LOAELs for growth, reproduction and survival [a]	66.1	Eco-SSL (U.S. EPA 2007c)	190	Geometric mean of the LOAELs for growth, reproduction and survival [a]

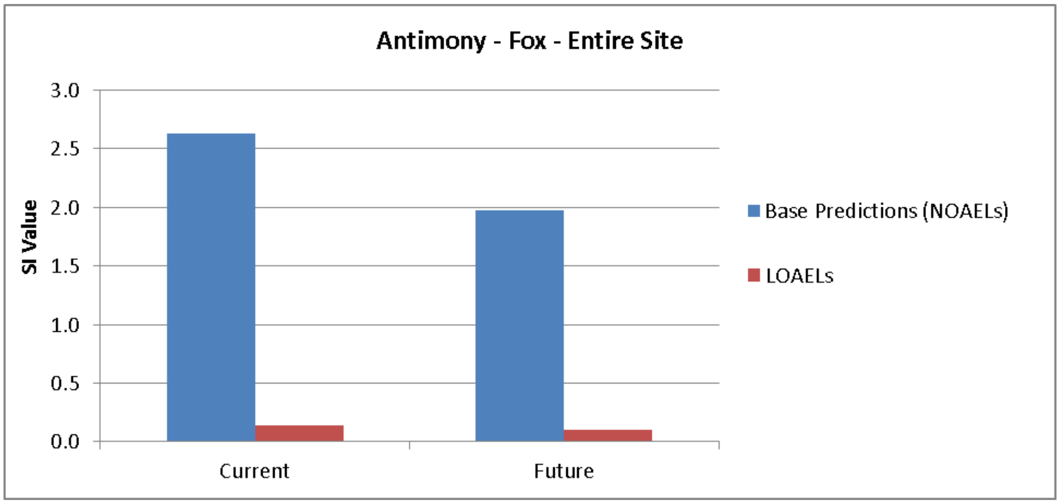
Figure N.13 Sensitivity case C – fox – Entire Site

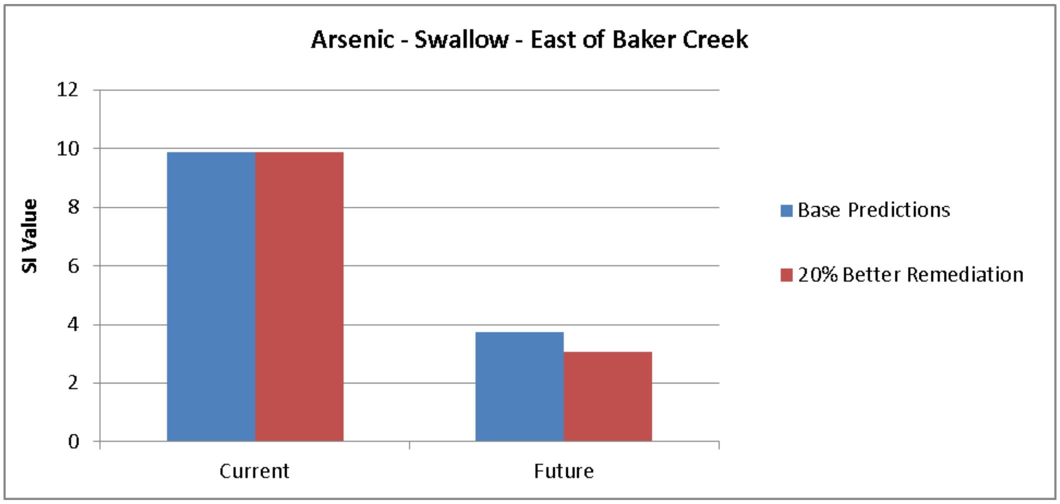


N.4 Soil Remediation (Case D)

Sensitivity case D looked at the sensitivity of results to assumed post-remediation soil concentrations at the Giant Mine. This analysis was done to capture uncertainty regarding the final remediation of the site and to see if there would be substantive changes to the ERA results if plans change and more of the site is addressed. This study investigated the potential effect if the soil remediation was able to achieve 20% lower soil concentrations than currently predicted.

Example results are shown below for swallow in East of Baker Creek (Figure N.14), Shrew in East of Baker Creek (Figure N.15), and fox on the entire site (Figure N.16). As can be seen, 20% improvement in future soil levels is predicted to make only a slight difference to calculated SI values and so the uncertainty in soil remediation planning and execution is unlikely to change the overall outcomes of the ERA.

Figure N.14 Sensitivity case D – swallow – East of Baker Creek



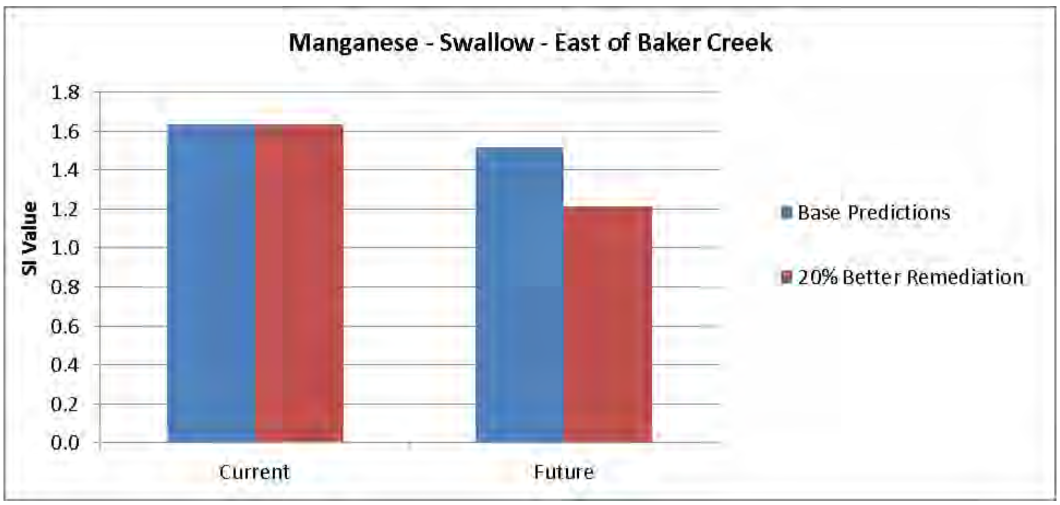


Figure N.15 Sensitivity case D – shrew – East of Baker Creek

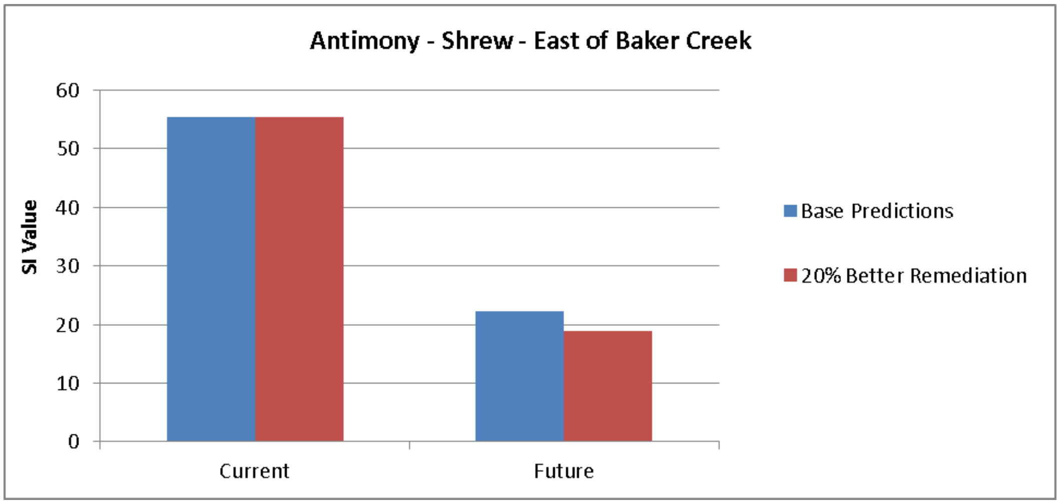

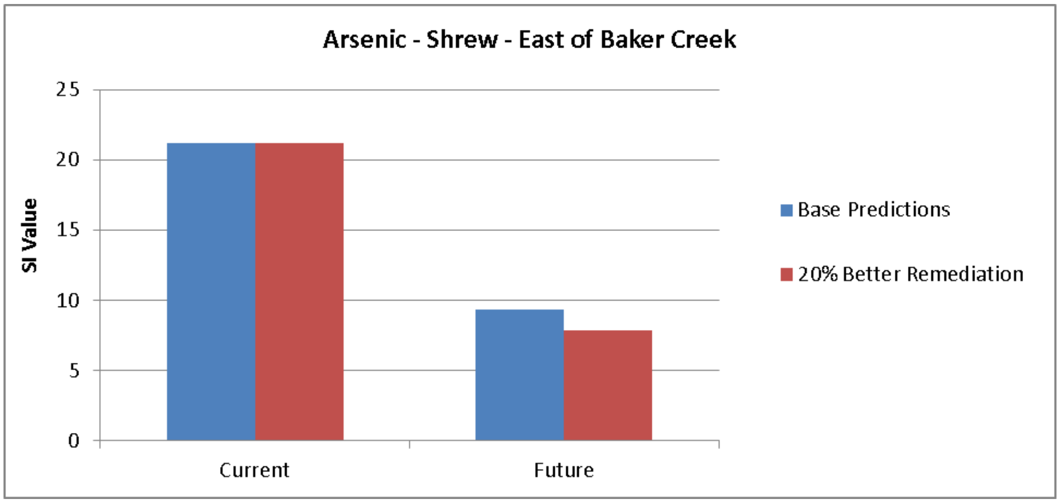

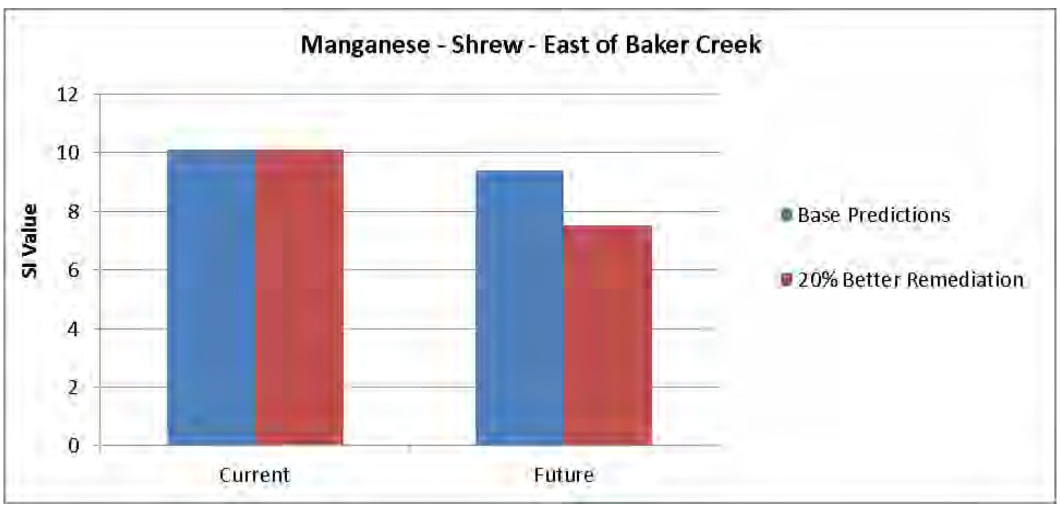

Figure N.16 Sensitivity case D – fox – Entire Site

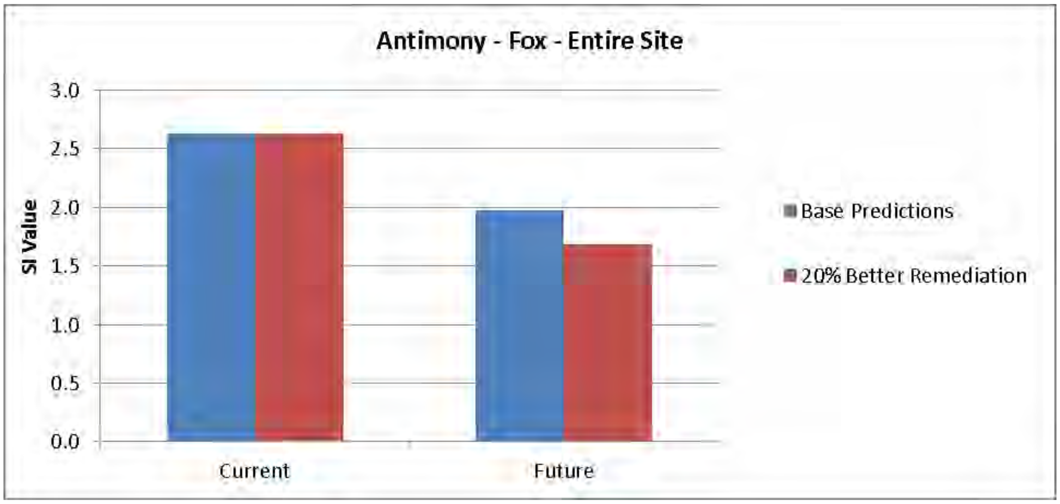

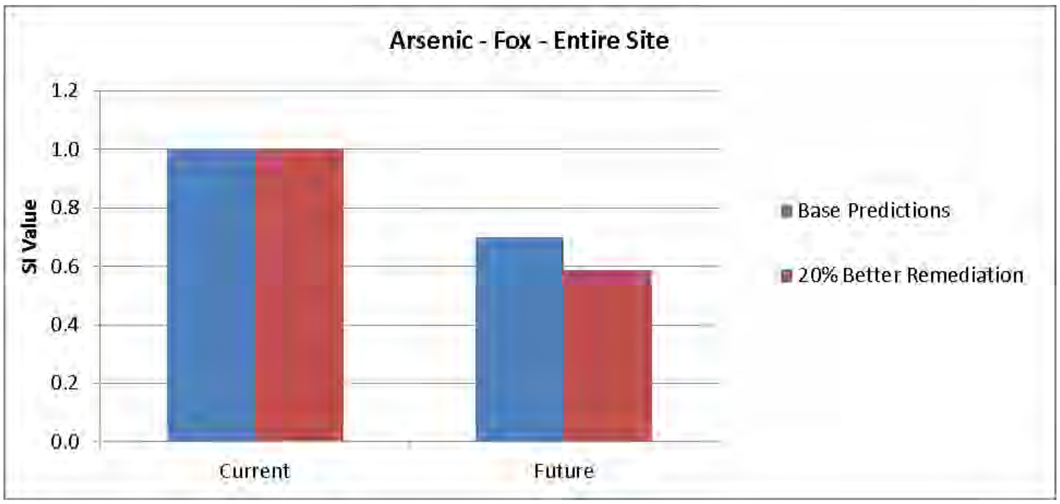

N.5 Terrestrial Insects (Case E)

Mammals and birds that consume insects were identified as a potential concern in the ERA. The concentration of COPC within terrestrial insects is a large uncertainty in this ERA as there are no data available for insects. Within the ERA, the terrestrial insects are set equal to concentrations within foliage.

Some studies suggest that insects may have higher concentrations than vegetation (e.g., Hernout et al. (2013) suggest copper and zinc levels in insects may be comparable to soil). The levels of essential elements such as copper and zinc may not be a direct reflection of the soil concentration however, due to active regulation of these elements by insects.

For arsenic it is possible that insects are less than vegetation. In this sensitivity case, a slightly less conservative approach was adopted and it is assumed that the insect concentrations are equal to the bioavailable fraction of arsenic in the foliage and not the entire concentration, as was assumed in the ERA calculations.

Examples are shown below for bat in East of Baker Creek (Figure N.17), shrew in South of Baker Creek (Figure N.18), and fox on the entire site (Figure N.19). As can be seen, there is a moderate difference between SI values for the two cases for the smaller mammals who consume terrestrial insects as a large portion of their diet; a much smaller difference is not seen for larger animals that consume a wider range of mammals and birds as their diet. Similar to other sensitivity cases, while this additional assumption does improve SI values for some receptors, SI values for most receptors remain above the benchmark of 1.

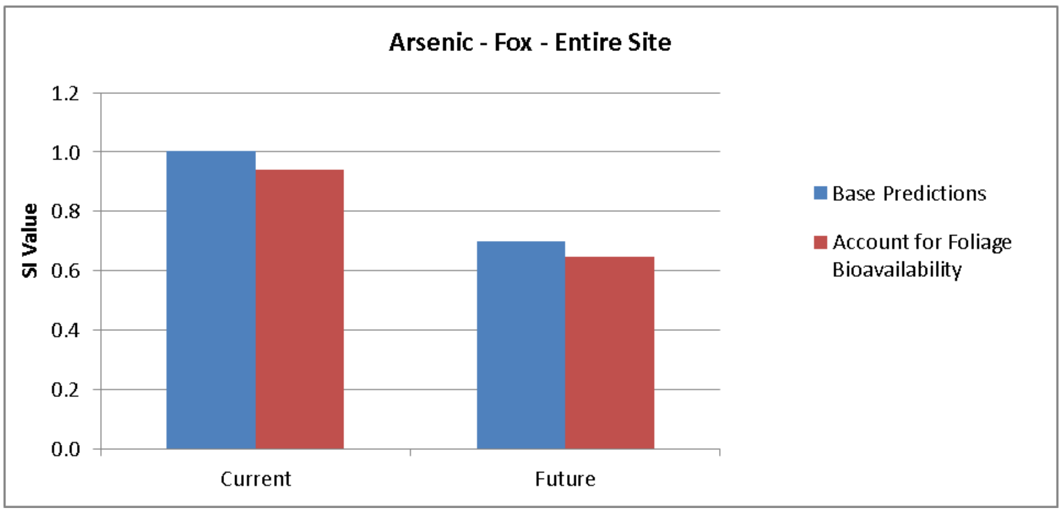
Figure N.19 Sensitivity case E – fox – Entire Site



N.6 Summary

A number of factors were investigated to evaluate the potential for uncertainty to change the overall outcomes of the ERA.

It was seen that the conclusions of the ERA are fairly insensitive to uncertainty in surface water/sediment modelling (case A) and to assumptions regarding the soil remediation (case D).

The results for larger receptors were seen to be sensitive to arsenic accessibility/toxicity assumptions (case B-1), however, the test assumptions of 100% bioavailability and 100% toxicity are overly conservative and, as shown by the available data, not realistic.

Both reducing the antimony soil bioavailability to a number which is likely more realistic (case B-2) and changing the basis for terrestrial insect concentrations (case E) resulted in reduced SI values for some receptors; however, additional site data on bioavailability in COPC other than arsenic and insect concentrations would be needed prior to implementing more realistic assumptions such as these within the ERA.

The use of less conservative TRVs (case C) could potentially have a substantial impact on the calculated SI values. Despite this, however, there are still many receptors with SI values above 1, indicating a potential for adverse effects. In addition, this approach is not appropriate for use with species at risk, such as the little brown bat and barn swallow.

In conclusion, while uncertainty in some factors may change predicted SI values for evaluated receptors, in every sensitivity case SI values for some receptors remained well above the benchmark of 1. For this reason uncertainty related to the examined factors is not expected to change the overall findings of the ERA.

APPENDIX O

DATABASE OF AVAILABLE MONITORING DATA

TABLE OF CONTENTS

APPENDIX O: DATABASE OF AVAILABLE MONITORING DATA

The complete database of information that was relied upon in the assessment is provided in two electronic files – one that summarizes the available monitoring data from the aquatic environment and one that summarizes the available monitoring data from the terrestrial environment.

The electronic files can be requested from:

Ms. Natalie Plato
Deputy Director
Indigenous and Northern Affairs Canada, Giant Mine Project

APPENDIX P

ADDITIONAL ANALYSES

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

APPENDIX P: ADDITIONAL ANALYSES

This Appendix provides an evaluation of additional voluntary samples and soil samples that became available after the submission of the draft Giant Mine Human Health and Ecological Risk Assessment (HHERA) in October 2017.

Additional soil samples were obtained from the GNWT Open File program and were used to supplement the soil database to characterize locations such as Ingraham Trail and Dettah where only a few samples were available. Additional voluntary samples for rabbits, berries, medicinal plants (including rat root), mushrooms and a few other samples were also collected from a 2017 country foods study and submitted for analysis to supplement the database of country foods consumed by the members of the different communities.

This appendix provides a comparison of how these additional new samples affect the exposure point concentrations (EPC) that were used in the main document and provides analyses for mushrooms and medicinal plants. As well, additional scenarios that were requested as part of the stakeholder consultation on the draft HHRA are presented in this Appendix.

P.1 Soil Investigation

After the draft HHERA was completed, additional soil data became available from the GNWT Open File program (Jamieson et al. 2017). This additional dataset was examined to see if any data could be incorporated into the HHERA for areas which are less fully characterized (i.e., Dettah and Ingraham Trail). The soil sample locations are shown in Figure P.1 for Dettah and Figure P.2 for Ingraham Trail. The additional samples obtained through the GNWT Open File program are presented in blue and the locations of the samples used in the main document of the HHERA are presented in purple. Note that the information presented is only for antimony and arsenic as no manganese data was supplied with the GNWT Open File dataset.

P.1.1 Dettah

Additional soil samples were available from the GNWT Open File program (Jamieson et al. 2017) for antimony and arsenic to supplement the soil samples originally used in the Draft HHERA. A map presenting the new sample locations is included in Figure P.1 and a summary of the data including the original dataset is presented in Table P.1. The addition of the GNWT data to the original dataset results in an adequate sample size to calculate 95% UCLMs to represent soils within Dettah (i.e., a sample size of 10).

Figure P.1 GNWT Open File Dettah sample locations

Note: Blue squares represent additional samples from GNWT Open File while purple squares represent those used in the main HHERA.

Table P.1 Summary of concentrations of COPC in the soils in Dettah

COPC	N	N<MDL	Soil Concentration (mg/kg)						
			Min	Max	Average	Standard Deviation	95th Percentile	GeoMean	95% UCLM
Antimony	10	1	0.2	6.2	2	2	6	1	3.4
Arsenic	11	0	7.2	144	39	46	130	24	69

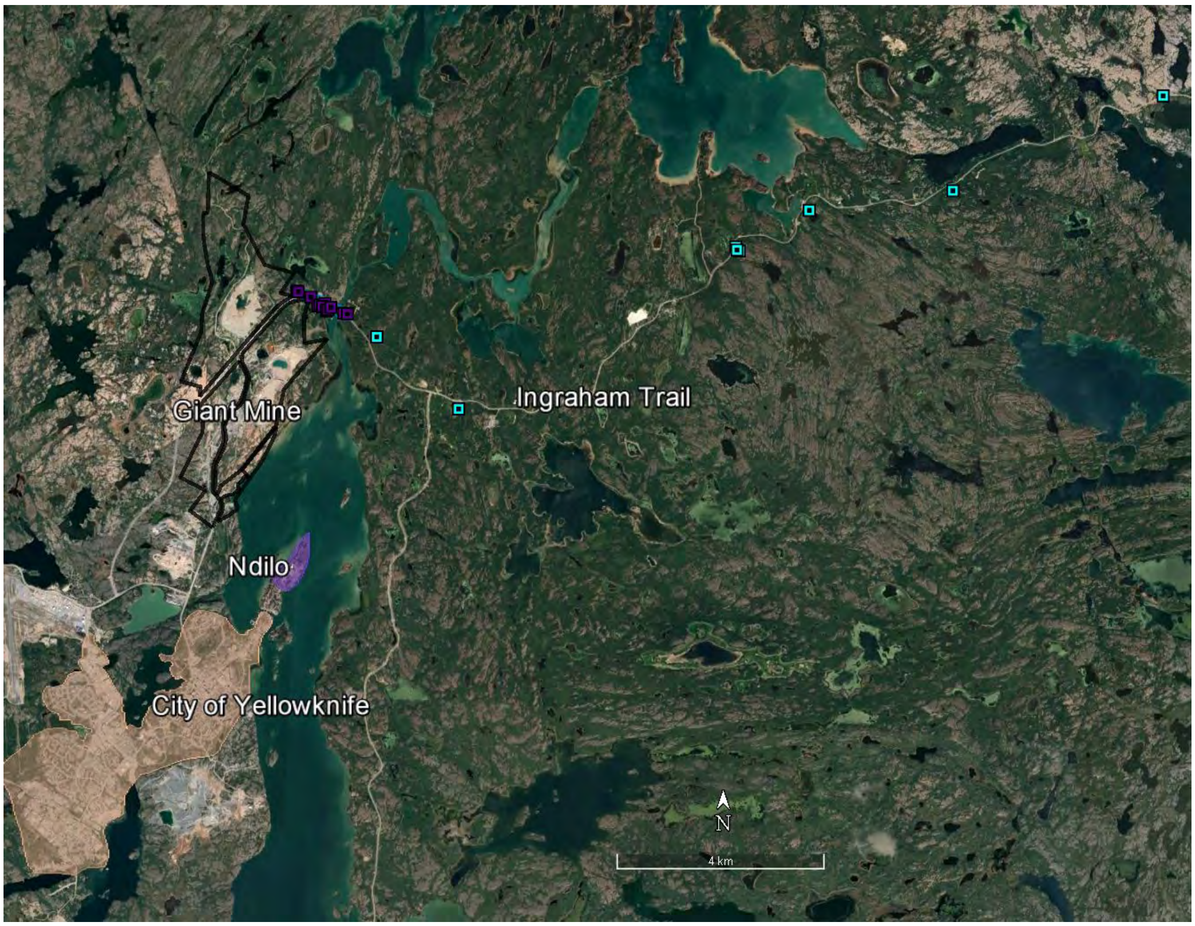
Note: Only antimony and arsenic are presented because only data for these COPC were available from the GNWT Open File program.

P.1.2 Ingraham Trail

Additional soil samples were available from the GNWT Open File program (Jamieson et al. 2017) to supplement the 12 soil samples originally used in the main document of the

HHERA. A map presenting the new sample locations is included in Figure P.2 and a summary of the data including the original data is presented in Table P.2. The addition of the GNWT data to the original datasets results in an adequate sample size to calculate 95% UCLMs to represent soils within Ingraham Trail (i.e., greater than a sample size of 10).

Figure P.2 GNWT Open File Ingraham Trail sample locations



Note: Blue squares represent additional samples from GNWT Open File while purple squares represent those used in the main HHERA.

Table P.2 Summary of concentrations of COPC in the soils in Ingraham Trail

COPC	N	N<MDL	Soil Concentration (mg/kg)						
			Min	Max	Average	Standard Deviation	95th Percentile	GeoMean	95% UCLM
Antimony	24	2	0.4	69	5.5	14	13	2	18
Arsenic	28	0	3.6	127	30	25	62	22	38

Note: Only antimony and arsenic are presented because only data for these COPC were available from the GNWT Open File program.

P.1.3 Summary

In order to determine the effect of the new data, a comparison was undertaken between the EPCs in Dettah and Ingraham Trail used in the main report and the updated EPCs discussed above which include the GNWT Open File data (see Table P.3).

Table P.3 Comparison of Dettah and Ingraham Trail soil EPCs with and without GNWT Open File data

COPC	Original EPC (mg/kg)	N	Derivation of Original EPC	Revised EPC (mg/kg)	N	Derivation of Revised EPC
Dettah						
Antimony	6.2	8	Maximum	3.4	10	BCA Bootstrap 95% UCLM
Arsenic	76	9	BCA Bootstrap 95% UCLM	69	11	BCA Bootstrap 95% UCLM
Ingraham Trail						
Antimony	38	12	95th percentile	18	24	Recommended 95% UCLM - ProUCL
Arsenic	96	12	95th percentile – chosen as higher than 95%UCLM	38	28	Recommended 95% UCLM - ProUCL

The revised EPCs for antimony and arsenic from Dettah and Ingraham Trail are represented by the 95% UCLM as there were an adequate number of samples to derive this statistic. As seen from Table P.3, the revised EPCs are lower than the original EPCs that were used in the HHRA. Given that the original EPCs were higher, the evaluation of soils from Dettah and Ingraham Trail presented in the main report of the HHRA are conservative and additional calculations are not warranted.

P.2 Voluntary Sampling Program

There were 74 additional samples collected in the spring and summer of 2017 and submitted for analysis in support of the HHRA. Additional samples included mushrooms, medicinal plants including rat root, additional hare and muskrat samples, and berries. Table P.4 provides a summary of the number of samples that were collected. In addition birch bark and fern leaves and crowberry samples were brewed into teas and both the ingredients and tea samples were sent for analysis. Maps of the locations of the additional samples are presented in Figure P.3 to Figure P.6. A list of the samples with the chemical analyses is provided in ATTACHMENT P.1. As seen from the figures, the majority of the additional samples were from within 10 km from the Giant Mine.

Table P.4 Summary of additional samples collected in spring and summer of 2017

Food Type	Species	Number of Samples
Small Mammals	Rabbit / muskrat	6 (rabbit) 2 (muskrat)
Plants and Berries	Raspberry / cloud berry / juniper berries / black currant / cranberry / crowberry / rose hips	15
Mushrooms	Various	38
Medicinal plants	Labrador tea / spruce gum / birch bark / rat root / tamarak bark / fern leaves	13
Total Number of Samples = 74		

Figure P.3 Additional voluntary samples from within 10 km of the Giant Mine

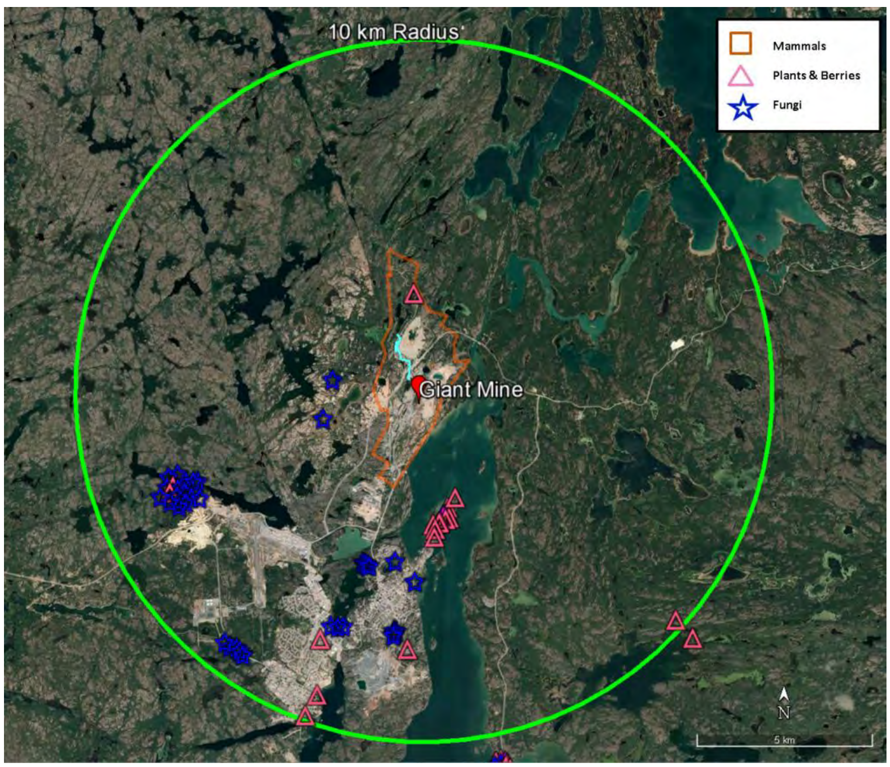


Figure P.4 Additional voluntary samples from within 25 km of the Giant Mine

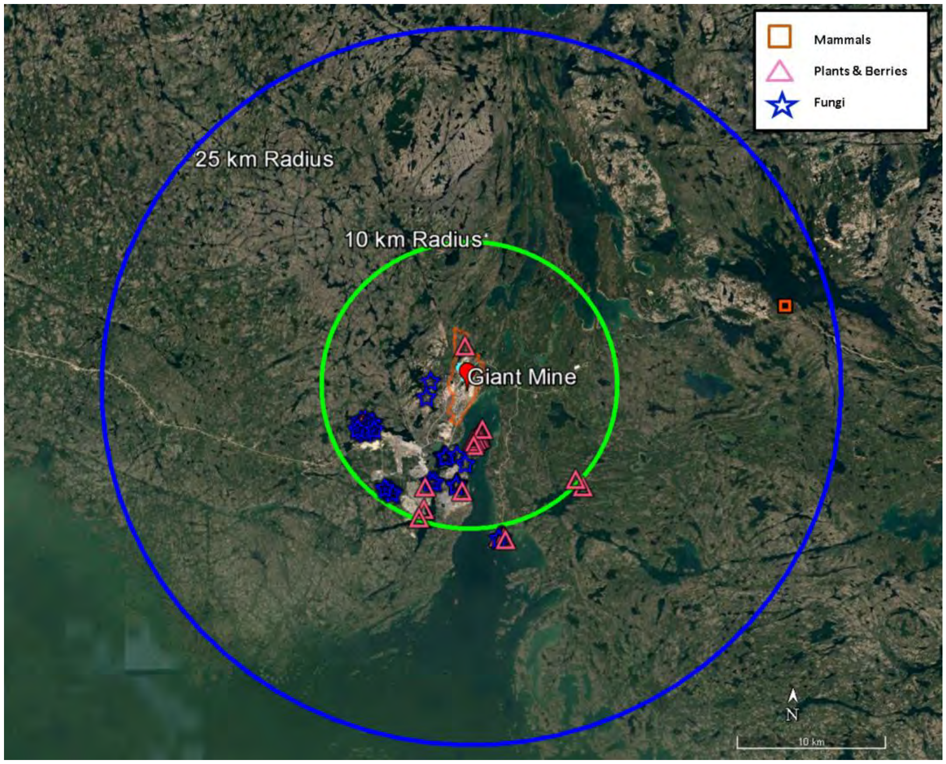

Figure P.5 Additional voluntary samples from within 50 km of the Giant Mine

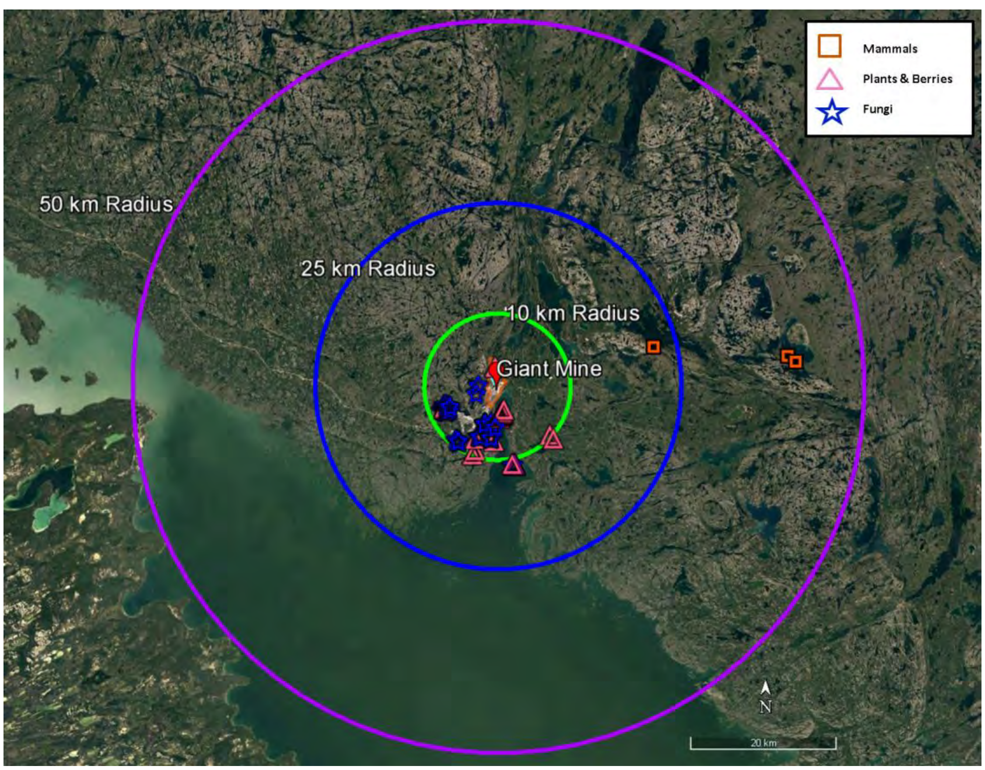

Figure P.6 Additional voluntary samples from beyond 100 km of the Giant Mine

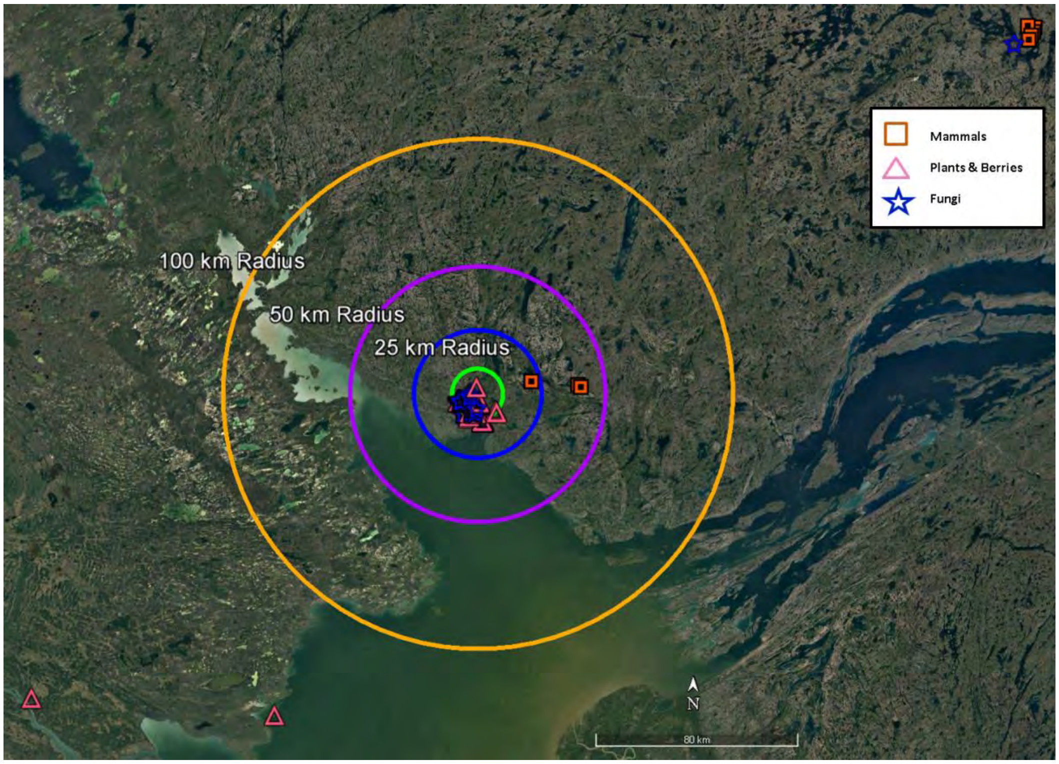

Table P.5 provides a comparison between the original arsenic EPCs used for the country food samples where additional data were available and newly derived EPCs considering the additional data. As seen from the table:

- Muskrat/beaver samples – two additional muskrat samples were provided that were obtained from background locations. The additional muskrat samples resulted in the background arsenic concentrations being reduced. However the maximum concentration and the EPC for the exposure location are both still lower than background. This finding is unchanged from the original assessment.

- Hare samples – one additional hare sample was provided from the exposure area and an additional five hare samples were from background locations. When the additional hare sample from the exposure area is considered the arsenic EPC decreases and thus the value used in the original assessment was conservative. The consideration of the five background hare samples results in a background concentration that is similar to what was used in the original assessment and thus the results are unchanged.

Table P.5 Comparison of country food EPCs from original assessment with EPCs including the additional 2017 data

Media	Location	Original Arsenic EPC (mg/kg ww)	Original dataset size	EPC with new Data (mg/kg ww)	New dataset size	EPC based on	Comment on potential action
Muskrat/ Beaver	Exposure	0.051	4	-	4	muskrat/beaver from T1 and T2	unchanged
	Exposure maximum	0.12		0.12		maximum	unchanged
	Background	1.09	1	0.38	3	muskrat/beaver from T3/T5	none, still higher than exposure EPC
Hare	Exposure	0.095	5	0.087	6	hare from T1 and T2	none, EPC went down so HHERA EPC is conservative
	Exposure maximum	0.17		0.17		maximum	unchanged
	Background	0.016	1 (based on lowest measured concentration)	0.008	5	average of T3 samples	none, some change in background, but values are low so it does not make a difference
Berries	Ndilo	0.11	6	0.09	13	average from Ndilo	none, values very similar
	Ndilo maximum	0.23		0.23		maximum	unchanged
	T1 (inc Ndilo)	0.11	14	0.10	28	average from T1	none, values very similar
	T1 (inc Ndilo) maximum	0.23		0.23		maximum	unchanged
	Beyond T1	0.04	6	0.03	8	average	none, values very similar
	Beyond T1 Maximum	0.08		0.08		maximum	unchanged
	Background	0.028	1	0.021	2	was single sample (Tibbitt lake), now average of that and T5 sample	none, values very similar

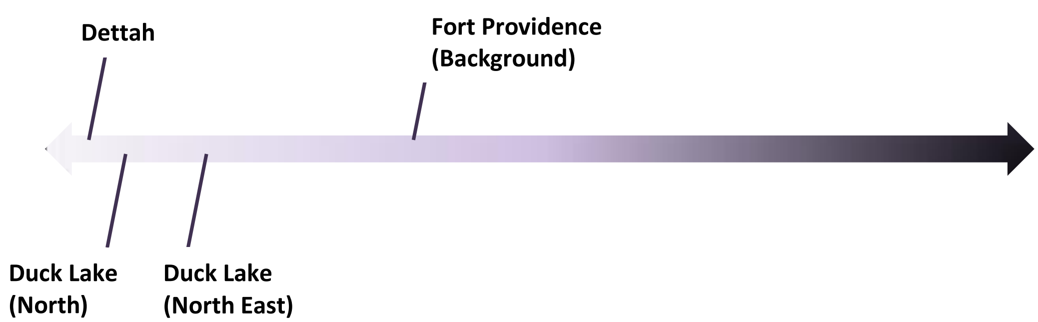
Media	Location	Arsenic Concentration Previous Avg (mg/kg ww)	Original dataset size	Average with new Data (mg/kg ww)	New dataset size	Concentration based on	Comment on potential action
Medicinal Plants	Labrador Tea - Ndilo	0.61	2	-	2	average from Ndilo	unchanged
	Labrador Tea - T1 (including Ndilo)	0.48	4	-	4	average from T1	unchanged
	Birch Syrup	0.02	1	-	1	average of all samples	unchanged
	Chives	0.82	1	-	1	single sample	unchanged
	Juniper Berries	0.18	2	0.19	3	average of samples	none, values very similar
	Spruce Gum	1.13	4	1.45	5	average of samples	none, values similar
	Rat Root	- [a]	0	0.44	3	average T1 and T2	none, below the Labrador Tea EPCs and below Rat Root background
	Rat Root Background	-	0	1.67	1	T5 sample	
	bark/twigs (birch, tamarack, cowberry, fern)	- [a]	0	0.88	5	average of samples	none, concentrations similar to labrador tea EPCs which were used
	Dandelion	-	0	5.81	1	single sample, including roots and soil	omit sample as it contains soil, which wouldn't be consumed

a assumed to be represented by Labrador Tea

- Berries – An additional seven berry samples were provided from Ndilo. The consideration of these additional samples does not change the maximum concentration nor the EPC used in the original assessment. Berry samples provided from all other locations also did not result in significant changes to the original EPCs and thus the findings of the assessment are unchanged with these additional data.

- Medicinal Plants – The additional medicinal plant data added to the dataset did not result in any significant changes to the EPCs considered in the assessment. The original assessment did not have data for rat root and these samples were collected in 2017. As seen from the table and Figure P.7, background arsenic concentrations in rat root were higher than the measured exposure locations and thus there is no incremental arsenic exposure from consuming rat root.

Figure P.7 Schematic representation of arsenic concentrations in rat root



In summary, the additional country food samples generally resulted in lower arsenic concentrations and thus the original assessment is a conservative estimate of arsenic exposure and risk. The results of the comparison of antimony data are similar and thus the conclusions of the assessment for arsenic and antimony are unchanged with the additional data.

P.3 Medicinal Tea Evaluation

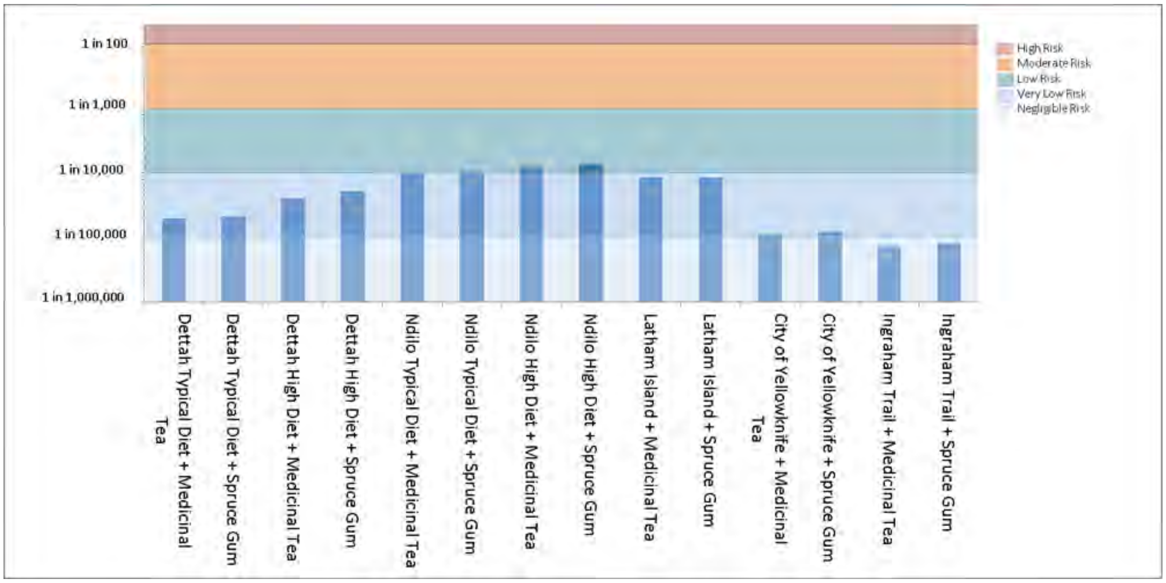
P.3.1 Medicinal Tea Evaluation Using Spruce Gum Concentrations

In the main report, the Labrador tea samples were used to evaluate the arsenic risks from drinking medicinal tea; however, medicinal plant samples collected from the spring and summer of 2017 indicated that spruce gum had the highest arsenic concentrations. Therefore an analysis was carried out using the arsenic in spruce gum (1.45 mg kg ww vs

0.61 mg/kg ww) to represent the exposure from drinking medicinal tea. The analysis involved the same assumptions as were used in the main report. Spruce gum was assumed to be 100% bioaccessible in the absence of available information.

Figure P.8 shows a comparison of the arsenic risks from using the arsenic concentrations in Labrador tea and spruce gum. As seen from the figure, there is very little difference between the two results and thus the conclusions presented in the main report are valid.

Figure P.8 Comparison of exposure from Labrador tea and spruce gum



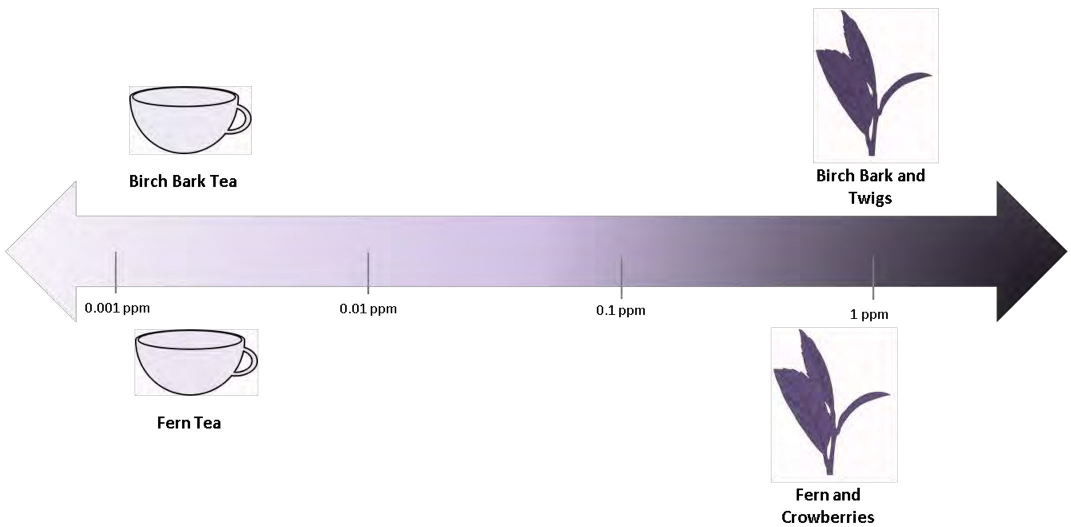
P.3.2 Medicinal Tea Evaluation Using Leaves and Tea Concentrations

Samples of tea materials collected from the spring and summer of 2017 were analyzed and also used to prepare typical medicinal teas for analysis. A birch bark tea was made by steeping 1 tablespoon (0.5 g) of bark and 1 tablespoon (0.5 g) of twigs in 1 cup of boiled water (250 mL). The bark arsenic concentration was 1.8 mg/kg ww and the concentration of arsenic in the twigs was 0.28 mg/kg ww; the resulting birch bark tea had an arsenic concentration of 1.03 µg/L (0.00103 mg/kg ww).

Similarly, a fern tea was made by steeping 1 tablespoon (0.5 g) of ferns and 1 tablespoon (1 g) of crowberries. The ferns had an arsenic concentration of 0.76 mg/kg ww and the crowberries had an arsenic concentration of 0.76 mg/kg; the fern tea had an arsenic concentration of 3.74 µg/L (0.00374 mg/kg ww).

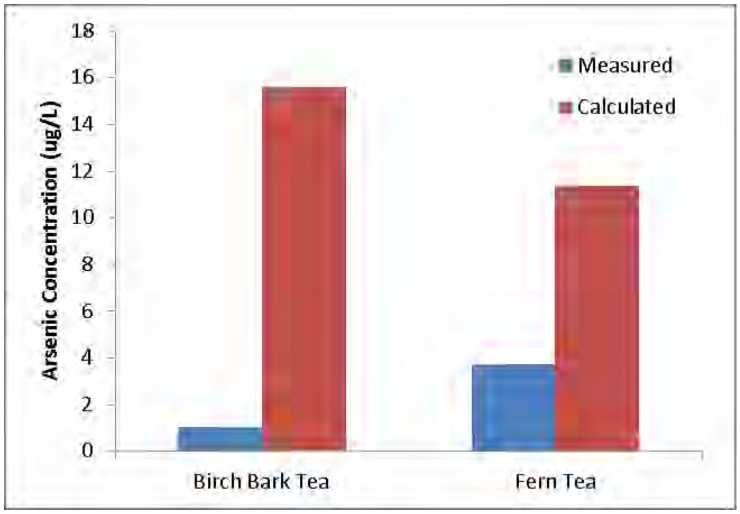
The results of the tea analysis illustrate that there are several orders of magnitude difference between measured concentrations in the tea leaf/bark materials and the tea that is produced. This is consistent with conclusions from McAuley et al. (2016), which analyzed samples of Labrador tea leaves and mint tea leaves, as well as teas made from the leaves, and found that concentrations of chemicals in the teas were orders of magnitude lower than in the vegetation. Figure P.9 provides a clear illustration of the comparison between the measured birch bark/twigs and fern/crowberries with the prepared teas.

Figure P.9 Comparison of measured arsenic concentrations in tea leaves/twigs with prepared tea drinks



The measured concentrations in birch bark and twigs and fern/crowberry tea materials were used to calculate tea drink concentrations using an approach consistent with the assessment calculations. As shown in Figure P.10, the calculated tea concentrations are considerably higher (by 3 to 15 times) than the measured tea concentrations, demonstrating that the calculation approach used in the assessment is conservative.

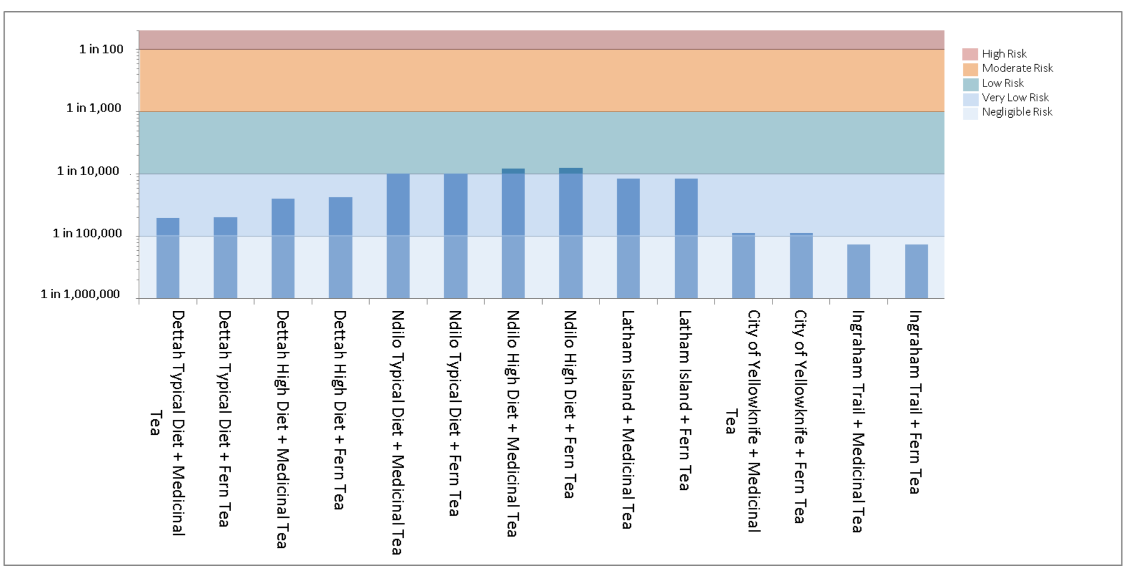
Figure P.10 Comparison of measured arsenic concentrations in prepared tea drinks with calculated tea concentrations



An analysis was carried out using the arsenic measured in prepared tea samples (maximum concentration of 3.7 µg/L from fern tea) to represent the exposure from drinking medicinal tea. The analysis involved the same assumptions as were used in the main report.

Figure P.11 shows a comparison of the arsenic risks using the measured concentration in fern tea with the results from the main report. As seen from the figure, there is very little difference between the results, thus the conclusions presented in the main report are valid.

Figure P.11 Comparison of exposure from Labrador tea and fern tea



P.4 Mushrooms

In the original HHRA, only one mushroom sample collected from Vee Lake was provided from the voluntary sampling program. Additional samples (38) were collected in the late summer of 2017 and analyzed. This section discusses the analytical results with a focus on arsenic, as that is the main COPC. Antimony concentrations that were used in the assessment are provided. As indicated in the main document, manganese exposure is dominated by supermarket food and thus an analysis is not carried out for manganese in mushrooms.

Mushroom sample locations from the voluntary sampling program are shown in Figure P.12 and Figure P.13. As seen from the figures most of the samples were collected from within 10 km of the Giant Mine. Figure P.13 shows that there were approximately 4 areas where mushroom samples were collected; area around Vee Lake, near the airport (golf course), Deh Cho Boulevard and Rat Lake area near the former Con Mine.

In addition to the data from the voluntary sample, Obst (2014) also provided information on mushrooms collected in the Yellowknife area in 2001 and 2012. These mushroom data were also considered in the mushroom evaluation as discussed below.

Figure P.12 Mushroom sample locations from voluntary sampling program

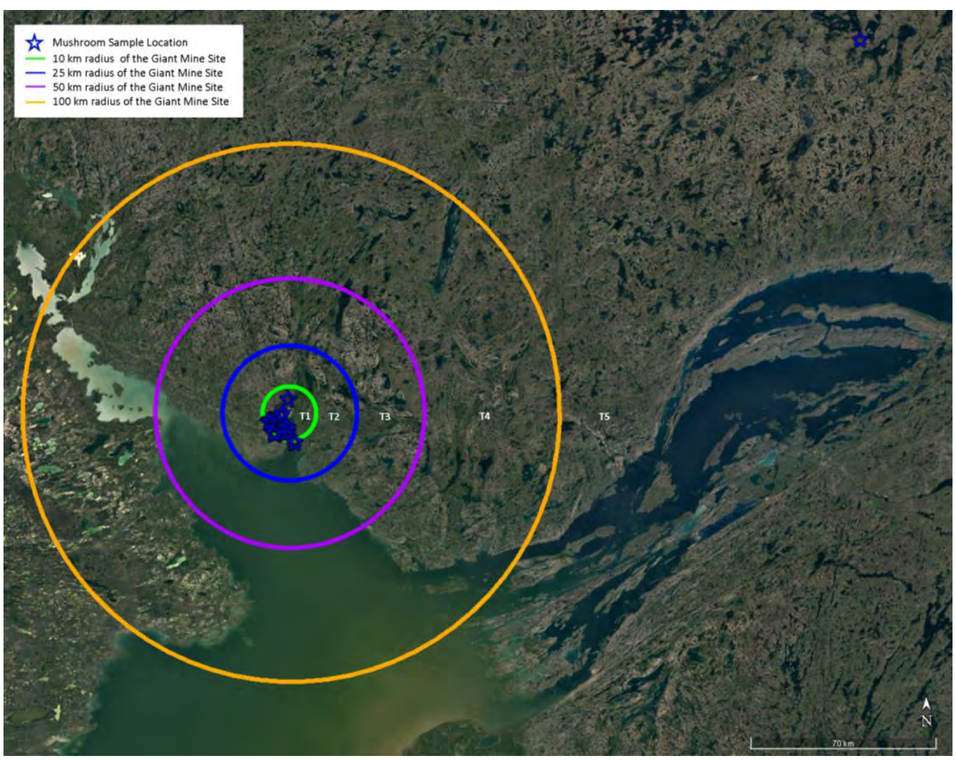


Figure P.13 Mushroom sample locations T1 and T2 from voluntary sampling program

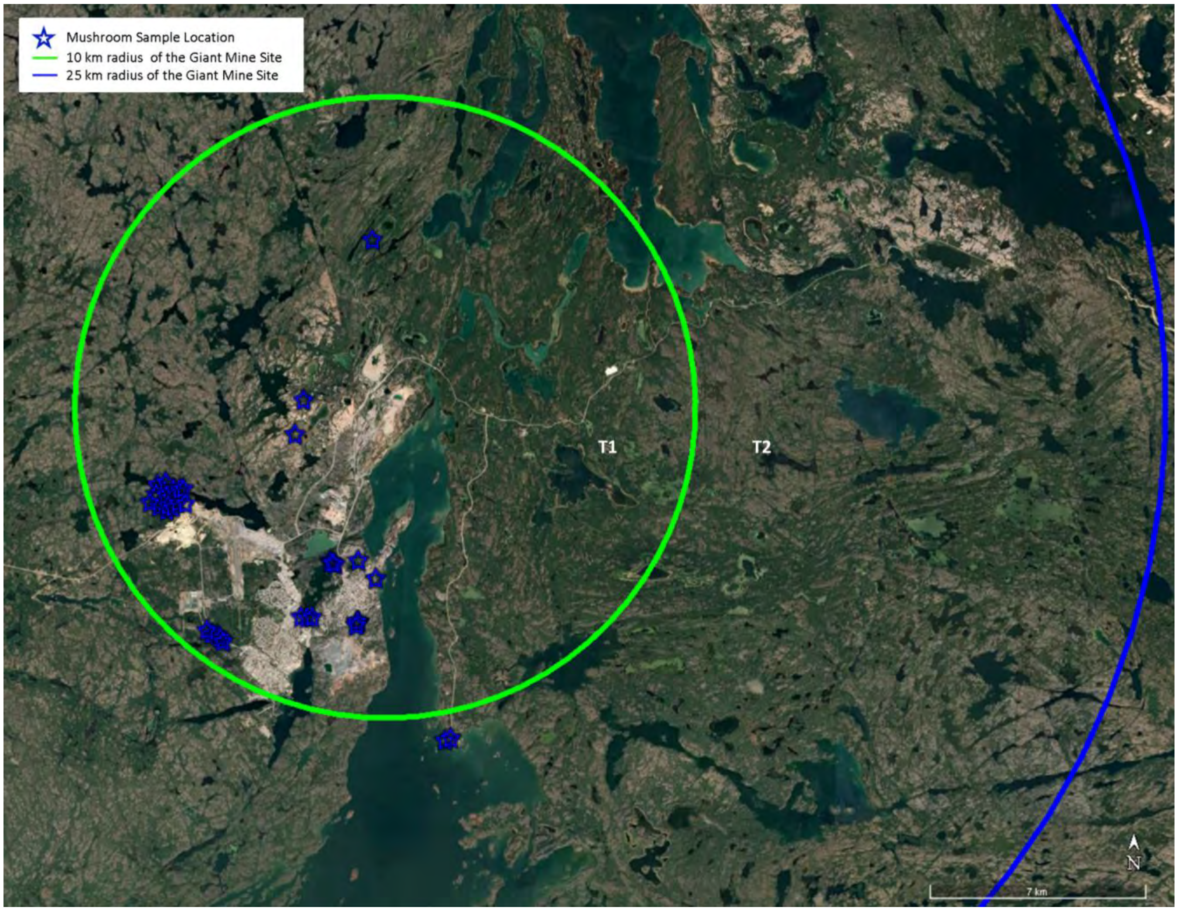


P.4.1 Consideration of Mushroom Data Sets

To allow for a more useful comparison, the mushroom data from the two studies were broken down by family as indicated in Table P.6 and the average arsenic concentrations for each family were compared as shown in

Table P.7. While direct comparisons were not available for most family of mushrooms, both the voluntary mushroom sample data and Obst mushroom data were available for *Agaricaceae, Amanitaceae, Boletaceae*, *Morchellaceae*, and *Tricholomaceae*. It should be noted that often the mushroom samples for the two studies were collected from varying distances from the Giant Mine, which complicates the comparison. In general, the average concentrations between the two studies were similar with elevated concentrations observed for *Tricholomataceae.* Average arsenic concentrations in samples collected farther from the Giant Mine were generally lower than samples collected within T1 (e.g., in the case of *Boletaceae, Morchellaceae, and*

Tricholomaceae). Based on this comparison, the two datasets were combined into a single set of mushroom data (ATTACHMENT P.2) for further evaluation.

Table P.6 Division of mushroom samples

Family	Included Sample Classifications
Agaricaceae	Agaricus, Meadow Mushroom
Amanitaceae	Amanita, Fly Agaric
Bankeraceae	Sarcodon
Boletaceae	Bolete, Leccinum
Coprinaceae	Shaggy Mane, Tippler's Bane
Helvellaceae	False Morel
Hymenochaetaceae	Chaga
Lycoperdaceae	Puffball
Morchellaceae	Morchella, Morel
Russulaceae	Lactarius
Suillaceae	Suillus, Gomphidius, Fuscoboletus
Tricholomataceae	Tricholoma, Clitocybe, White Matsutake

Table P.7 Comparison of Obst and voluntary sampling mushroom data

Family	Study	N	Average Arsenic Concentration (mg/kg ww)	Comment
Agaricaceae	Summer 2017	4	4.5	All samples from T1
	Obst (2014)	10	7.1	All samples from T1
Amanitaceae	Summer 2017	2	0.55	All samples from T1
	Obst (2014)	5	0.72	Samples from T1 and T5
Bankeraceae	Summer 2017	2	1.7	Samples from T1 and T3
	Obst (2014)	0	-	
Boletaceae	Summer 2017	9	0.83	All samples from T1
	Obst (2014)	47	0.40	Samples from T1, T2, T3, T4 and T5
Coprinaceae	Summer 2017	0	-	
	Obst (2014)	9	12	All samples from T1
Helvellaceae	Summer 2017	0	-	
	Obst (2014)	5	0.03	Samples from T3 and T4
Hymenochaetaceae	Summer 2017	2	0.05	Samples from T1 and T2
	Obst (2014)	0	-	
Lycoperdaceae	Summer 2017	0	-	
	Obst (2014)	3	9.10	All samples from T1
Morchellaceae	Summer 2017	2	0.70	Samples from T1 and T5
	Obst (2014)	31	0.12	Samples from T3, T4 and T5
Russulaceae	Summer 2017	1	0.41	Sample from T1
	Obst (2014)	0	-	
Suillaceae	Summer 2017	15	0.73	All samples from T1
	Obst (2014)	0	-	
Tricholomataceae	Summer 2017	3	131	All samples from T1
	Obst (2014)	13	23	Samples from T1, T2, T3 and T4

P.4.2 Arsenic Concentrations in Mushrooms Used in Calculations

The combined voluntary sampling/Obst mushroom dataset was then further analyzed to generate concentrations for use in the human health calculations. Given the fact that *Tricholomataceae* is known to be an arsenic accumulator and therefore have the highest concentrations, arsenic in mushroom concentrations were derived using the combined dataset excluding *Tricholomataceae* samples and for *Tricholomataceae* samples only.

Mushroom arsenic concentrations are presented in Table P.8 for the non-*Tricholomataceae* samples and *Tricholomataceae* only samples from the combined dataset. As seen from the table, the arsenic concentrations in the *Tricholomataceae* samples are at least an order of magnitude higher than for other mushrooms collected at the same distance from the Giant Mine. Concentrations of arsenic in all the mushroom samples collected from T3 which are at a distance of 25 km from the Giant Mine are essentially the same as background concentrations at 50 km distance from site. Obst (2014) indicated that people should only eat mushrooms from a distance greater than 50km from the Giant Mine. The mushroom data indicate that mushrooms at a distance of 25km are at background concentrations.

Table P.8 Average arsenic concentrations in mushrooms at different distances from the Giant Mine

Location	Without *Trichcolomataceae*		*Trichcolomataceae* Only	
	N	Average Arsenic Concentration (mg/kg ww)	N	Average Arsenic Concentration (mg/kg ww)
Background (> 50 km of Giant Mine)	46	0.13	3	7.4
T1 (Within 10 km of Giant Mine)	74	3.6	6	106
T2 (10 to 25 km of Giant Mine)	4	0.19	1	11
T3 (25 to 50 km of Giant Mine)	24	0.14	6	4
T4 (50 to 100 km of Giant Mine)	11	0.04	-	-
T5 (> 100 km of Giant Mine)	35	0.17	-	-

The T1 location includes 4 areas: around Vee Lake, near the airport (YK golf course), Deh Cho Boulevard and around Rat Lake. The Health Department has an advisory to not eat mushrooms and berries from around Rat Lake and thus these samples were removed from the dataset. With the exclusion of the mushroom samples around Rat Lake the arsenic concentration is calculated as 0.76 mg/kg ww. This concentration was used in the calculations.

P.4.3 Mushroom Consumption Rates Used in Calculations

Obst (2014) provided information on the annual consumption of mushrooms based on 26 harvesters. These data were collected over a year between 1998 and 1999 and are summarized in Table P.9. As seen from the table, the majority of the harvesters ate less than 5 kg a year of mushrooms with 10 harvesters eating less than 3.5 kg.

Table P.9 Mushroom consumption by harvesters in Yellowknife area

Kilograms/year eaten	Number of People
15	2
11	1
9 to 9.5	3
7-8	3
4 to 5	7
<1 to 3.5 kg	10

Note: obtained from spreadsheet Mush.Final.01.xls

The average yearly consumption of mushrooms reported in Table P.9 is 5.5 kg. In addition, Obst (2014) provided information on 1350 residents in Yellowknife who consume mushrooms (see Table P.10). Based on this information the average yearly consumption of people who eat mushrooms in Yellowknife is 1.1 kg/yr.

Table P.10 Mushroom consumption by residents in Yellowknife area

Kilograms/year eaten	Number of People
10 to 15	10
5 to 10	25
2 to 5	40
1 to 2	100
0.5 to 1	175
0.07 to 0.5	1000

Note: obtained from spreadsheet Mush.Final.01.xls

The information provided also indicated that people harvested mushrooms 3.5 years out of every 5 years as generally every 1.5 years there are no mushrooms to harvest.

The information from the harvesters seemed to skew the information high and it was assumed based on all this information that people in Yellowknife who eat mushrooms would eat 1.5 kg over a 6 month period or about 7.5 grams ww per day.

For consideration of the intake of *Tricholomataceae*, it was assumed that 20% of the edible mushrooms would consist of *Tricholomataceae* since they are only harvested in late September and October. This results in an intake rate of 1.5 g *Trichlomatacae* (ww)/d.

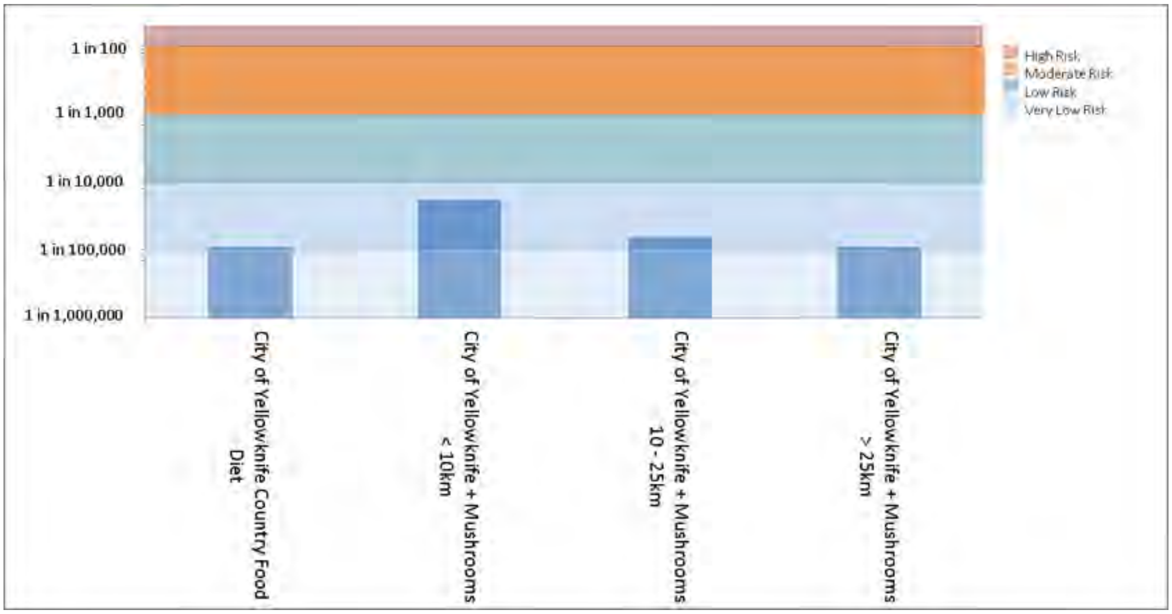
The calculation assumes that people would eat mushrooms every day as adults for 60 years (i.e., from 20 to 80 years of age) and that people from the City of Yellowknife, which includes the Metis, eat mushrooms. The YKDFN indicated that they do not eat mushrooms.

P.4.4 Results

In determining the risks from arsenic exposure, bioaccessibility and speciation assumptions for mushrooms were used. These values were provided in the main document. The arsenobetaine (non-toxic form) was considered to be 34% of the total arsenic and thus the remaining arsenic was assumed to be in the toxic form. A bioaccesibility value of 70% was then applied to the remaining arsenic fraction.

Figure P.14 shows the associated incremental cancer risk for eating all mushrooms with the exception of *Tricholomataceae*.

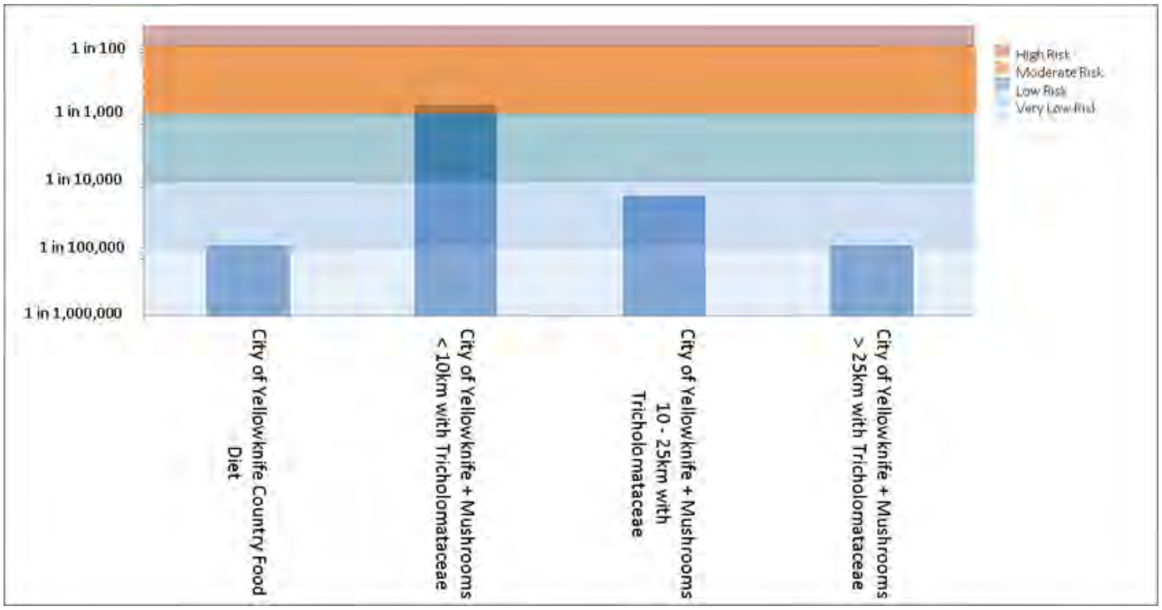
Figure P.14 Incremental arsenic risks associated with mushroom consumption



The figure provides the base case for the City of Yellowknife for comparison purposes. The results indicate that if someone eats 1.5 kg mushrooms a year from locations beyond 25 km of the Giant Mine that there is no incremental arsenic risk as the arsenic concentrations are at background. Eating mushrooms from between 10 km and 25 km of the Giant Mine results in risks in the low end of the very low risk area and eating 1.5 kg of mushrooms a year from within 10km of the Giant Mine increases the risk, however, risks are still in the very low range and are similar to having x-rays.

Figure P.15 shows the associated incremental cancer risk for eating *Tricholomataceae* only. It was assumed that people eat about 300 g/year of this high arsenic accumulator for 40 years. As seen from the figure, risks are in the moderate range for eating these high arsenic accumulating mushrooms for areas such as the golf course that is within 10 km of the Giant Mine. There is no incremental arsenic risk from eating high arsenic accumulating mushrooms at distances greater than 25 km from the Giant Mine.

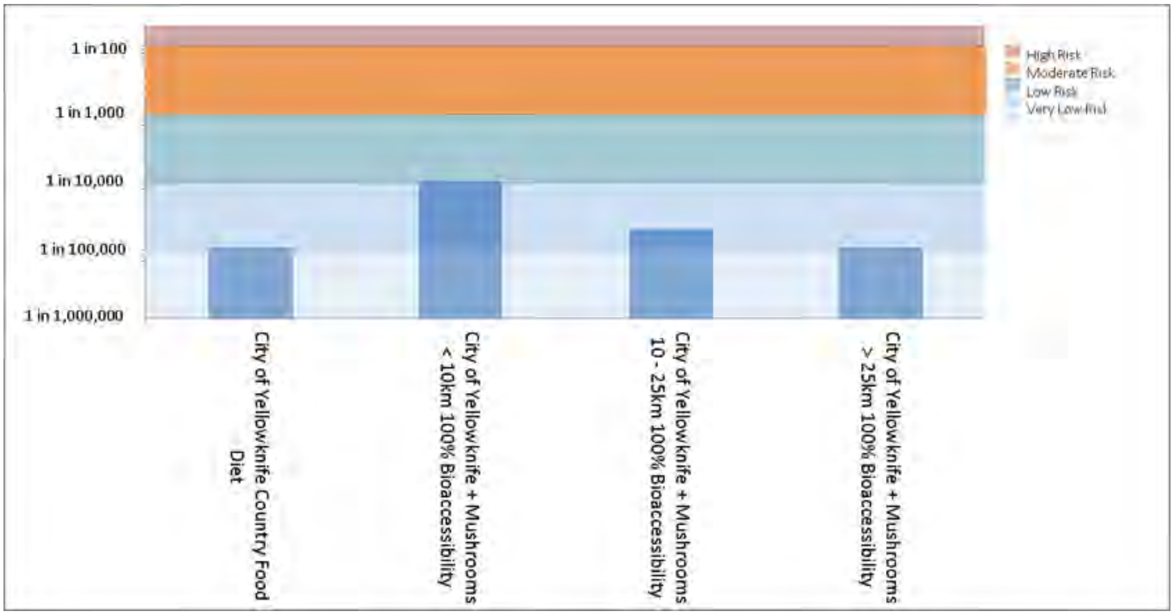
Figure P.15 Incremental arsenic risks associated with *Tricholomataceae* consumption



P.4.5 Speciation and Bioaccessibility

To evaluate the potential effect of bioaccessibility assumptions on the calculated incremental cancer risk due to mushroom consumption, a separate calculation was undertaken assuming that 100% of the arsenic was bioaccessible. While the bioaccessibility of the mushrooms was assumed to be 100%, the arsenobetaine content (non-toxic portion) was still taken into account in these calculations. The results of this calculation (see Figure P.16) show that assuming 100% bioaccessiblity of arsenic in mushrooms increases the risks slightly resulting in the risks of eating mushrooms from within 10 km of the Giant Mine tipping into the low end of the low risk range.

Figure P.16 Incremental arsenic risks associated with mushroom consumption – 100% bioaccessibility



The above results of very low risks for mushroom exposure were calculated assuming that people ate 1.5 kg of mushrooms a year from each of the locations. Additional calculations were carried out to determine how many mushrooms can be consumed from areas within 10 km of the Giant Mine and between 10 km and 25 km in order to represent a negligible risk. Table P.11 shows that in order to have a negligible risk from arsenic exposure people should only eat about 300 g of mushrooms a year from with 10 km of the Giant Mine. Within 10 to 25 km of the Giant Mine they can consume about 3.2 kg of mushrooms a year and still be at a negligible risk.

Table P.11 Annual consumption of mushrooms associated with negligible risk level

Mushroom Source	Mushroom Ingestion Rate (kg/year) for a Negligible Risk Level (1×10^{-5})
Within 10 km of Giant Mine (T1)	0.3
10 to 25 km of Giant Mine (T2)	3.2
> 25 km (T3 to T5)	Unlimited

For high arsenic accumulators such as *Tricholomataceae,* only about eight grams can be eaten each year from within 10 km of the Giant Mine without incremental cancer risks above the negligible range.

P.4.6 Antimony Results

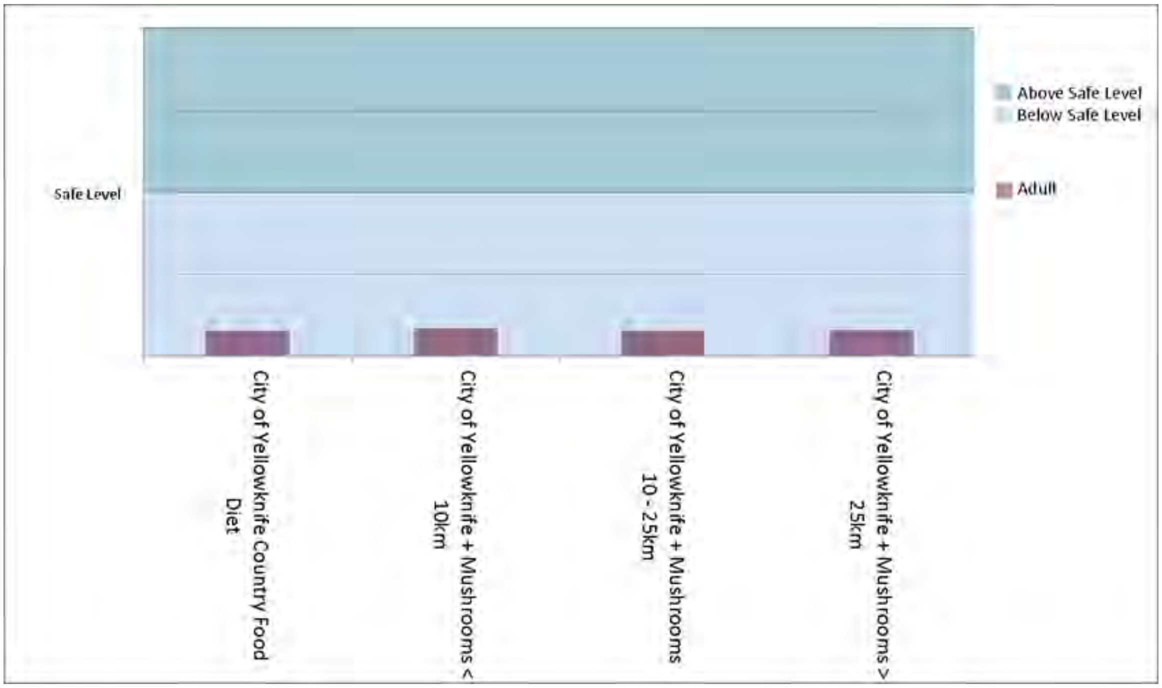
The above discussion focused on arsenic. This section provides the concentrations of antimony in mushrooms based on the combined dataset (see Table P.12) and presents the results for mushroom consumption (see Figure P.17). Table P.12 shows that in mushroom samples that the antimony concentration is similar to background for all locations except with in the 25 km to 50km distance from the Giant Mine. For *Tricholomataceae,* antimony concentrations are within background at distances greater than 10km from the Giant Mine.

As seen from the Figure P.17, antimony exposure from eating mushrooms at different distances from the Giant Mine do not add much additional exposure and are all below the safe level. It is noted that all other pathways of exposure as discussed in the main report are presented in the figure.

Table P.12 Antimony concentrations in mushrooms

Location	Without *Trichcolomataceae*		*Trichcolomataceae* Only	
	# of Samples	Average Antimony Concentration (mg/kg ww)	# of Samples	Average Antimony Concentration (mg/kg ww)
Background (> 50 km of Giant Mine)	46	0.05	3	0.014
T1 (Within 10 km of Giant Mine)	74	0.05	6	0.13
T2 (10 to 25 km of Giant Mine)	4	0.007	1	0.012
T3 (25 to 50 km of Giant Mine)	24	0.012	6	0.009
T4 (50 to 100 km of Giant Mine)	11	0.073	-	-
T5 (> 100 km of Giant Mine)	35	0.02	-	-

Figure P.17 Exposure to antimony from consumption of mushrooms



P.5 Additional Scenarios

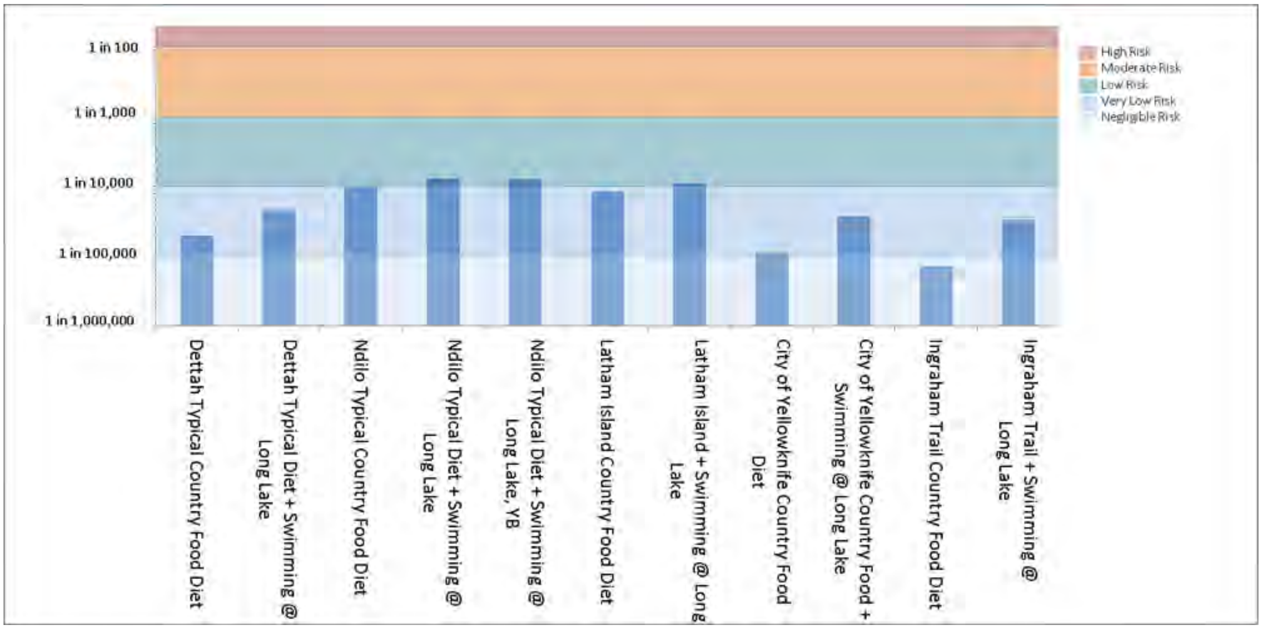
P.5.1 Long Lake Exposure from Swimming and Wading

During meetings to present the draft risk assessment, the YKDFN and other residents indicated the need to see additional analyses for exposure at Long Lake. Figure P.18 shows the results of these additional analyses. The different analyses involved:

- residents of Ndilo swimming in Long Lake;
- residents of Ndilo wading in Yellowknife Bay and Long Lake;
- residents of Latham Island swimming in Long Lake; and
- residents of Ingraham Trail swimming in Long Lake.

Figure P.18 shows the scenario for the City of Yellowknife that was presented in the main report as well as the additional scenarios. The results show that swimming in Long Lake and incidental ingestion of water while swimming increases the risk from arsenic exposure; however, results are in the very low risk range for all locations with the exception of Ndilo where the risks are in the low end of the low risk range.

Figure P.18 Incremental arsenic risks associated with wading and swimming in Long Lake



P.5.2 Yellowknife River Exposure from Swimming and Wading

There is a day use area along the Yellowknife River and members of the YKDFN requested that an analysis be completed of people wading and swimming in the Yellowknife River. There were some surface water samples and sediment samples in the Yellowknife River near to the day use area and these samples were considered to be a representation of conditions in the that people would encounter during swimming and wading activities.

Figure P.19 shows the two surface water sample locations near the mouth of the Yellowknife River that were considered as well as the two upstream background locations. Table P.13 provides the summary of the data. As seen from the table, the arsenic and antimony concentrations in the Yellowknife River are considered to be at background concentrations.

Figure P.20 shows the sediment sampling locations considered for the day use area and Table P.14 provides a summary of the data. As seen from the table, the maximum arsenic concentration was found to be 38 mg/kg, which is similar to the shallow sediment arsenic concentrations near Ndilo.

Figure P.19 Surface water samples in Yellowknife River

Table P.13 Summary of surface water concentrations from Yellowknife River

COPC	Back-ground (mg/L)	N	N<MDL	Surface Water Concentration (mg/L)				
				Min	Max	Average	Standard Deviation	95th Percentile
Antimony	0.00005	7	7	0.00003	0.0002	0.0001	8.9×10^{-5}	0.0002
Arsenic	0.0009	7	0	0.0003	0.0005	0.0004	5.1×10^{-5}	0.0005

Figure P.20 Sediment samples in Yellowknife River

Table P.14 Summary of sediment concentrations from Yellowknife River

COPC	Back-ground (mg/kg)	N	N<MDL	Sediment Concentration (mg/kg)				
				Min	Max	Average	Standard Deviation	95th Percentile
Antimony	0.44	6	0	0.05	1.7	0.87	0.62	1.6
Arsenic	6.4	6	0	6.2	38	18	10	32

Figure P.21 shows the scenario for members of Ndilo and Dettah swimming and wading in the Yellowknife River for their lifetime. The results show that swimming and wading in the Yellowknife River does not change the incremental arsenic risks very much.

Figure P.21 Incremental arsenic risks associated with wading and swimming in Yellowknife River

APPENDIX Q

CONCORDANCE WITH EA FINDINGS

TABLE OF CONTENTS

LIST OF TABLES

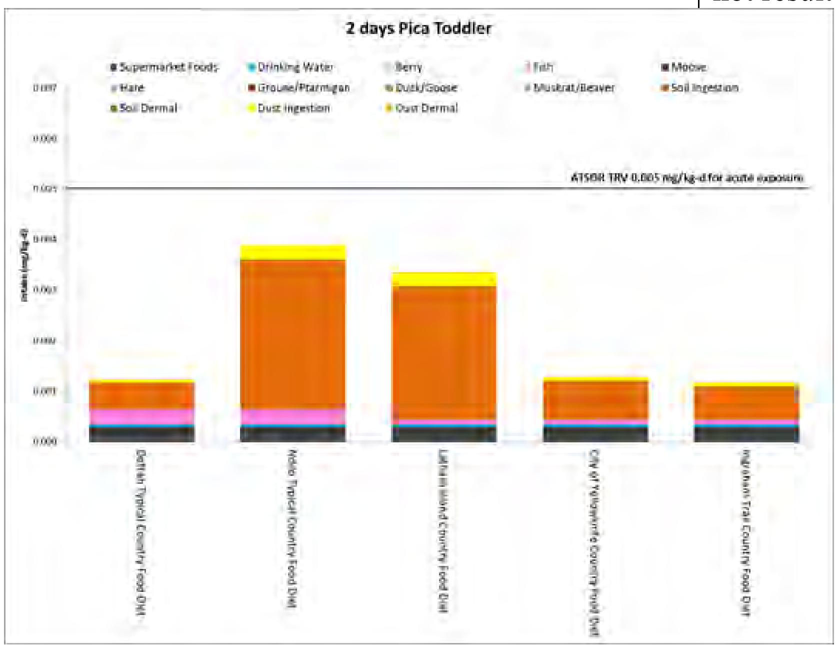
APPENDIX Q: CONCORDANCE WITH EA FINDINGS

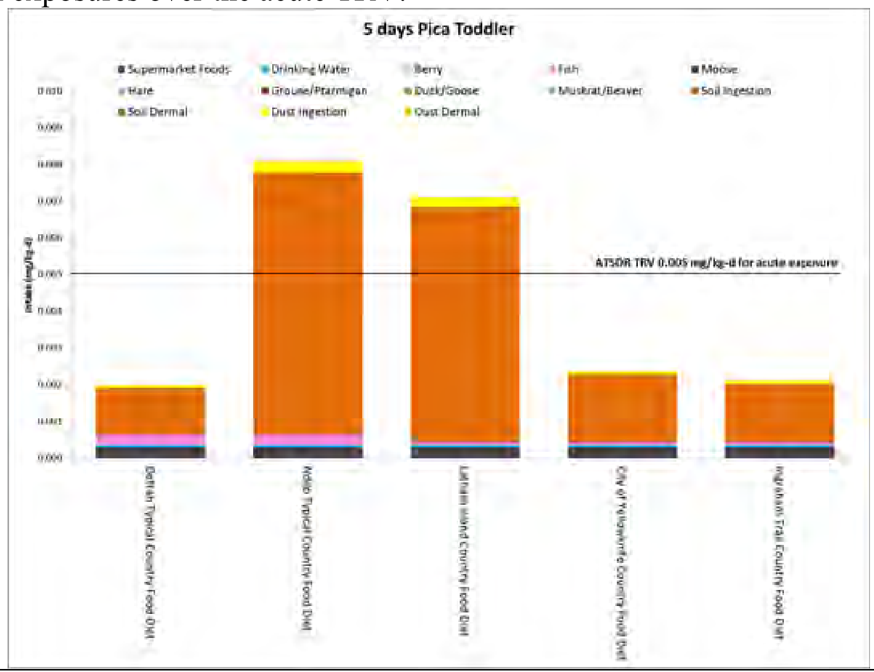
The human health and ecological risk assessment for the Giant Mine is intended to fulfil the requirements of Measure 10 from the Environmental Assessment, including addressing the requirements specified in Appendix F of the Report of Environmental Assessment. Table Q.1 provides information as to how the HHERA fulfils the requirements specified in Appendix F of the Report of Environmental Assessment.

Table Q.1 Concordance with EA findings

Comment	Where Addressed
Include a critical review of the 2006 Tier II risk assessment [PR#139b] and the previous screening reports, and based on this, consider the valid results of the Tier II risk assessment in its recommendations or discussions.	This was conducted by Stantec (2015) and discussed in the Problem Formulation that was used to define the scope of work for the HHERA.
Consider baseline historical data (CPHA 1977), current Canadian Guidelines for human and environmental exposures to arsenic, and baseline studies.	Historical data and current data were considered in developing baseline/background to be used in the HHERA. Section 2 and Appendices B and C discuss all the data used in the HHERA. Comparisons to Canadian Guidelines are provided in Appendix D and Section 3.2 of the report.
Review the existing distribution of concentrations of arsenic in various media effecting humans and the environment of Yellowknife and surrounding communities and compare these with the range of concentrations and exposures in the current literature on human and environmental health impacts.	Historical data and current data were considered in the HHERA. Section 2 and Appendix B of the HHERA discuss all the data that were used in the HHERA. A comparison of chemical concentrations in soil and water to established guidelines provided by various sources including the CCME Environmental Quality Guidelines, Health Canada's Drinking Water guidelines and background were undertaken in the report. Arsenic concentrations in country foods in the Yellowknife area and surroundings were generally higher than those found in similar foods available on the Canadian market. Arsenic concentrations in fish were within the range of concentrations reported in commercial freshwater fish. Arsenic concentrations in moose samples were similar to samples collected from the Yukon (see Section 3.3.6).
Conduct a Risk Assessment Sensitivity Analysis that completes the evaluation of pre-born, toddler, child, teen and adult receptors in all four localities of the mine site (N'dilo / Latham Island, Yellowknife and Dettah) without combining these receptors into a composite receptor.	Section 3.5 of the report presents the results for toddlers (the most exposed receptors) for exposure to non-carcinogenic constituents such as antimony and manganese. The risks from arsenic are provided for a composite receptor as required by Health Canada guidance. The detailed results for the exposure to COPC for different life stages, including toddler, child, teen, adult and elders for total arsenic, antimony and manganese are presented in Appendix F. As discussed in Appendix E, infants were not included as COPC are expected to be low in breast milk. The toxicity reference values used in the assessment are derived to be protective of sensitive life stages including pregnant women (pre-born) and the elderly.

Comment	**Where Addressed**
Evaluate impacts on toddlers considering potential soil pica episodes and acute arsenic toxication (per *Calabrese, et al*. 1997). The results of this component of the risk assessment should be used to inform and assist the health effects monitoring program.	The U.S. EPA (2011) indicates that pica behavior in a toddler results in the ingestion of approximately 1000 mg of soil per day. The Agency for Toxic Substances and Disease Registry (ATSDR 2007) provides an acute arsenic TRV of 0.005 mg/kg-d based on acute poisoning from arsenic laced soy sauce. The following figures show the arsenic intakes for a pica toddler for 2 days exposure a week and 5 days exposure a week. The results show that if a toddler exhibits pica behavior 2 days a week, the arsenic exposure at all locations in Yellowknife are below the acute TRV. Toddlers in Ndilo and Latham Island are the most exposed. At 5 days pica exposure, the exposures in Ndilo and Latham Island exceed the acute TRV. 3 days pica behavior results in intakes below the acute TRV. At all other locations, pica behavior over a week does not result in exposures over the acute TRV.





Comment	Where Addressed
Consider a range of current cancer slope factors to evaluate and explain the results of the analysis. This will: a. use the most conservative approach to most accurately reflect potential increased susceptibility from early life exposures to carcinogens; b. include a particular focus on the Yellowknives Dene and lifetime Yellowknife residents, who are most likely to reside within the realm of exposure to arsenic from the Giant Mine Remediation Project for their entire lifetime; and c. consider long term cumulative exposure from pre-born to adult stages	The evaluation of exposure to arsenic considered a receptor that lives their entire life at various locations in Yellowknife including the Yellowknives Dene living in Ndilo and Dettah. The exposure scenarios are presented in Section 3.3 and the results in Section 3.5. Detailed information on the exposure assessment are provided in Appendix F with the detailed results being presented in Appendix H. Section 3.5.4 of the report provides an analysis of the use of 2 different slope factors from Health Canada and the U.S. EPA on the evaluation. The toxicity reference values used in the assessment are derived to be protective of sensitive life stages including pregnant women (pre-born) and the elderly.
Use data that reflect site-specific local concentrations that people are exposed to, instead of regionally or territorially averaged measures, for any of the consumed items in the models. This must consider: d. concentrations in local soils, sediments, drinking water, traditional foods and store-bought food as well as local aerial emissions. In the case of wide ranging animals used as food such as caribou, it is permissible to use data that are relevant to the local hunting patterns of the receptors; e. worst case scenario exposures as well as local (not regional or territorial) averaged exposures.	Local data on air, soil, water (both surface water for swimming and drinking water) as well as food were used in the assessment. Voluntary samples of country foods were provided to the study team and analysed and used in the HHRA. The detailed results are provided in Appendix B and Appendix P. Section 2 of the report also provides a summary of the various studies and maps of the locations. The Sensitivity analysis presented in Section 3.5.3 explores a number of worst case scenarios.

Comment	Where Addressed
Compare the identified arsenic levels with thresholds from a range of guidance available for the use of various Toxicological Reference Values and their equivalents (HC 2010), identifying where Toxicological Reference Values and equivalents are exceeded, and interpreting the importance of any such exceedances	The Health Canada TRVs were used in the assessment and Health Canada guidance was followed in the HHRA. Graphical representation and interpretation of the results in comparison to Health Canada TRVs are presented in Section 3.5.
Consider potential impacts of soil concentrations on receptors, and apply the results to the human health monitoring program.	The exposure from soil pathways at various residential locations around Yellowknife were considered in the HHERA report. Section 3.3.7 of the report presents the exposures by the various pathways including soil. Appendix F presents the detailed results. Section 3.5 presents the total risks for each location and Appendix H provides the detailed results. The team conducting the Health Effects Monitoring Program will consider these results when evaluating their findings.
Use recently collected water data to reflect current conditions, instead of the surface water data from the late 1990s in some localities used in the 2006 Tier II study.	Section 2 and Appendix B of the HHERA report discuss all the data for drinking water sources including the municipal drinking water supply and Yellowknife Bay that were used in the HHERA. Data available in the last 5 years were used in the assessment.
Provide guidance and interpretation of the current and predicted exposures, subsequent human health risk, and risk management to the health effects monitoring program. This will include exposure data with ambient concentrations in soil, water and air, geographically displayed and interpolated if feasible, to indicate where risk is presented to human populations.	Section 3.3 of the HHERA provides maps showing the samples considered in the HHERA for different locations and media. In addition the derived exposure point concentrations (EPCs) for both the current and future conditions are presented. Section 3.5 of the report provides the risks from exposure to arsenic, antimony and manganese in different graphical formats.
Evaluate indirect effects of potential exposures to arsenic on wellness, including stress effects	The Stress study is being carried out by a different team and is a separate study from the HHRA.
